GENERAL

"Grant that the phenomena of intelligence conform to laws; grant that the evolution of intelligence in a child also conforms to laws; and it follows inevitably that education cannot be rightly guided without a knowledge of those laws."

HERBERT SPENCER.

PREFACE TO THE FIRST EDITION.

THE present Text Book has been prepared specially for students preparing for the final examination for the Elementary School Teacher's Government Certificate. Such students will find in it material amply sufficient to answer any question likely to be set on "The Processes of Reasoning," as in drawing it up it has been thought advisable to err on the side of *too much*, rather than on the side of *too little*, for the purpose in view. The book is the outcome of considerable experience in preparing students for the "Certificate" Examination.

The arrangement of the first few chapters is due in the main to the valuable criticisms and suggestions of Professor CUSACK.

It is hoped that students other than those for whom it is specially prepared will find the book useful as a fairly complete introduction to the Study of Logic.

197486

GENERAL

PREFACE TO THE SECOND EDITION.

In preparing the Second Edition of this Text Book, it was thought advisable, in the light of greatly extended experience in teaching the subject, to entirely rewrite and greatly enlarge it. The present Edition may therefore be regarded as a new book. The First Edition has proved useful to thousands of students. The hope of the writer is that in its present form the book will prove more useful to even a greater number.

S. B.

September 1st, 1899.

TABLE OF CONTENTS.

CHAPTER		PAGE
I.	Reasoning	1
II.	Examples of Reasoning	7
III.	Uses of Logic	13
IV.	The Parts of a Deductive Argument...	17
V.	The Laws of Thought	23
VI.	Terms	30
VII.	The Twofold Meaning of Terms	40
VIII.	Classification of Propositions	46
IX.	Propositions and Distribution of Terms	55
X.	Immediate Inference—Opposition	66
XI.	Immediate Inference—Eduction	74
XII.	The Predicables	86
XIII.	Definition	93
XIV.	Logical Division...	99
XV.	The Syllogism	105
XVI.	Figure and Mood	118
XVII.	Reduction	125

PRINCIPLES OF LOGIC.

CHAPTER I.

Reasoning.

There has never been a time in the history of the human race when knowledge has been regarded as a possession of greater importance than it is at the present day. It is true, that in education mental training is said to be the object aimed at rather than the mere acquisition of knowledge, yet when it is remembered that mental training is essentially a fashioning of the mind so as to make it capable of more readily acquiring knowledge than would be possible without such training, it becomes clear that in education directly or indirectly the acquisition of knowledge is the main, if not the sole, object. The possession of greater knowledge on the part of the human race has brought it about that to-day "millions find support where once there was food only for thousands", and that to the meanest of these millions comforts and pleasures are possible such as formerly were unattainable by the most powerful.

We all are ready to allow the transcendent importance of knowledge and, at the same time, are possibly inclined

to take pride in the thought that our knowledge is far greater than that of our fathers.

"We think our fathers fools, so little did they know,"

says Pope, and we are quite ready to agree with him; and yet how few of us stop to ask ourselves the question, "How has this increase of knowledge been brought about?" Granted the supreme importance of knowledge, the question "How is knowledge acquired?" is surely one that deserves to be answered. It is clear that we learn that honey is sweet by tasting it, that iron is hard by feeling it, that a buttercup is yellow by looking at it, and so on.

In these cases we gain knowledge by the use of our senses. The mind is seated in the brain and has communication with the outside world only by means of the senses. These senses are means of ingress to the mind; they are, as indeed they have been called, "the portals of knowledge". Could there be such a thing as a human being endowed with none of the senses, his mind (if we could say he had a mind) would inevitably be a perfect blank. Hence the immense importance in education of training the senses.

A little thought will, however, serve to make it clear that some of the knowledge that we possess has not been acquired directly through the use of our senses. Thus, the sun is known to be a globe many times larger than the earth, but our sense of sight alone would lead us to believe that it is a ball having a diameter of, at most, a few feet; and mere observation would tell us that the moon is as large as the sun. If we trusted to our senses alone, we should believe that the stars are mere points, that the sun moves daily in a curve from east to west, that the surface

of the earth is flat, and many other things which, with our present knowledge, we know to be false.

Further, it is evident that many facts known to be true could not from their very nature be known by the use of the senses alone. Thus we know that we are mortal, but no amount of observation alone could tell us this, for no one could be known to be mortal until he died; and hence no one could ever know that he himself was mortal. The mind, then, must possess some other means of acquiring knowledge. What is this means? An example will make it clear. A child sees a dog and learns by the actual use of his sense of sight that the dog has four legs. His sight tells him the same fact of several other dogs. From this he concludes that all dogs have four legs.

In this case the child makes use of the facts supplied by his sense of sight, and out of them he evolves an entirely new fact, viz., that all dogs have four legs. It is quite clear the child would never be able to learn this fact by observation alone, for he would never be able to see all dogs. He has gone through a process altogether different from that of observation, he has *reasoned*. That power possessed by the human mind of taking certain given facts and from them deducing new facts is called the *Reasoning Faculty;* the process by which such new facts are reached is called *Thinking* or *Reasoning*. To reason, then, is to obtain additional facts out of given facts. *Sensation* and *Reasoning* are the two, and the only two, means by which the mind can possibly obtain knowledge.

It is evident from what is said above that in order to reason we must first possess knowledge from which to reason. Reason cannot produce knowledge without having

raw material to work upon. This raw material is ultimately derived from sensation, and when used by Reason to establish new truths, it is called the *data** or *premisses*. The truth reached by reasoning is said to be *inferred* from the given premisses. The inferred truth or inference is often called the *conclusion*.

When a conclusion follows properly from its premisses, that is, in such a manner that, granted the truth of the premisses, the conclusion is necessarily true, it is said to be *valid*. The meaning of this word should be carefully noticed, as students frequently fall into the error of regarding any conclusion as valid if they know it is true. The distinction between the words *valid* and *true* will become clear on reading the examples of reasoning in Chapter II. At present it is sufficient to note that a valid conclusion may be a false one, if one or more of the premisses be false; and that on the other hand, a conclusion may happen to be true and yet not be valid if it does not follow properly from the premisses.

Everybody is continually making inferences or drawing conclusions from given data or premisses: and if the inferences so made were always valid there would be no need for any one to trouble further about the matter. Experience, however, teaches us that nothing is more common than for people to draw conclusions in no way justified by the premisses. Most people at times find their calculations mislead them, which would be impossible were such calculations made validly from true data. Hence it becomes necessary to consider under what conditions we may draw conclusions from given premisses; to find out whether there are general rules which must be observed in reasoning, and if so what

* *Data* is the plural of *datum*, a Latin word meaning *something given*.

such rules are. If such rules can be found, they may be called the *Laws* or *Principles* of Reasoning. A *law* or *principle* is the statement of a general truth.

That there are laws of reasoning is evident. No one doubts the truth of the statement that "things which are identical with the same thing are identical with each other". This is a law which no one hesitates to use as a principle of reasoning. Thus, if I am told that A is identical in height with B, and that C is identical in height with B, I immediately conclude that A and C are of identically the same height. The study of such principles of reasoning is conveniently referred to as the study of *Logic*, and *Logic* may be defined as the "Science of the Principles of Valid Reasoning". *Science* is general systematized knowledge about some subject matter, or the knowledge of those general laws which hold good in any department of nature. If Logic be regarded merely as a means to enable us to reason correctly it is then more accurately defined as the "Art of Valid Reasoning". Art is the skilful application of scientific knowledge.

In the next chapter we shall consider various examples of Reasoning.

Résumé of Chapter I.

1. All allow the importance of knowledge.
2. All knowledge is ultimately derived from the senses.
3. Much of our knowledge is directly due to the Reasoning Faculty which elaborates the elements supplied by the senses into more complex knowledge.
4. Truths used to establish other truths are called data or premisses.

5. A truth inferred from others is called a conclusion.
6. Reasoning is the process by which the human mind infers truth from other truths.
7. A Law is the statement of a general truth.
8. The "Principles of Reasoning" are the laws that must be observed in reasoning if our inferences are to be trustworthy.
9. These general principles are the subject matter of the Science of Logic.

Questions on Chapter I.

1. Why have the senses been called the "Portals of Knowledge"?
2. What is Reasoning?
3. By what possible means can the mind acquire knowledge?
4. Explain *data* or *premisses*, and *conclusion*.
5. Point out the premisses and conclusion in the following:—

   All planets go round the sun in elliptic orbits;
   Therefore the earth goes round the sun in an elliptic orbit, for the earth is a planet.
6. What is meant by the "Principles of Reasoning"?

CHAPTER II.

Examples of Reasoning.

The following examples should make the student more clearly understand what is meant by reasoning and, at the same time, enable him to distinguish the different kinds of reasoning treated of in this book.

I.

1. If we know that the statements—

All coins are useful things,

and This shilling is a coin,

are true, can we from these as premisses infer the truth of a third statement different from either of these? Clearly we can.

This shilling is a useful thing,

is such a statement, which is certainly true if the preceding premisses are true and which is therefore a conclusion inferred from those premisses. This conclusion is a truth quite different from either premiss, although, of course, it is contained in the two premisses together. Here we have, then, obtained a fresh truth from known truths, that is, we have reasoned. Moreover, the reasoning is valid, for, granted the premisses are true, the conclusion is also certainly true. The reasoning in this example seems so simple that the student may be inclined to ask how there

can be any difficulty in such a process as this. Let him have patience and he will soon discover that to reach a valid conclusion is often by no means an easy matter.

2. Next consider the premisses—

All fish live in water,
All herrings are fish.

From these we can by a process of reasoning make the inference that

All herrings live in water.

This is, as clearly as in the first example, a valid conclusion.

3. Again, let the premisses be—

All quadrupeds are herbivorous ;
All tigers are quadrupeds.

From these we may apparently infer that

All tigers are herbivorous,

a conclusion which is not true, for tigers are carnivorous.

When the student can apply the rules for testing arguments, to be enunciated hereafter, he will find that the above violates none of such rules, and is therefore valid. If a conclusion is not true there must be something wrong either with the premisses or with the reasoning. These are the only possible sources of the error. If either of the premisses be false the conclusion may also be false and yet be valid. If we examine the premisses in the above argument we easily see that one of them, viz.—

All quadrupeds are herbivorous,

is false. Here, then, is the explanation of the falsity of the conclusion. The fault is not in the reasoning, but in the information given as premisses, and, therefore, such fault is no concern of the mere logician ; he is concerned only with the reasoning, and that is valid.

4. Consider one example more—

All coins are useful things,
All shillings are useful things,
therefore,
All shillings are coins.

The student may at first think this conclusion as valid as any of the preceding ; a little further thought will, however, convince him that it is invalid. There are many useful things which are not coins, and it may be, so far as we can tell from the premisses, that all shillings are among these useful things which are not coins. If instead of—

All shillings are useful things,

we take as our second premiss—

All pens are useful things,

then by the same argument we have as conclusion—

All pens are coins,

which is manifestly untrue ; and as both premisses are true, it must be that something is wrong with the reasoning, and the conclusion is invalid. But if this is invalid so is the previous conclusion, "All shillings are coins," for it is drawn from similar premisses in identically the same way. In treating of the rules of the syllogism we shall again recur to these or similar examples. The fact that we may draw a conclusion which is really invalid, although true and apparently valid, shows the need of rules by which such arguments may be tested.

Two things should be noticed with regard to all the above examples of reasoning.

1. The conclusion is drawn from two premisses.
2. One premiss in each case is a more general statement than the conclusion.

Thus, in Example 4 one premiss is a statement about *all coins*, and is, therefore, more general than the conclusion,

which is a narrower statement made of *all shillings*. The student should pay special attention to these two characteristics of the above arguments, as they are the two distinguishing marks of all *deductive reasoning*.

II.

Now consider another type of reasoning—

1. We gradually find out by observation such facts as the following :—

An apple tends to fall to the ground,
An orange does the same,
A book does the same,
&c., &c.,

And ultimately we draw the conclusion that

All bodies tend to fall to the ground.

That this is an inference is clear, for we certainly have not proved it by experience in every case. It applies to all bodies in all places and at all times—even to the future.

Whether such an inference is valid or not, it is often a matter of great difficulty to decide. Some of the later chapters of this book will be devoted to this form of reasoning, but in an elementary book like this it will be impossible to treat of it fully. We are constantly drawing such conclusions, and frequently they are invalid.

2. Thus, we meet a foreigner and find him hasty; we meet another who is also hasty; and we become acquainted with another of a similar disposition, and we begin to think that

All foreigners are hasty.

Such conclusion is, however, by no means validly drawn from our premisses. Consider another case of an invalid

inference in reasoning of this form. A foreigner in learning English is told

that *tough* is pronounced *tuff*,
that *rough* is pronounced *ruff*, and
that *sough* is pronounced *suff*,

and he straightway calls *dough duff*, having inferred that *ough* always has the sound *uff*.

Two things should be noticed about the examples of reasoning in II.

1. The conclusion is drawn from an indefinite number of premisses.
2. The conclusion is more general than the premisses.

These are the characteristic features of *inductive reasoning*.

III.

We have seen that in deductive reasoning the conclusion is drawn from two premisses and in inductive reasoning from an indefinite number of premisses; now suppose we have but one premiss given, as for instance,

All birds are bipeds,

can we make any inference from this? Clearly we can, for if

All birds are bipeds,

It is evidently true that

1. Some birds are bipeds, and
2. Some bipeds are birds.

And some readers may at first think that

3. All bipeds are birds,

is also a valid inference from the given premiss. It is, however, invalid, as will be fully shown later on.

When conclusions are drawn from a single premiss, as in III., 1, 2, 3, the process is known as *Immediate Inference*. Reasoning, *deductive*, *inductive*, and *immediate* are the forms of reasoning treated of in this book.

Résumé of Chapter II.

I. In *deductive reasoning* the conclusion
   1. Is drawn from two premisses, and
   2. Is less general than the premisses.

II. In *inductive reasoning* the conclusion
   1. Is drawn from an indefinite number of premisses.
   2. Is more general than the premisses.

III. In *immediate inference* the conclusion is drawn from one premiss.

Exercises on Chapter II.

1. Give three examples of valid deductive inference.
2. Refer the following to whichever of the three types of reasoning it belongs:—

   All planets go round the sun in elliptic orbits,

   The earth goes round the sun in an elliptic orbit,

   Therefore the earth is a planet.
3. Is the argument in Question 2 a valid one?
4. Give two original examples of inductive reasoning.
5. When is reasoning said to be immediate?
6. What inferences can be made from—

   All owls are birds?

CHAPTER III.

The Uses of Logic.

From the examples given in Chapter II., it is clear that in certain cases there is great danger of drawing conclusions which are not justified by the given premisses. How can such invalid conclusions be avoided? Whatever will give a clearer understanding of the processes and fundamental principles of valid reasoning will evidently be of great service in preventing and in detecting invalid reasoning, But Logic is the science of the principles of reasoning, hence one great and apparent use of Logic is that it points out what mistakes are of frequent occurrence in reasoning, and how to avoid them. The student should, however, guard himself against expecting too much from a knowledge of Logic. It is quite possible to know all the rules of Logic and yet to reason badly, and on the other hand, it is true that many people reason well who have never studied reasoning as a science.

The practised logician owes his ability to detect error in reasoning not so much to the rules of Logic as he does to the critical frame of mind which has been developed in him by the process of acquiring a knowledge of those rules. He is not so ready to take statements and conclusions for granted as are those who lack such a course of training; he is apt to look upon them with suspicion, and consequently

he detects errors which are passed over by others from lack of careful observation. It is, then, the mental discipline involved in acquiring a knowledge of Logic, rather than the knowledge itself, which gives increased power of reasoning. This mental discipline is, perhaps, the greatest advantage to be derived from the study of Logic. Man is distinguished from animals chiefly by the possession of a mind. The more he cultivates his mind, the farther does he remove himself from the animal state.

The student who subjects himself to the discipline of a course of study in Logic will enlarge his reasoning power and will thus enable himself to make greater and more rapid progress in any branch of study.

The relation between Logic and the different branches of science is an intimate one, for every branch of science consists in collecting facts, or observing phenomena, and making inferences from them; and, as we have already seen, inference is the subject matter of Logic.

A science is for the most part the practical application of Logic to some subject matter. Thus Geology is Logic applied to the study of the earth; Biology is Logic applied to the study of life, and so on. It is worth noticing that *-logy*, which is the termination of the names of so many sciences, is derived from the Greek word *logos* (discourse), the adjectival form of which, *logikos*, gives us our word *Logic*. It is because no science can be studied without the application of Logic that this latter has been called the "Science of Sciences".

For teachers a knowledge of Logic is of special importance. It is characteristic of modern ideas to regard education as consisting in mental training rather than in the mere imparting of information. The phase of mind

which most directly concerns the teacher is the intellect, the highest activity of which is reasoning. Hence, the most important part of mental training is the training of the reasoning power. It is clear, then, that the more the teacher knows about the laws of reasoning the better will he be able to train children to reason. In the words of Herbert Spencer:—"Grant that the phenomena of intelligence conform to laws; grant that the evolution of intelligence in a child conforms to laws; and it follows inevitably that education cannot be rightly guided without a knowledge of these laws".

Nothing is more productive of faults in reasoning than a loose and inaccurate use of words. The student may readily enough allow this, but, at the same time, think the remark does not apply to him. The number of people who are never misled by a wrong use of words is a very small one indeed. Now, one of the most important parts of Logic is that relating to words and the ambiguities to which they are liable; and no earnest student can study this subject without becoming in consequence more careful to use words in their exact meanings, and such care must re-act on his pupils, causing them to use more correct language and consequently to reason more accurately. Moreover, this is not a mere unconscious re-action. The teacher who has had his eyes opened to the dangers that lurk in words will constantly endeavour to enable his classes to avoid such dangers.

Résumé of Chapter III.

THE USES OF LOGIC.

1. To avoid error in one's own reasoning.
2. To detect it in the reasoning of others.
3. As a means of mental discipline.
4. It is especially useful to teachers, for
   a. It tends to make them use words in their exact meanings, and train their pupils to do likewise.
   b. As being the Science of the Principles of Reasoning a knowledge of it gives teachers great help in developing the reasoning power in their pupils.

Exercises on Chapter III.

1. What is the greatest use to be derived from the study of Logic? Why?
2. Why should teachers especially have a knowledge of Logic?
3. Give the derivation of the word Logic.
4. Why has Logic been called the Science of Sciences?

CHAPTER IV.

The Parts of a Deductive Argument.

Before proceeding further it is advisable to examine more fully than was done in Chapter II. an example of deductive reasoning. Every such argument is a complex whole, consisting of certain essential elements. Before the validity of a deductive argument, then, can be tested, it is necessary to understand clearly what these essential elements are, so as to be able without hesitation to analyse the argument into its elements. Having found out what these elements are, it will be necessary to affix a name to each of them. Every art and every science has a language of its own, which it is essential that the learner should know, and Logic is no exception to this rule. It has its own technical terms, with which every student of the subject must make himself familiar. These technical terms are neither numerous nor difficult to learn. A few of them will be elucidated in this chapter.

As an example of the simplest form of the expression of a complete act of deductive thought, consider the argument—

All poets are philosophers,
Tennyson is a poet,
Therefore
Tennyson is a philosopher.

We have here three statements, or *propositions* in the language of Logic, which together form what is called a *syllogism*. This is the English form of the Greek word *syllogismos*, which means a *reckoning all together*. In Logic a syllogism may be regarded as the name applied to the expression of that form of mental activity in which three truths are brought together in one act of thought. A more technical definition will be given later on.

The syllogism is, then, a complex whole consisting of three propositions. Hence, to understand the syllogism the student must first clearly understand the nature of propositions. Now, in the above syllogism, the first two propositions are made use of to establish the truth of the third, and are therefore (as we have seen in Chapter I.), called the *premisses*.

The proposition—

Tennyson is a philosopher,

inferred from the other two, is called the *conclusion*.

The student should carefully notice that although the conclusion is, according to strict logical sequence, the third proposition of the syllogism, yet not infrequently it stands first, as for instance—

Brown is a man (conclusion)

For All heroes are men,
And Brown is a hero, } (premisses)

Sometimes the conclusion occupies the second place in the syllogism, as—

All heroes are men—(first premiss)
Therefore Brown is a man—(conclusion)
For Brown is a hero—(second premiss)

Now we will consider more closely one of the propositions of our typical syllogism. If we examine the proposition—

Tennyson is a poet

we see that it is a complex whole consisting of three elements, namely two names ("Tennyson" and "a poet") and a verb connecting them. The names are called *terms* and the verb which connects them, with or without a negative particle, is called the *copula*. The first term in a proposition when in logical form is called the *subject*, being the name of that which forms for the moment the subject matter of the mind's thought; the second term is the *predicate*, being the name of something predicated of, or asserted to belong to, the subject.

The student must carefully note the difference between the *logical* and the *grammatical* use of the word predicate. The grammatical predicate of the above proposition is—*is a poet;* but in Logic *is* is a copula and forms no part of the predicate. The copula, in every proposition which is expressed in strict logical form, is some part of the present tense of the verb to be.

The student will notice that although each proposition of the above syllogism contains two terms, yet there are but three terms altogether, as each occurs twice. This is the case in every valid syllogism.

From the above analysis it is clear that a knowledge of terms is necessary to the proper understanding of propositions, and a knowledge of propositions to the understanding of the syllogism. Hence, in text books of Logic, terms and propositions are treated of before the syllogism.

As in every syllogism there are three terms, two only of which are contained in the conclusion, there will always be one term which does not occur in the conclusion. This is called the *middle term.* In the syllogism considered above the three terms are *poets, philosophers, Tennyson;* of these *poets* does not occur in the conclusion and is therefore the

middle term. The other two terms have also appropriate technical names. The subject of the conclusion is called the *minor term*, and the predicate of the conclusion is the *major term*. The reason for calling these terms by these names will be made clear later on.

If, then, the symbols S, M, P stand for the minor, middle, and major terms respectively, the syllogism can be represented in the form—

All M's are P,
All S's are M,

Therefore

All S's are P.

The symbols S, M, and P are used as being the initials of *subject* (of conclusion), *middle term*, and *predicate* (of conclusion). This method of representing syllogisms is frequently of use in testing their validity.

Terms, propositions, and syllogisms are properly applied to the language in which thought is expressed, and not to thought itself. It is useful to note what mental operations correspond to these parts of the language of thought.

The process by which the mind gains simple ideas, or ideas of individual objects, is called *perception* ; and the process by which it gains general ideas, or ideas of classes, is known as *conception*. A simple idea is a *percept* and a general idea is a *concept*. A term is the name of a percept or of a concept. Hence, terms may be regarded as corresponding to the mental processes of *perception* and *conception*. When the mind compares two ideas and decides whether or not such ideas agree it is said to *judge* ; the resulting product is a *judgment*, and the expression of this in words is a *proposition*, which is, therefore, the logical term corresponding to the mental operation of *judging*.

Finally, reasoning is the process by which one truth is inferred from others, the expression of such complete mental act being a syllogism whenever the reasoning is *deductive*. Hence we see that term, proposition, syllogism, are logical words corresponding to the psychological words perception and conception, judging, reasoning, respectively.

Résumé of Chapter IV.

I. Definitions.

1. A *term* is the name of an idea.
2. A *proposition* consists of two terms and a copula.
3. A *syllogism* consists of three propositions, two being premisses and one conclusion.

II. Terms in a syllogism.

a. The *Minor* term is the subject of the conclusion denoted by the symbol S.

b. The *Middle* term is the term which does not occur in the conclusion, denoted by the symbol M.

c. The *Major* term is the predicate of the conclusion, denoted by the symbol P.

III. Psychological words corresponding to term, proposition, syllogism.

1. *Perception* and *conception* supply ideas, the names of which are *terms*.
2. *Judging* results in a *judgment*, the *expression* of which is a *proposition*.
3. The expression of a complete act of deductive reasoning is a *syllogism*.

Exercises on Chapter IV.

1. Point out the *terms* and *propositions*, distinguishing premisses from conclusion in :—
   a. Socrates is mortal, for Socrates is a man, and all men are mortal.
   b. Diligent students pass their examinations, therefore A B will pass his examination, for he is a diligent student.
   c. S is P, for S is M and M is P.
2. What is the connection between terms and conception?
3. Why do text books of Logic treat of terms before propositions and of propositions before syllogisms?
4. Which is the middle term in the following syllogisms?
   a. All flowers are beautiful : therefore the rose is beautiful, for it is a flower.
   b. Logic is useful, for all science is useful, and Logic is a science.
   c. All coins are useful,
   A shilling is a coin, therefore
   a shilling is useful.
5. Give three original examples of valid syllogisms.

CHAPTER V.

The Laws of Thought.

Before proceeding to treat of terms it will be well to consider somewhat more fully the Laws of Thought referred to in Chapter I. Underlying all valid reasoning there are certain general principles or laws which are usually referred to as "the fundamental laws of thought." They are "laws" of thought, for it is in accordance with them that all valid thought proceeds; and they are fundamental laws, for they are incapable of being derived from other simpler laws.

The fundamental Laws of Thought are three in number:—

1. The Law of Identity, *viz.*, Everything is what it is, or, A is A.
2. The Law of Contradiction, *viz.*, Nothing can both be and not be, or, A cannot both be B and not be B.
3. The Law of Excluded Middle, *viz.*, Everything must either be or not be, or, A either is or is not B.

These laws are the simplest possible expression of the principles underlying valid thought. They are so simple as to be incapable of proof (though of course they may be

illustrated) and as to make the discussion of them seem altogether unnecessary or possibly childish; and they are severally independent, that is, they are all individually incapable of being derived from the others. This must be the case, since each is a fundamental law.

The truth of the first of these laws is perfectly evident, and yet in practice it is constantly being violated. Every time that the same term in the *same* argument is allowed to have two meanings, the Law of Identity is violated. Later on we shall see how frequently this is the case. The student should further notice that this law not only includes such cases as A is A, where the identity is complete, but also such cases as A is B, where the identity is only partial, the identity existing amidst diversity. If we say apples are fruit, we do not mean that apples are identical with fruit, but that some of the qualities of apples are identical with some of the qualities of fruit.

The Law of Contradiction may, at first, appear less evident. It denies that anything can, *at the same time and same place*, both possess an attribute and not possess it, or, which is the same thing, that a statement can be both true and not true at the same time. The paper of this book may be partly white and partly not white (black); but in the same place it cannot both be white and not be white. It is inconceivable that of two contradictories both should be true. Immediate Inferences (see Chapters X., XI.) from affirmative propositions may be shown to depend, for their validity, on the Laws of Identity and of Contradiction. As the Law of Contradiction guards against the admission of two contradictories as true, that is, it preserves the condition of non-contradiction in argument, it would be better called the Law of Non-contradiction.

The Law of Excluded Middle is the least evident of the three laws. Some writers have even thought it untrue, but such thought has arisen from a misconception of its meaning. It has not been sufficiently noticed that the law is concerning *contradictories* and makes no assertion whatever about *contraries*. It asserts that A is or is not B; it does not assert that A is B or is the contrary of B. It is quite true that a piece of iron may be neither hot nor cold; but cold is the *contrary* and not the *contradictory* of hot, the true contradictory being not-hot, and it is inconceivable that a piece of iron, or anything else, should be neither hot nor not-hot—it must be one or the other.

Can we, in accordance with this law, assert that *honesty is, or is not, triangular?* Perhaps the simplest answer to this question is to be found in the fact that the Law of Excluded Middle is a law of *thought*, and has nothing to do with the meaningless, and such an assertion as the above is meaningless. But if we assert that honesty is not triangular are we necessarily to be taken to mean that honesty is not three-sided, but is of some other shape? Not necessarily so. Honesty has no shape at all and cannot therefore be triangular. Even in this case, then, the law holds good. The law has received the somewhat curious name of "excluded middle" from the fact that it asserts that any statement must either be true or not true, thus denying the possibility of the existence of a *middle course*—the possible existence of a middle course is excluded by the law.

These three laws are sometimes spoken of as the *necessary* Laws of Thought, because any one who thinks correctly, of necessity thinks in accordance with them.

The above are the only *fundamental* Laws of Thought; there is, however, another law of great importance, which

was first enunciated by Leibnitz and which is generally referred to as the "Law of Sufficient Reason." It may be stated thus:—"Nothing happens without a sufficient reason why it happens as it does, rather than otherwise." This, however, is not a law by which our thinking is regulated, but rather an assertion that thought is possible concerning any and every phenomenon. There are certain other principles, deducible from the fundamental Laws of Thought, which logicians have enunciated and have regarded as important because logical arguments can be tested by them more easily than by the fundamental Laws of Thought. They are usually spoken of as Canons or Axioms.

A *Canon* is a *rule*, and an *Axiom* is a statement which is so simple that it cannot be proved by reference to simpler statements, and which is, as soon as understood, necessarily regarded as true.

These canons are :—

1. "If two terms agree with one and the same third term, they agree with each other."
2. "If one term agrees and another disagrees with the same third term, these two disagree with each other."

Sometimes another canon is given, viz.,

3. "Two terms, both disagreeing with the same third term, may or may not agree with each other."

The student should compare Euclid's first axiom with the first of these canons. As an illustration of the first, consider the three terms *iridium*, *heaviest metal*, *rarest metal*. If *iridium* and *heaviest metal* both agree with the term *rarest metal*, then *iridium* and *heaviest metal* agree with

each other, or *iridium is the heaviest metal.* Symbolically, if A agrees with B, and C agrees with B, then A agrees with C.

As an illustration of the second canon, consider the terms *London*, *Metropolis*, *Cambridge.* The term *London* does, and the term *Cambridge* does not, agree with the same third term *Metropolis*, therefore they do not agree with each other, or, *London is not Cambridge.*

Again, consider the terms *ivory*, *elephants' tusks*, and *bone.* In this case the terms *ivory* and *elephants' tusks* both disagree with the term *bone*, and they do agree with each other, for *elephants' tusks* are *ivory;* but in the case of the terms, *Ely*, *Metropolis*, *Cambridge*, the first and third disagree with the second and they disagree with each other, for Ely is not Cambridge.

There is still one other rule in Logic that should be mentioned here, viz., Aristotle's *dictum de omni et nullo* (statement concerning all and none). The simplest form of this is:—"Whatever may be predicated distributively of a class may be predicated of every individual in that class, and whatever may be denied distributively of the class may be denied of every individual in it." The first part of this is the *dictum de omni* or *statement concerning all*, and the second part is the *dictum de nullo*, or *statement concerning none.* Thus, we may predicate of the class *material things* that they have weight, therefore the *dictum* says we may predicate of wood that it has weight, for it is part of the class *material things;* and of the class *material things* we may deny that they can reason, therefore we may deny of a *stone*, which is a *material thing*, that it can reason.

Résumé of Chapter V.

I. The fundamental Laws of Thought are —
   1. Law of Identity. Everything is what it is.
   2. Law of Contradiction. Nothing can both be and not be.
   3. Law of Excluded Middle. Everything must either be or not be.

II. The Law of Sufficient Reason is: — "Nothing happens without a sufficient reason why it happens so rather than otherwise."

III. Logical Canons.
   1. If two terms agree with one and the same third term, they agree with each other.
   2. If one term agrees and another does not agree with the same third term, these terms do not agree with each other.
   3. Two terms, both disagreeing with the same third term, may or may not agree with each other.

IV. Aristotle's *dictum de omni et nullo* is:—"Whatever may be predicated distributively of a class may be predicated of every individual in that class; and whatever may be denied distributively of a class may be denied of every individual in that class."

Exercises on Chapter V.

1. What is a law?
2. What is a fundamental law?
3. Enunciate and illustrate the Law of Contradiction.
4. Enunciate and illustrate the Law of Excluded Middle.

5. It has been said :—"A door may be neither open nor shut, but ajar, therefore the Law of Excluded Middle does not hold." Answer this objection.
6. Explain *canon* and *axiom*, giving examples.
7. Show, by using Aristotle's dictum, that the conclusion *Apples are useful* follows from the premisses, *apples are fruit*, and *all fruit is useful*.
8. Illustrate the first of the three logical canons.

CHAPTER VI.

Terms.

In Chapter IV. we saw that a proposition consists of two names or terms and a copula. In this and the following chapter we proceed to examine terms more closely.

The philosopher Hobbes, nearly two hundred and fifty years ago, defined a name or term in these words :—"A name is a word taken at pleasure to serve for a mark which may raise in our minds a thought like to some thought we had before, and which, being pronounced to others, may be to them a sign of what thought the speaker had or had not before in his mind." The words "or had not" may be omitted without injuring the definition. Hobbes introduced them in order to make the definition embrace the names of negative ideas, an explanation of which will be given shortly.

Note carefully the two purposes served by terms :—

1. As *marks* to recall ideas (for that is what Hobbes means by "thoughts") which we have had previously in mind.
2. As *signs* to others of the ideas we have in mind.

The word *term* is merely a curtailed form of the Latin word *terminus*, an end, and was applied to the names of a proposition, because such names form the *ends* of the proposition. Strictly speaking, names are *terms* only when

they occur in propositions. Generally, however, all names are called terms, as being able to constitute the ends of propositions. A term may consist of any number of words. Thus in the proposition, "*Victoria, Queen of England, Ireland, Scotland and Wales, and Empress of India*, resides at Windsor," the twelve words in italics, constituting the subject of the proposition, form but one term. Clearly all words cannot stand alone as terms. We cannot say, "Very is honest". Words that can stand alone as terms are called *categorematic* ; words that cannot, *syncategorematic.* If, however, a syncategorematic word be itself regarded as a thing, it can stand alone as a term. Thus we can say "Very is an adverb" meaning the word "very" is an adverb. This looking upon a word as a thing is known as *Suppositio materialis.*

Adjectives are to be classed as categorematic words, for in such a proposition as, *the day is warm*, *warm* is a term.

Since terms may consist of any number of words, they may be arranged in two classes.

1. Single-worded terms.
2. Many-worded terms.

A *single-worded term* consists of one word only, which must of course be a categorematic word. Thus, the terms in a proposition such as—

Coal is useful,

are single-worded terms.

A *many-worded term* is one consisting of more than one word, as, for instance, *the angles at the base of an isosceles triangle.*

Again terms are :—

1. Individual or Singular, and
2. General.

An *individual* or *singular* term is a name applicable in the same sense to only one thing, as *the Queen*, *my house*. Those names which in Grammar are known as proper nouns are logically individual terms, for though such a term as John may be applied to many different persons, yet when used it always refers definitely to one and it is incapable of being applied in the *same sense* to another. In the proposition—

He is quite a Milton,

the term Milton is the name of a class, as is clear from the fact that the article *a* goes with it ; it is a *general* term and grammatically a common noun.

A *general term* is one that can be applied in the *same sense* to an indefinite number of things. Thus *pen* is a general term, for it is applicable in the same sense to an indefinite number of objects, all of which have certain common qualities which constitute the meaning of the term *pen*. Since these objects possess certain common qualities, we may regard them as forming a class which contains every object possessing these qualities. The name of this class is a general term, and every general term is a class name.

A general term is, from the psychological point of view, the name of a concept, which has been already defined as a general idea (see Chapter IV.). The above division of terms into the two classes of *individual* and *general* terms is exhaustive, that is, every term must belong to one or other of these classes. Both individual and general terms may be used in a *collective* sense, that is, as the name of a number of things regarded as forming one whole ; when so used they are often called *collective terms*.

The collective use of *individual* terms is not of frequent occurrence. The *British Army*, *the Andes*, the *English*

Nobility, are examples. General terms are of much more frequent occurrence as collective terms ; thus, *crowd*, *army*, *nation*, *mob*, *fleet*, etc., are examples of words that may be used as collective terms. The student should carefully note that it is impossible to say of any given term, such as *forest*, whether or not it is collective. It depends entirely on its use. Thus, if the word *forest* is used to denote a number of trees it is a collective term, but if used to mean *one of a number of forests* it is a general term. The collective term being the name of a number of objects, regarded as one, cannot be applied to the objects individually, but collectively only ; on the other hand, the general term can be applied individually to the objects constituting the class of which it is the name.

Another division of terms is into

1. Concrete, and
2. Abstract

} terms.

A *concrete term* is the name of a thing, an *abstract term* is the name of an attribute of a thing, considered apart from the thing to which such attribute belongs. The word *thing*, it should be noticed, is used in its widest possible sense to denote every possible notion except those of attributes. There are non-material as well as material things. Thus, *mind*, *thought*, *will*, *ghost*, are names of things, although they are not material. The process by which the mind withdraws or abstracts its attention from all other qualities and fixes it on a certain one is called *abstraction*. The name of such quality contemplated by abstraction is an abstract term.

Thus, we talk of *honest people*. If we think of the quality from the possession of which they are called *honest*, and apply a name to it we have the abstract term

honesty. Adjectives are *concrete* terms, not *abstract*, for they always express some quality as belonging to an object and not considered as apart from such object; thus in the proposition "iron is heavy" it is not meant that iron is the quality denoted by the word heavy, but that it is a thing possessing such a quality; so again the proposition "Great is Diana of the Ephesians" does not mean that Diana of the Ephesians is the *quality* greatness, but that Diana is a great being or great goddess. Logically there is no distinction in kind between the term "great" in "Diana is great" and the term "goddess" in "Diana is a goddess". To every concrete term there is, or may be, a corresponding abstract term; thus *soapiness*, *inkiness*, *sweetness*, *nakedness*, are the abstract terms corresponding respectively to the concrete terms *soap*, *ink*, *sweet*, *naked*. Whether the abstract corresponding to a given concrete term exists in English or not is a mere accident of our language. If the need of the abstract has been frequently felt, someone is sure to have invented it and others to have used it; but if the need has never, or only occasionally, been felt, the corresponding abstract does not exist. Thus *orange*, *apple*, *potato*, *book*, *window*, are concrete terms to which corresponding abstract terms are not to be found in our dictionaries.

It is a fact deserving notice that an abstract term frequently, in course of time, becomes concrete. This arises from the difficulty of abstraction to the uneducated mind. Thus, *relation*, which properly denotes *the connection between relatives*, is frequently used concretely for *relative*; thus, we talk of our *friends and relations*, meaning *friends and relatives*.

To what a large extent this change of abstract to concrete terms has been carried on may be seen by noticing the

present meaning of terms whose endings indicate that originally they were abstract. It will be found that many, perhaps the majority, of such terms are now used as concrete general terms. Thus all words ending in -tion, -sion, were originally abstract; but now such words as benediction, proposition, proportion, addition, nation, and dozens of others, are generally used as concrete terms.

Another way of dividing terms is into the two classes—

1. Positive.
2. Negative.

A *positive term* is one which signifies the presence of some one or more qualities. In accordance with the Law of Excluded Middle, everything in the universe must either belong or not belong to the class denoted by any name. Thus, let the name be metal, then everything is, or is not, metal. If we frame a word to denote everything that is not metal (*non-metal*, say) then *metal* is a positive and *non-metal* the corresponding negative term. In many cases it is difficult to say which is the positive and which the negative term, and frequently it is a matter of little or no importance which is called positive, so long as the other is called negative.

The student will notice that certain prefixes are indicative of the absence of a quality, that is, of a negative term; such prefixes, for example, as *un-*, *in-*, *dis-*, *non-*, are of this nature. The form of a word is, however, often misleading; thus in form *inconvenient* is a negative term, but it seldom, if ever, denotes the mere absence of convenience, but rather implies the presence of actual trouble, and it should, therefore, be regarded as a positive term.

When a negative term implies the absence of a quality which was once present, or which might be expected to be

present, such term is called *privative*, *e.g.*, blind, dead, dumb, etc.

A positive and its corresponding negative are contradictory terms, each being the contradictory of the other. *Contradictory* terms must be carefully distinguished from what are called *contrary terms*. The *contrary* of a term is one denoting what is farthest removed from that term. Contrary terms are often called *opposite* terms. Thus *small* is the contrary or opposite of *great*, the strict contradictory of which is *not-great:* so *not-white* and *black* are the *contradictory* and *contrary* respectively of *white*. This is a distinction of great logical importance, and should, therefore, be carefully remembered.

Still one further way of dividing terms must be here noticed.

Terms are—1. Relative, or
2. Absolute.

A *relative term* is one which, besides denoting an object, implies the existence of another object without reference to which it is unintelligible; thus the term *king* can be understood only by reference to *subject*, and *subject* only by reference to *king*.

An *absolute* or *non-relative* term is one which denotes an object without any direct reference to the existence of another object, as, for instance, *sun*.

It is often impossible to say of a term apart from its context whether it is relative or absolute; thus *man* is a relative term when used in contra-distinction to *woman*, but it is absolute when meaning mankind.

Relative terms evidently go in pairs – as parent, child; king, subject; shepherd, sheep; teacher, pupil; every pair consisting of two *correlative terms*. That which constitutes

the bond or connection between any pair of correlatives is called the *fundamentum relationis*. For instance, the *fundamentum relationis* in the case of the correlatives teacher, pupil, is the *giving of instruction* in the case of the teacher and the *receiving of such instruction* in the case of the pupil. In some cases a pair of correlatives have but one name ; thus, the correlative of *friend* is *friend*, of *foe* is *foe*, of *brother* is *brother*, though it might be *sister*.

Résumé of Chapter VI.

I. Words are—

1. Categorematic,
2. Syncategorematic.

The former can stand alone as terms, the latter cannot.

II. There are several ways of dividing terms, as into

1. *a*. Single-worded terms.
   b. Many-worded terms.

   A single-worded term is a categorematic word.
2. *a*. Individual or singular terms are those applicable to only one thing in the same sense.
   b. General terms are applicable in the same sense to every one of a class of things.
3. *a*. Terms used distributively.
   b. Terms used collectively, namely, when applied to a number of things regarded as one whole.
4. *a*. Concrete, being the names of things.
   b. Abstract, being the names of qualities.

   Adjectives are concrete. Corresponding to any given concrete an abstract may, but does not always, exist.

5. *a*. Positive terms implying the presence of qualities.
   b. Negative terms implying the absence of certain qualities.
   c. Privative terms implying the absence of qualities which might be expected to be present.
6. *a*. Relative terms. A relative term is one which is intelligible only by direct reference to another term.
   b. Absolute terms : An absolute term makes no direct reference to another term.

Exercises on Chapter VI.

In giving the logical characters of terms the student should say whether they are—

1. Single-worded or many-worded.
2. Singular or general.
3. Collective or distributive.
4. Concrete or abstract.
5. Positive, negative or privative.
6. Relative or absolute, *e.g.*—

   The Sun :—Many-worded, singular, concrete, positive, absolute.

   Blind :—Single-worded, general, concrete, privative, absolute. If there is any doubt as to the meaning of a term, it should be stated what such term is understood to mean, and its character given accordingly.

1. Give the logical characters of :—woman, king, school, church, army, honesty, moon, the moon, star, table, relation, relative, good, evil.

2. Explain the difference between contradictory and contrary terms.
3. Is the term *idle*, positive, negative, or privative? Give full reasons for your answer.
4. Give the negative of:—equal, great, London, good, tall, teacher.
5. Explain *fundamentum relationis*.
6. What is a collective term? Is the term *navy* collective?

CHAPTER VII.

Terms—(Continued).

We have now to consider an exceedingly important point with regard to terms, and one that will need the closest attention to be clearly understood.

Examine closely the meaning of any general term, such as *school*. This evidently includes, in its meaning, St. Paul's School, Westminster School, City of London School, and all buildings in the world which are rightly called "schools". All objects, then, which correctly bear the name *school*, are, in one sense, the meaning of the term *school*. They are the extent to which the term is applied, and form, therefore, what is sometimes called the *meaning in extension* of the term *school*. Similarly, every other general term has a meaning in extension, such meaning being all the objects forming the class of which the term is a name. But all general terms will be found to have another meaning. Consider further the term school. Before the term school can be applied to an object, such object must possess certain qualities: it must at least be a building in which teaching is carried on. Every general term is a name applied to all the individual objects constituting a class and any object can belong to such class only in consequence of the possession of those attributes on which the class is based. Hence, these attributes must be possessed by any object

before the class name or general term can be applied to it. The application of a general term to any object clearly, then, conveys certain information about that object, such information being, in one sense, the meaning of the term. This meaning is sometimes called *the meaning in intension*, the term *intension* being used in contra-distinction to *extension*. Thus, the meaning in extension of the term school is the number of things which are rightly called schools, and its meaning in intension is the *qualities* any object must possess before it can rightly be called a school. The meaning in extension is evidently the objects *denoted* by the term, and may, therefore, more conveniently be called the *denotation* of the term ; as a correlative to this, the meaning in intension may be called *connotation*. These terms were first used by Mill, with these meanings. They are convenient, as we have the corresponding verbs to *denote*, and to *connote*, as well as the adjective *connotative*.

Moreover, their meaning is suggested by their etymology ; to denote (Lat. *de*, down, and *noto*, I mark) is to mark down the objects to which the name may be applied, and to *connote* (Lat. *con*, along with, and *noto*, I mark) is to mark the qualities along with the objects.

There is a close connection between the denotation and the connotation of a term. Consider the term *book*. Now to *book* add *English*, so that the term becomes *English book*. Evidently, there are fewer *English books* than *books* in existence, and hence the denotation is decreased. By adding *English*, then, to the term *book* we obtain a new term, viz., *English book*, the denotation of which is less than that of book. The connotation of book is a certain number of qualities, all of which are connoted by the term *English book*, which also connotes the additional quality of

being printed in English. Hence, by adding English to the term book we obtain a new term, viz., *English book*, the connotation of which is greater than that of *book*.

If we make to *English book* an addition expressing another quality we shall still further increase connotation and decrease denotation. Thus, if we add *on logic*, we have the term *English book on logic*, the connotation of which is greater than that of *English book*, and the denotation is less, for clearly there are fewer *English books on logic* than there are *English books*. If the process were continued we should finally obtain a term the connotation of which would be so great that the term could be applied to only one object, which object would form the denotation of the term. *English book on logic which you are reading* is clearly such a term, for the connotation is such that it applies to only one object.

It is clear, from what has just been said, that if the denotation of a term be decreased the connotation will be increased, and that if the denotation be increased, the connotation will be decreased. This is sometimes expressed by saying that the *connotation increases as the denotation decreases*. It must, however, be noticed that the ratios between the connotation and denotation of two terms do not form a mathematical proportion. Thus, we must not suppose that the connotation of *English book* bears the same numerical relation to the connotation of *book* as the denotation of *book* bears to the denotation of *English book*. By a slight increase of connotation the denotation may be very greatly reduced. Thus, if to the term *mountain* we add *of altitude of above 29,000 feet*, the denotation is reduced to a minimum, for the term, *mountain of altitude of above 29,000 feet* denotes one

object only, viz., Mt. Everest. If, however, we add *of altitude of more than 3,000 feet*, the connotation is increased as much as in the previous case, although the denotation is decreased not nearly so much.

Now the question arises whether all terms have connotation or not. This question may be answered by the consideration of an example. If, on seeing a number of buildings in the distance, I ask what place it is, and I am told in reply that it is *Cambridge*, it is evident that such answer gives me no knowledge of the place itself. It tells me that there is a place called Cambridge, but it tells me none of the attributes of such place. I may possibly know that Cambridge is a *town* and *the seat of a University*, in which case, on hearing the term Cambridge, there instantly arises in my mind the fact that it is a town and the seat of a University. But the term *Cambridge* merely *suggests* such information by association of ideas; in no sense can such information be regarded as the *meaning* of the term. But if, in answer to my question, I am told that the place is a *town*, then the word itself does convey real information, viz., whatever is connoted by the term *town*. The term *Cambridge* has no connotation, but the term *town* has connotation. Terms possessing connotation are called *connotative* terms, and those not having connotation *non-connotative* terms. A connotative term denotes a thing and implies one or more attributes. It is clear that all general terms, all adjectives (which are general terms) and collective terms (except proper names, such as the Pyrenees) are connotative. A non-connotative term only denotes a thing or an attribute. All terms which grammatically are called proper nouns, are non-connotative. A proper noun is never the name of a class.

Of course, a proper noun may be used to designate a class, implying that every member of the class possesses the qualities characteristic of that to which such proper noun was first applied, but then in such use it is not a proper noun or individual term, but a class name or general term. In such a sentence as:—"He is quite a Shakespeare," the word Shakespeare is no more a proper noun than is the word poet in the sentence "He is quite a poet".

All *singular abstract terms* denote an attribute only and are, therefore, *non-connotative*. Abstract nouns, however, that can be used in the plural, such as, *colour*, *virtue*, *vice*, are the names of classes, that is, they are general terms and as such have connotation. The student is recommended to make himself thoroughly familiar with the terms denotation and connotation, as a thorough understanding of them is of the highest importance. Though the distinction between them is a perfectly definite and clear one, yet many students seem to find great difficulty in understanding it.

Résumé of Chapter VII.

I. 1. The denotation or meaning in extension of a term is the objects to which the term can be applied.

2. The connotation or meaning in intension is that quality or those qualities which an object must possess in order that such term may be rightly applied to it.

Denotation is *things*: *connotation* is *qualities*.

3. By increasing connotation, denotation is decreased, and by decreasing connotation, denotation is increased.

II. Terms are *connotative* or *non-connotative*.

1. A connotative term denotes a thing and implies one quality or more.
2. A non-connotative term denotes a thing only or an attribute only.
3. General terms, adjectives, and collective terms, are connotative.
4. Proper names and singular abstract terms are non-connotative.

Exercises on Chapter VII.

1. What is the denotation of a term?
2. What is the connotation of a term?
3. Give three examples of connotative and three of non-connotative terms.
4. What is the denotation of :—fish, man, book, servant, bird, table?
5. What is the connotation of :—triangle, line, book, animal?
6. Show that by increasing the connotation of the term *ship* its denotation is decreased.
7. Why have proper names no connotation?
8. Criticise the assertion that the denotation decreases as the connotation increases.

LIBRARY OF THE UNIVERSITY OF CALIFORNIA

CHAPTER VIII.

Propositions.

The student has already from Chapter IV. gained some idea of the meaning of the word *proposition*; we proceed to discuss its meaning more fully. Consider the pair of terms —*sugar, sweet.* Do they agree? If so, we may say *sugar is sweet.* Do they not agree? If they do not we may say *sugar is not sweet.* So of the terms *silver, tenacious.* If we think they agree, we say *silver is tenacious*; but if we decide that they do not agree, we say *silver is not tenacious.* So again of the terms *gold, malleable.* We first decide as to whether or not they agree, and then we make the statement *gold is malleable* or *gold is not malleable.* What we decide in every such case is whether or not our ideas of the meanings of the two terms agree; and to express such decision we make use of what is called a *proposition.* A proposition may be defined, then, as *the assertion or the denial of agreement between two terms.*

A general term is, as already stated (Chapter VI.), the name of a *concept.* Thus, the term *tree* is to me a name of whatever is in my mind when I think of tree in general without special reference to any particular tree, that is, it is the name of my *concept* of tree.

The mental process by which we decide whether or not one concept may be regarded as connected with another

concept is what the psychologist means by *judging*, and the result of such process is a *judgment*, the verbal expression of which is a proposition. A proposition may, in fact, be defined as *the expression of a judgment*. The student will easily see that this definition is in reality the same as that given above, where a proposition is defined as the assertion or denial of agreement between two terms. It is clear, then, that every proposition is a sentence ; it is not true, however, that every sentence is a proposition. Those sentences only which unconditionally or conditionally assert facts are propositions.

Hence—

Mere exclamatory sentences
Interrogative sentences
Imperative sentences
} are not propositions.

None of these express *thought*, which is the subject matter of Logic.

It has already (Chapter IV.) been pointed out that every proposition consists of two terms connected by a copula, which copula is always the *present* tense of the verb *to be*, affirmative or negative, and all sentences should be reduced to this form before attempting to apply any of the rules of Logic to them. Thus, the sentence, *Familiarity breeds contempt*, in the strict form of a logical proposition is, *familiarity is a thing which breeds contempt*, in which *familiarity* is the subject, *is* the copula, and *a thing which breeds contempt* the predicate. So the logical form of *birds fly* is *birds are things which fly*, the terms being, *birds* and *things which fly*. In Logic, it is always allowable to change the wording of a proposition, provided the meaning is not changed. A most important part of the usefulness of Logic as a means of mental discipline, is that which is involved

in the careful examination of common forms of expression and in the reduction of such to typical logical forms.

Propositions are of three kinds—

1. Categorical.
2. Conditional or hypothetical.
3. Disjunctive.

A proposition is (1) *categorical* when the predicate is simply, directly and unconditionally affirmed or denied of the subject, *e.g., gold is yellow, silver is useful, rain is falling.*

(2). A conditional proposition is one in which the predicate is affirmed or denied of the subject under one or more conditions, *e.g., if this is gold it is yellow; if he works hard he will pass his examination; if the wind is in the east it is cold.*

A proposition is (3) *disjunctive* when it asserts or denies the truth of some one of two or more facts but does not definitely assert or deny the truth of any given one; *e.g., he is either a Spaniard or an Italian; the prisoner will be found guilty or he will be acquitted.*

Nothing further need be said at present on the subject of conditional and disjunctive propositions; we shall, however, discuss them more fully later on. For some time our whole attention will be given to categorical propositions.

Can categorical propositions be classified? The most evident way of classifying them is to arrange them in two classes according to the absence or presence of "not" or its equivalent in the copula. We have then—

I. *Affirmative propositions*, or those in which the copula does not include a negative particle, *e.g., the man is honest.*

II. *Negative propositions*, or those in which the copula does include a negative particle, *e.g., the man is not honest.*

This is a classification according to *quality*. By the Law of Excluded Middle every proposition must be of *affirmative* or of *negative* quality. All propositions that affirm the agreement of two terms are of affirmative quality, and all that deny such agreement are of negative quality.

Propositions may also be arranged in two classes by considering their *quantity*. The *quantity* of propositions depends upon whether the predicate is explicitly affirmed or denied of the whole of the subject or not.

Propositions in which the predicate is affirmed or denied definitely of the whole of the subject are said to be of *universal quantity*, or more shortly, *universal;* propositions in which the predicate is affirmed or denied of some indefinite part of the subject are said to be of *particular quantity*, or more briefly, *particular*. Thus, *All Englishmen are brave* is a universal proposition, because "bravery" is affirmed explicitly of the whole denotation of the subject; but in *some Englishmen are brave*, bravery is only affirmed of some indefinite part of the subject, and the proposition is, therefore, particular. If we combine this classification according to *quantity* with the classification according to *quality*, we shall have four classes of propositions—

I.	Universal.	1. Affirmative.	Symbol	A.
	,,	2. Negative.	,,	E.
II.	Particular.	3. Affirmative.	,,	I.
	,,	4. Negative.	,,	O.

These may be typically represented thus :—

Universal Affirmative,	All S's are P,	A
Universal Negative,	No S's are P,	E
Particular Affirmative,	Some S's are P,	I
Particular Negative,	Some S's are not P,	O

The letters A, E, I, O, are used for the sake of brevity as symbols of the four classes of propositions, respectively, after which they are placed. By an A proposition is meant a *universal affirmative*, by an E proposition a *universal negative*, by an I proposition a *particular affirmative*, and by an O proposition a *particular negative*. These symbols are very convenient and are constantly used in Logic; the student should, therefore, learn them thoroughly at once. As a help to remembering them it may be noticed that A and I, the symbols for affirmative propositions, are the first two vowels in *affirmo*, the Latin word for *I affirm;* and that E and O are the vowels in *nego*, the Latin word for *I deny*.

The four classes of propositions, A, E, I, O, may conveniently be symbolised by SaP, SeP, SiP, SoP, respectively, the vowel of each of these combinations denoting the quality and quantity of the proposition symbolised.

Hence the proposition :—

All S's are P	is represented by	either	A or SaP
No S's are P	,,	,,	E or SeP
Some S's are P	,,	,,	I or SiP
and Some S's are not P	,,	,,	O or SoP

This fourfold classification of propositions is exhaustive, that is, every categorical proposition belongs to one or other of the four classes. It is not, however, always easy to say at once to which class a proposition belongs; thus, in the case of the proposition, *Socrates is mortal*, it is not at once evident whether this is SaP or SiP. In this case and in all similar cases, the predication is made of the whole denotation of the subject, although that denotation extends to but one individual, and, therefore, it must be SaP.

Singular propositions, that is propositions having singular terms for their subjects, are always *universal*.

Some propositions do not by their form enable us to tell whether they are universal or particular, *e.g.*, *metals are heavy*. Such propositions are said to be *indefinite* or *indesignate*. Such propositions must be classified according to the meaning the students think they are intended to express. If the above is intended to mean *all metals are heavy*, it is of course SaP; if not, it is SiP. Until the meaning of indefinite propositions be settled they have no place in Logic.

It is most important to notice that in I and O propositions the *some* is altogether indefinite. Thus, when it is asserted that *some boys are clever*, it must not be taken to mean that some boys are and some are not clever. Cleverness is predicated of *some* boys, an *indefinite some*; of how many such predication is made it is altogether doubtful; it must be of one at least, and it may be of all.

One other way of classifying categorical propositions should be noticed, viz., into the classes *explicative* propositions and *ampliative* propositions. *Explicative* or *essential* propositions merely unfold the meaning of the subject term. They convey no knowledge beyond what is contained in the subject term if such term be understood.

A triangle is a figure bounded by three lines is an *explicative* proposition, as it merely unfolds the meaning of the term *triangle*. All definitions are explicative propositions. All propositions that really supply knowledge besides that contained in the meaning of the subject are called *ampliative* propositions, because they *amplify* or enlarge our knowledge. Thus the proposition, *roses are beautiful*, predicates of roses the quality (beauty), which is no part of the connotation of *rose*, and is therefore an ampliative proposition. This division of propositions is of historical interest rather than of logical importance.

Résumé of Chapter VIII.

I. Propositions.

1. Definition:—A proposition is the assertion or the denial of agreement between two terms; or, A proposition is the expression of a judgment.
2. Kinds of propositions.
   a. *Categorical*, which simply and definitely assert something of the subject.
   b. *Conditional or hypothetical*, which make an assertion under certain conditions.
   c. *Disjunctive*, which affirm that one of two or more alternatives is true.

II. Categorical propositions.

1. The *quality* is determined by the absence or presence of the negative particle.
2. By the *quantity* of a proposition is meant whether it is *universal* or *particular*.
3. The classification of categorical propositions is based on the *quantity* and *quality*.
   a. There are four classes—
      A. Universal affirmative. All S's are P. SaP.
      E. Universal negative. No S's are P. SeP.
      I. Particular affirmative. Some S's are P. SiP.
      O. Particular negative. Some S's are not P. SoP.
   b. *Singular* propositions are classed as *universals*.
   c. Indefinite propositions, while indefinite, do not belong to Logic.
4. "Some" in Logic has an indefinite meaning—one at least, it may be more, even *all*.

III. Categorical propositions may be classed as—

1. *Explicative* propositions, which merely unfold the meaning of the subject; and
2. *Ampliative* propositions, which convey information over and above what is contained in the meaning of the subject term.

Exercises on Chapter VIII.

1. Which of these propositions belong to Logic? Why?
   a. Go thou, and do likewise.
   b. Oh! that I had listened to you!
   c. The greater the knowledge, the greater the modesty.
   d. Shall I see you to-morrow?
   e. Cleanliness is next to godliness.
   f. To thine own self be true.
2. Analyse the following into subject, copula, and predicate.
   a. London is a large city.
   b. Hope springs eternal in the human breast.
   c. A thing of beauty is a joy for ever.
   d. Its loveliness increases.
   e. Great is Diana of the Ephesians.
   f. P struck Q.
3. Classify the following propositions according to quantity and quality, *i.e.*, say whether they are A, E, I or O.
   a. All metals are heavy.
   b. No money is useless.
   c. Some birds do not fly.
   d. Money is useful.
   e. Honesty is the best policy.
   f. London is a large city.
   g. Man is a rational animal.

4. Classify the propositions in question 3 into explicative and ampliative propositions.
5. Explain the meaning of *some* in *some men are rogues*.
6. Why is E written in the form *no S's are P*, and not in the form *all S's are not P?*
7. Express the following in strict logical form, adding the symbol to each:—

a. Men form theories.
b. Women jump to conclusions.
c. Teaching is wearying work.
d. Birds are not quadrupeds.
e. Anglo-Saxon is Old English.
f. Fish swim.
g. Man is mortal.
h. P struck Q.
i. Logic is difficult.
j. Shakespeare is many-sided.
k. It is better late than never.
l. I wish you many happy returns of the day.

CHAPTER IX.

Propositions and Distribution of Terms.

In the last chapter we have seen that a proposition is the assertion or the denial of an agreement between two terms; but terms have connotation and denotation. Is it the connotation or the denotation of the terms in a proposition that is most naturally suggested when the proposition is used? To answer this question is to give the *import* of propositions. The proposition—

Logic is useful

clearly affirms that *utility* is an *attribute* of Logic. The student will have no difficulty in understanding this, as the predicate is an adjective; it is equally true when the predicate is a noun. Thus if we say—

An apple is a fruit,

our meaning is, that whatever *attributes* belong to fruit in general belong to an apple; the predicate, although a noun, is really thought of as an adjective, but the subject of the proposition is regarded as a noun denoting a thing. That the predicate is really thought of as an adjective, even although it is grammatically a noun, may be seen from the fact that frequently the noun may be replaced by an adjective, without any material change of meaning.

Thus we may say—

Men are mortals or *men are mortal.*

Hence, in using a proposition, *things* are suggested to the mind by the subject, and *attributes* by the predicate. Logicians usually express this by saying that the *subject* of a proposition is read in *denotation*, but the predicate in *connotation*. The predicate in any categorical proposition expresses the qualities which we affirm or deny of some or all of the subject. Thus, in *Man is mortal*, the attribute *mortality* is predicated of all included in the class man.

Psychologically, then, the predicate of a proposition is to be regarded as an adjective; it is, however, for logical purposes, often convenient to regard the predicate as a class to which the subject class bears a certain relation, or one of a number of possible relations. This is of course always possible although it is not the most natural way of regarding the predicate of a proposition, as we have just seen. In the A proposition, all S's are P, it is asserted that the attributes which form the connotation of P belong to all the class denoted by S; hence, in such a statement, the whole denotation of S is contemplated, or the assertion is intended to apply to every S. When a term is thus referred to in its whole extent, it is said to be *distributed;* but when the whole denotation of a term is not explicitly referred to, the term is said to be *undistributed.*

The distribution of terms is a matter of some difficulty. The student should give his best attention to everything on the subject in this chapter.

From what is said above it is clear that the subject of an A proposition is *distributed*; in fact, it is because its subject is distributed that it is called *universal.*

We have seen that psychologically the predicate of a proposition is an adjective; for the application and illustration of logical rules, it must, however, be regarded as

a class having denotation as well as connotation. From this point of view, we may consider whether the predicate of a proposition is distributed or not. Is the predicate of SaP distributed? Clearly it is not. In the proposition—

All owls are birds,

the class birds is not referred to in its whole denotation, for there are many birds besides owls. In the proposition—

All boys and girls are children,

the predicate, *children*, as a matter of fact, is used in its whole denotation, for there are no *children* other than *boys and girls*. The question is, however, do we know this fact from the proposition itself? The proposition, clearly, no more tells us that *all children* are referred to than the proposition *all owls are birds* tells us that *all birds* are referred to, and, therefore, the predicate is no more distributed in the one case than in the other.

This may be illustrated by the diagrams which were first used by Euler, a German mathematician and logician. If we regard both subject and predicate as class names we may represent the subject class by one circle, and the predicate class by another.

Thus

may be regarded as a symbol for the whole denotation of the subject, and

as a symbol for the denotation of the predicate.

There are five possible relations between the two classes

and

1. The case in which

is wholly included in

(P) but is not the whole of (P). This case may be represented by 
.

2. The case in which (S) and (P) coincide. The symbol for this is 
.

3. The case in which (S) and (P) partly coincide, part of (S) being outside of (P) and (P) being partly outside of (S). The symbol is 
.

4. The case in which (P) is wholly included in (S) but is not the whole of (S); the symbol is 
; and

5. The case in which (S) is entirely outside of (P); this may be represented thus, (S) (P).

These are the only possible relations between the two classes (S) and (P).

Every proposition, then, affirms some relation between subject and predicate which relation can be represented by some one, or more, of the above five diagrams. Now we are in a position to use these symbols to illustrate the A proposition.

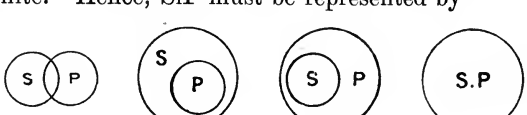
The proposition, *all owls are birds*, may be represented by 
, where S stands for *owls*, and P for birds. This diagram shows at once that there are some P's which are not S's, or some *birds* which are not *owls*.

The proposition, *all boys and girls are children*, may be represented by 
, for subject and predicate in this case coincide. Now, the form of the proposition does not tell us which of these two diagrams should be used to represent it. Hence, to represent SaP fully, we must use both. The universal affirmative proposition then, must be represented by 
In the I proposition, some S's are P, the subject *some S's* is, as we have already seen, quite indefinite, the only thing definitely known of its extent is that it does not explicitly refer to the whole denotation of the class S. Hence, the subject of SiP is *undistributed*. The predicate also clearly is *undistributed*, for when we say *some apples are good to eat*, we certainly do not mean to assert that the only *things good to eat* are *apples*, there being many other edible things to which the predicate makes no reference. The following are all examples of I propositions, and are clearly represented by the diagrams as given to each.

1. Some fruits are edible 
2. Some elements are metals 
3. Some birds are bipeds 
4. Some equilateral triangles are equiangular

It will be noticed that the symbols affixed to 3 and 4 are the same as those used above to represent the A proposition. It is clear that if the relation expressed by SaP is true, the relation expressed by SiP must be true. If *all owls are birds*, it must also be true that *some owls are birds*. We shall return to this point in the following chapter.

Now, the form of the proposition is the same in each of the above four cases. Hence, the form of the proposition does not enable us to say which of the diagrams should be used to represent any given I proposition. This is only the same thing as saying that the meaning of *some* is altogether indefinite. Hence, SiP must be represented by



The first is the most typical symbol and is sometimes used alone, though inaccurately, to represent the I proposition.

In the E proposition, *no S's are P*, the attributes implied in P are denied of *all S's;* hence the subject is distributed.

This proposition may be represented by two separate circles

, representing that no part of the class S is the class P, and clearly showing also that no part of P is in S. Hence, the whole denotation of P is as explicitly referred to as is that of S. The predicate of SeP is, therefore, distributed as well as the subject. Note that only one symbol is needed to represent SeP; the reason of this is that both S and P are definitely referred to in their whole extent, that is, are *distributed.*

In the O proposition, *some S's are not P*, the subject clearly is not explicitly referred to in its whole extent and is, therefore, *not distributed.* That the subject of SiP and SoP is undistributed follows immediately from their definition as particular propositions.

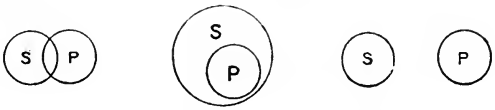
Is the predicate of SoP distributed? This is the most difficult point in connection with the distribution of terms and requires the student's closest attention. In the proposition—

Some elements are not metals,

the subject *some elements* is affirmed to be altogether excluded from the class *metals*; of *all* metals it is denied that any agree with the *some elements* of the subject. Hence the predicate of O is *distributed.*

Owing to the indefinite meaning of the word *some*, it may easily be seen that SoP does not definitely affirm any one of the five possible relations between subject and predicate, but merely affirms that of three of such relations one at least is true. The relations between S and P that the proposition, *some S's are not P*, may include are (3) (4) and (5) as enumerated on page 58.

Hence to represent SoP by Euler's diagrams we must use the three—



The proposition itself always leaves it doubtful as to which of these three diagrams would represent the actual relation between S and P ; this is owing to the indefiniteness of the *some* of the subject. These diagrams make it evident at once that the whole of P is excluded from at least a part of S—another way of seeing that the predicate of SoP is *distributed.*

Collecting the results of our examination of the quantity of the subject and predicate in each of the four classes of propositions, we have—

	Subject.	Predicate.
A or SaP	Distributed	Undistributed
E or SeP	Distributed	Distributed
I or SiP	Undistributed	Undistributed
O or SoP	Undistributed	Distributed

It will be seen at a glance that—

1. Universal propositions distribute their subjects.
2. Particular propositions have undistributed subjects.
3. Affirmative propositions have undistributed predicates.
4. Negative propositions distribute their predicates.

As much of the doctrine of the syllogism depends on the distribution of terms, it is of the greatest importance that the student should make himself thoroughly familiar with the results of this chapter.

The Mnemonic word *Asebinop** may help some students to remember which terms are distributed and which not. In this there are four vowels—A, E, I, and O, which are the symbols of the four classes of categorical propositions.

A is followed by *s*, which stands for *subject*.

E is followed by *b*, which stands for *both* subject and predicate.

I is followed by *n*, which stands for *neither* subject nor predicate.

O is followed by *p*, which stands for *predicate*.

Hence, *Asebinop* may help the student to remember that

A distributes its subject and not its predicate ; that

E distributes both subject and predicate ; that

I distributes neither subject nor predicate ; and that

O distributes its predicate.

Résumé of Chapter IX.

I. In a proposition the *subject* is read in *denotation*, the *predicate* in *connotation*.

II. *Distribution*—

1. A term is *distributed* when explicitly referred to in its whole extent.
2. A term is *undistributed* when the proposition does not make explicit reference to its whole denotation.
3. *a*. SaP distributes its *subject*.
   b. SeP distributes both *subject and predicate*.
   c. SiP distributes *neither subject nor predicate*.
   d. SoP distributes *predicate*.
4. Mnemonic for helping to remember the facts of distribution, AsEbInOp.

---

* Taken from *Picture Logic*, by Alfred Swinburne, M.A.

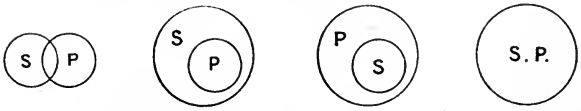
III. Euler's diagrams represent classes by circles.

1. Five possible relations between the two classes

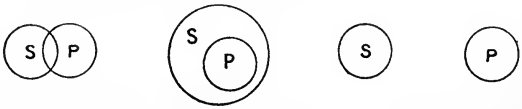
and which are represented thus:—

a. 
b.

c. 
d. 
e. 
2. *a.* SaP is represented by 
b. SeP is represented by 
c. SiP is represented by



d. SoP is represented by



Questions on Chapter IX.

1. Explain the statement—"The subject of a proposition is read in denotation and the predicate in connotation."
2. What is meant by saying a term is *distributed?*
3. Show that negative propositions distribute their predicates.
4. Which terms are distributed in the following propositions. (First see that they are in logical form, then classify as A, E, I, O.)
   a. Some apples are sweet.
   b. Many students are clever.
   c. Nearly all clever and industrious students make good progress.
   d. These be none of Beauty's daughters.
   e. Honesty is the best policy.
   f. Virgil guided Dante.
5. Illustrate by Euler's diagrams all the possible relations between two classes, S and P.
6. Represent by Euler's diagrams :—
   a. Feathers are light.
   b. Glass is transparent.
   c. The penny post is a useful institution.
   d. Not all Englishmen are honest.
   e. Vain pomp and glory of this world, I hate ye.
   f. All that glitters is not gold.
8. Point out any ambiguities in :—
   a. Few birds do not fly.
   b. Every kind of fruit is not edible.
   c. All the angles of a triangle are equal to two right angles.
   d. All is not lost.

CHAPTER X.

Immediate Inference.—Opposition.

We have already seen (Chapter II.) that when a conclusion is drawn from a single premiss, the reasoning or inference is said to be *immediate*. Immediate inference makes explicit what is implicit in a single proposition. It should be at once carefully noticed that it is impossible by any form of immediate inference to evolve from a proposition what such proposition does not contain; immediate inference enables us to make clear what is involved in a given proposition.

There are two kinds of Immediate Inference, viz.—

1. Immediate Inference by *Opposition*; and
2. Immediate Inference by *Eduction*.

In this chapter we shall consider the former of these. *Opposition* is the technical term used to denote the relation existing between any two propositions which have the same subject and predicate but differ in quality, or in quantity, or in both. It should be carefully noticed that this is a somewhat different meaning from that which the word *opposition* has in ordinary discourse. Thus, technically SaP and SiP are *opposed*, though there is no incompatibility between them.

It is clear from the above definition of opposition that any one of the four propositions, SaP, SeP, SiP, SoP, is

opposed to all the others. *Immediate inference by Opposition* is an inference, from a given proposition, as to the truth or falsity of another proposition having the same subject and predicate as the given proposition. Hence the problem to be solved by *opposition* is:—granted the truth or falsity of any one of the propositions SaP, SeP, SiP, SoP, what can we know of the truth or falsity of the rest?

The opposition between
1. A and E is called *contrary*.
2. A and O, or E and I is called *contradictory*.
3. A and I, or E and O is called *subaltern*.
4. I and O is called *sub-contrary*.

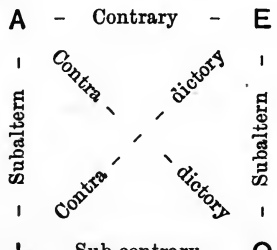
Contrary opposition, then, is the relation between two universals that differ in quality.

Sub-contrary opposition is the relation existing between two particular propositions that differ in quality.

Subaltern opposition is the relation between two propositions that differ in quantity only.

Contradictory opposition is the relation between two propositions that differ both in quality and quantity.

These various kinds of opposition can be most easily remembered by the help of the diagram known as the *square of opposition*.



This shows at a glance the name of the opposition between any one proposition and all the rest. The most important kind of opposition is the *contradictory*. What is its exact nature? What is, for example, the nature of the relation existing between the propositions—

All metals are heavy and *Some metals are not heavy.*

Clearly, if the first be true, the second cannot possibly be true, or we should have a violation of the Law of Contradiction, for in that case certain metals would be heavy and would not be heavy. Similarly, if the second be true, the first cannot be true. Hence, of two contradictories, both cannot be *true*. Can they both be *false?* Clearly not. If *all metals are heavy* is not true, then there are at least some metals of which heaviness cannot be predicated, this being the only conceivable circumstance that can make the statement, *all metals are heavy*, a false one. Therefore, if the first is false, the second is true. And similarly, if the second is false, the first is true. Hence, of two contradictories, both cannot be false. But to say of contradictories that both cannot be true and both cannot be false, is the same as saying that *one must be true and one false.* This is the characteristic of contradictory opposition, which might in fact be defined as the relation existing between two propositions, one of which must be true and one false. To *contradict* a statement is to say that such statement is *not altogether* true; if we go beyond this, and declare that the statement is *altogether false*, we are asserting the *contrary*. To disprove a universal proposition we need only establish the *contradictory*, which can be done by adducing one single instance which does not agree with the general assertion.

Thus, the proposition, *all birds fly*, may be *disproved* or *contradicted* by adducing the single case of the ostrich,

which does not fly ; for such disproof, there is no need to rush to the *contrary assertion* that *no birds fly*.

The student will easily see that of two contraries both may be *false*, but both cannot be *true*. Thus, *all birds fly*, and *no birds fly*, clearly cannot both be true, but both are, in fact, false.

If we consider the relation between I and O we see that they are in a sense contrary, for I and O differ in quality only as do A and E, but they clearly are not so contrary as are A and E, for these are *inconsistent*, whereas I and O are not. Thus

All swans are white, and *No swans are white*,

are utterly inconsistent, but *some swans are white* and *some swans are not white*, may be, and in fact are, both true. Of two sub-contrary propositions, then, both may be *true*. Can both be *false ?* Since the *contradictory* of I is E, it follows from what has been said above, that if I is false, E is true, and, clearly, if E is true, O must be true. If, then, I is false, O must be true, and similarly, if O is false, I must be true. Hence, I and O cannot both be false, but can both be true.

Of two propositions between which there is *subaltern* opposition, one, the *particular*, is called the *subaltern*, and the other, the universal, is called the *subalternant*. It is evident that the truth of the subaltern is contained in, and may be inferred from, that of the subalternant, but the truth of the subalternant cannot be inferred from that of the subaltern. Thus, if it is true that *all men are mortal*, it is evidently true that *some men are mortal ;* but, granted the truth of the latter, we should not be justified in inferring from it the truth of the former. From the proposition, *some metals float on water*, we cannot validly conclude that *all metals float on water*.

Granted the truth of SaP what immediate inferences by opposition can be made concerning the truth or falsity of SeP, SiP, and SoP?

1. The contradictory of SaP is SoP, and since two contradictories cannot both be true, from the truth of SaP we can infer the falsity of SoP.
2. The falsity of SeP, which is the contrary of SaP, may also be inferred, for two contraries cannot both be *true*.
3. The truth of SiP may be inferred, for SiP is the subaltern of SaP, and its truth is, therefore, contained in the truth of SaP.

Granted that SaP is false, we can infer—

1. The truth of its contradictory, SoP;
2. Nothing of the truth or falsity of its subaltern, SiP;
3. Nothing of the truth or falsity of its contrary, SeP.

Granted the truth of O there can be inferred—

1. The falsity of its contradictory, SaP.
2. Nothing of its sub-contrary, SiP.
3. Nothing of its subalternant, SeP.

Similarly, if SoP is false it follows—

1. That its contradictory, SaP, is true.
2. That its sub-contrary, SiP, is true.
3. That its subalternant, SeP, is false.

In the same way the student can easily obtain the inferences capable of being made by opposition from the *truth* and from the *falsity* of E and I.

The results may be collected in tabular form—

IF	A	E	I	O
SaP is true ...	t.	f.	t.	f.
SaP is false ...	f.	?	?	t.
SeP is true ...	f.	t.	f.	t.
SeP is false ...	?	f.	t.	?
SiP is true ...	?	f.	t.	?
SiP is false ...	f.	t.	f.	t.
SoP is true ...	f.	?	?	t.
SoP is false ...	t.	f.	t.	f.

In this table t, f, ?, stand for *true*, *false*, *doubtful*, respectively.

Résumé of Chapter X.

I. Immediate inference may be—
   1. By opposition or
   2. By eduction (explained in Chapter XI.).

II. *Opposition* is the relation existing between two propositions having the same subject and predicate, but differing in quality, or quantity, or both.

There are four kinds of opposition—
   1. *Contradictory*, viz., that between A and O, or E and I.
   2. *Contrary*, viz., that between A and E.
   3. *Sub-contrary*, viz., that between I and O.
   4. *Subaltern*, viz., that between A and I or E and O.

III. Immediate inference by opposition is an inference from the truth or falsity of a given proposition as to the truth or falsity of an opposed proposition. All such immediate inferences follow from the following--

1. Of two *contradictories*, one must be true and one false.
2. Of two *contraries*, both cannot be true, but both may be false.
3. Of two *sub-contraries*, both cannot be false, but both may be true.
4. The truth of the *subalternant* involves the truth of the subaltern.

IV. Contradiction is the most important logical opposition.

Exercises on Chapter X.

1. What is meant by saying that the contradictory of a proposition is an assertion that such proposition is not altogether true, and that the contrary of a proposition is an assertion that it is altogether false?
2. *a*. If I is true, what can be inferred of the truth or falsity of A, E, O?
   b. If I is false, what can be inferred of the truth or falsity of A, E, O?
   c. If O is true, what is inferrible of the truth or falsity of A, E, I?
   d. If O is false, what is inferrible of the truth or falsity of A, E, I?

3. Give the contradictories of—
   a. None but the brave deserve the fair.
   b. All quadrupeds are animals.
   c. Some stars are not suns.
   d. None of the guests have arrived.
   e. Some animals are tame.
   f. A stitch in time saves nine.
4. Give the contrary or sub-contrary of all the propositions in Question 3, and say which you give.
5. Give the subaltern or subalternant of all the propositions in Question 3, and say which you give.
6. What can be inferred by opposition from the following?
   a. All birds do not fly.
   b. Some birds do fly.
   c. All birds fly.
   d. No birds fly.

CHAPTER XI.

Immediate Inference—Eduction.

Eduction is immediate inference, from a given premiss, to the truth of another proposition in which the subject and predicate are not the same respectively as the subject and predicate of the premiss. If we have as a given premiss—

All men are mortal,

by *eduction* we may infer that—

No men are immortal ;

We can also make the inference—

Some men are mortal ;

but as the subject, *men*, and the predicate, *mortal*, are unchanged, the inference is, in this case, obtained by opposition—not by eduction.

There are various kinds of eduction, three of the most important of which, viz., *conversion*, *obversion*, and *contraposition*, we proceed to explain.

Conversion is the interchange of the subject and predicate of a proposition, such conversion being logical only when the resulting new proposition is a *valid* inference from the original proposition. The proposition which is converted is the *convertend*, the new proposition obtained by conversion is the *converse*. It is evident that in conversion both subject and predicate have to be regarded from the point of view of *denotation* ; hence, it is clearer to write P's rather

than P in the symbolic form of propositions. Thus A will, in treating of conversion, be written *all S's are P's*, rather than *all S's are P*.

Now consider the conversion of—

All S's are P's.

The converse is—

All P's are S's.

Is this the *logical* converse? Clearly not, for no valid immediate inference can give knowledge which is not implied in the premiss, and *all P's are S's* does give such knowledge, for it predicates a fact definitely of the whole of P, and the convertend, *all S's are P's*, does not do this, for the predicate is, as we have already seen, undistributed. This objection to the validity of—

All P's are S's,

as an inference from—

All S's are P's,

does not apply if we write the converse in such a form as to make the quantity of P indefinite, as it is in the convertend. We have, then, as a valid converse, the proposition—

Some P's are S's.

Two points may be noticed about this converse. In the first place, it is of the same quality (affirmative) as the convertend; secondly, the term *P's*, which is undistributed in the convertend, is undistributed in the converse.

These are the two essential points to be noticed in any case of conversion. In fact, they may be given as the two rules for conversion—

Rule I. The quality of the proposition must not be changed.

Rule II. No term may be distributed in the converse unless it is distributed in the convertend.

We may use these rules for testing the converses of E, I and O. Is *No P's are S's* the logical converse of *No S's are P's?*

Rule I. is observed, for the quality is not changed, converse and convertend being both negative. Nor is Rule II. violated, for both terms are distributed in the convertend as well as in the converse.

By applying the rules the student can easily prove that the logical converse of—

Some S's are P's, is, Some P's are S's.

The conversion of SoP presents a difficulty. If we simply interchange subject and predicate of Some S's are not P's we have as the converse Some P's are not S's. This clearly does not violate Rule I., but it does violate Rule II., for the term *S's* is distributed in the converse, being the predicate of a negative proposition, and it is undistributed in the convertend. It is, therefore, invalid. Nor can this violation be avoided, except by so altering the process that it ceases to be conversion at all. Hence, SoP has no logical converse.

These results should be remembered—

All S's are P's, or SaP, converts to *Some P's are S's, or SiP.*
No S's are P's, or SeP, converts to *No P's are S's, or SeP.*
Some S's are P's, or SiP, converts to *Some P's are S's, or SiP.*
Some S's are not P's, or SoP, is inconvertible.

In the case of E and I the converse is E and I, that is, is of the same form as the convertend, propositions being of the same form when they are of the same quality and quantity. Hence, if the converse be re-converted we obtain the convertend. Thus—

No S's are P's has as its converse
No P's are S's, and the converse of this is
No S's are P's, or the original convertend.

When this is the case the conversion is said to be *simple*.

In converting SaP we obtain as converse SiP. In this case, then, the converse is not of the same form as the convertend. If we again convert the converse we do not obtain the original convertend. The conversion in this case is said to be *per accidens*, or by *limitation*.

It should be carefully noticed that the logical converse of *all S's are P's* is always *some P's are S's*, and that this is the case even if we know that the *simple* converse *all P's are S's* is, as a matter of fact, true. Such converse is never *valid*. Thus, the logical converse of—

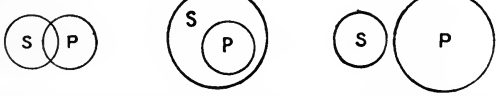
All equilateral triangles are equiangular, is
Some equiangular triangles are equilateral.

If we were to convert simply, we obtain as the converse—

All equiangular triangles are equilateral,

which is, as a matter of fact, true, but is logically invalid, as it cannot be inferred merely from the convertend.

The student should illustrate each case of conversion by means of Euler's diagrams. We will here illustrate the inconvertibility of SoP. SoP is represented by the three diagrams—



Now it is evident, to be valid, a converse must not be inconsistent with any possible case included in the convertend. If we convert SoP simply, we have *some P's are not S's*, which clearly is inconsistent with the second of the three diagrams representing SoP, and must, therefore, be an invalid inference. So any other form in which such converse can be written *as a converse* may be shown to be invalid.

Conversion is by far the most important form of eduction, and the student should make himself thoroughly understand it.

We proceed to *obversion*.

"Obversion is a process of immediate inference, in which from a given proposition we infer another, having for its predicate the contradictory of the predicate of the original proposition." (Keynes' *Logic*).

Consider the proposition—

All S's are P's.

To *obvert*, we must, according to the above definition, obtain a new proposition which shall have *non-P's* for its predicate, and which shall be inferrible from *all S's are P's*.

Clearly *no S's are non-P's* is such a proposition, which may be called the *obverse* of the original proposition, which is the *obvertend*. Three points should be noticed in this example.

1. The predicate is negatived.
2. The quality is changed, the obverse being negative, and the obvertend affirmative, and
3. The quantity is unchanged, both obverse and obvertend being universal. Hence, to obvert, we have merely to *negative the predicate, change the quality, and leave the quantity unchanged.* By applying this rule, we readily obtain the results shown in this table :—

Original Proposition or Obvertend.	Obverse.
A. All S's are P's.	E. No S's are non-P's.
E. No S's are P's.	A. All S's are non-P's.
I. Some S's are P's.	O. Some S's are not non-P's.
O. Some S's are not P's.	I. Some S's are non-P's.

The following are concrete examples of obversion:

A. All birds are bipeds.	Obvertend.
E. No birds are non-bipeds.	Obverse.
E. No Europeans are Hottentots.	Obvertend.
A. All Europeans are non-Hottentots.	Obverse.
I. Some apples are sweet.	Obvertend.
O. Some apples are not non-sweet.	Obverse.
O. Some men are not honest.	Obvertend.
I. Some men are non-honest.	Obverse.

Care is needed in negativing the predicate. If to the predicate of the obvertend there is an exact negative this can be used; thus, since *immortal* is the negative of *mortal*, we give—

No men are immortal,

as the obverse of—

All men are mortal.

More frequently than not, however, there is no exact negative term of the predicate of the obvertend, and whenever this is the case the negative should be formed by prefixing non- to the predicate term of the obvertend. Thus we must write the obverse of—

All apples are sweet, in the form

No apples are non-sweet.

The student might at first think that the obverse is—

No apples are sour,

reference to the definition of obversion as given above will, however, make it clear that it is not, for *sour* is not the *negative* but the *opposite* of sweet.

The last form of eduction that we have to consider is, *Contraposition*. Dr. Keynes defines contraposition as "A process of immediate inference in which, from a given

proposition, we infer another proposition, having the contradictory of the original predicate for its subject, and the original subject for its predicate."

If we *obvert* the proposition—

All S's are P's, we obtain

No S's are non-P's, as its obverse.

Now by *converting* this obverse we have—

No non-P's are S's,

and this is a proposition obtained by inference from—

All S's are P's,

and which has for its subject the contradictory of the predicate of the original proposition, and for its predicate the subject of the original proposition. Hence, according to the above definition, the whole inference must be a case of contraposition. The resulting proposition may be called the *contrapositive* of the original proposition, which *contrapositive* may, indeed, be defined as the *converse* of the *obverse*. The rule for contrapositing, then, is plain, *viz.*, *obvert and convert the obverse.*

The contrapositive of All S's are P's is, as we have just seen—

No non-P's are S's.

What is the contrapositive of E, *No S's are P's*?

The *obverse* is All S's are non-P's, and the *converse* of this is—

Some non-P's are S's,

which is therefore the *contrapositive* of—

No S's are P's.

If we attempt to contraposit I, *Some S's are P's*, we are met with a difficulty, for on obverting we obtain—

Some S's are not non-P's,

and this, being SoP, is incapable of conversion. Hence, no contrapositive can be obtained from an I proposition.

If we obvert O, Some S's are not P's, we obtain—

Some S's are non-P's,

the converse of which is

Some non-P's are S's,

which is therefore the contrapositive of

Some S's are not P's.

Our results may be tabulated thus—

Original Proposition.	Obverse.	Contrapositive.
SaP All S's are P's.	SeP No S's are non-P's.	SeP No non-P's are S's.
SeP No S's are P's.	SaP All S's are non-P's.	SiP Some non-P's are S's.
SiP Some S's are P's.	SoP Some S's are not non-P's	None.
SoP Some S's are not P's.	SiP Some S's are non-P's.	SiP Some non-P's are S's.

The following are concrete examples of contrapositives—

A. All Hottentots are Africans, Original proposition.
E. No non-Africans are Hottentots. Contrapositive.

E. No birds are quadrupeds. Original proposition.
A. All quadrupeds are non-birds. Contrapositive.

O. Some men are not honest. Original proposition.
I. Some non-honest beings are men. Contrapositive.

The student should illustrate contraposition by Euler's diagrams.

Résumé of Chapter XI.

I. *Eduction.*

1. Definition—Immediate inference from a given proposition to the truth of a new proposition, which differs in subject or predicate, or both, from the original proposition.
2. Example—*No men are immortal,* is an eduction from *all men are mortal.*
3. Kinds discussed—
   a. Conversion.
   b. Obversion.
   c. Contraposition.

II. *Conversion.*

1. Definitions—
   a. Conversion—the valid interchange of the subject and predicate of a proposition.
   b. The *convertend* is the proposition to be converted.
   c. The *converse* is the new proposition obtained by conversion.
   d. Conversion is *simple* when the converse is of the same form as the convertend.
   e. Conversion is *per accidens* when the converse is not of the same form as the convertend.
2. Rules for Conversion—
   a. Leave the quality unchanged.
   b. See that no term is distributed in the converse, unless it is distributed in the convertend.

3. Examples of Conversion—

a. A, *All S's are P's*, converts *per accidens* to I, *some P's are S's.*

b. E, *No S's are P's*, converts *simply* to E, *no P's are S's.*

c. I, *Some S's are P's*, converts *simply* to I, *some P's are S's.*

d. O, *Some S's are not P's*, is incapable of conversion.

III. *Obversion.*

1. Definitions—

a. Obversion is the inference, from a given proposition, of a new proposition, the predicate of which is the contradictory of the predicate of the original proposition.

b. The proposition to be obverted is the *obvertend.*

c. The proposition obtained by obverting is the *obverse.*

2. Rule for Obversion—Negative the predicate, change the quality and leave the quantity unaltered.

3. Types of Obversions—

a. A, *All S's are P's*, obverts to E, *no S's are non-P's.*

b. E, *No S's are P's*, obverts to A, *all S's are non-P's.*

c. I, *Some S's are P's*, obverts to O, *some S's are not non-P's.*

d. O, *Some S's are not P's*, obverts to I, *some S's are non-P's*

IV. *Contraposition.*

1. Definitions—
   a. Contraposition is the conversion of the obverse.
   b. The proposition obtained by contraposition is called the *contrapositive.*
2. Rule for contraposition :—*Obvert, and convert the obverse.*
3. Types of contraposition—
   a. A, *All S's are P's,* contraposits to E, *no non-P's are S's.*
   b. E, *No S's are P's,* contraposits to A, *all S's are non-P's.*
   c. I, *Some S's are P's,* is incapable of contraposition.
   d. O, *Some S's are not P's,* contraposits to I, *some non-P's are S's.*

Exercises on Chapter XI.

1. Distinguish between eduction and immediate inference by opposition.
2. Convert—
   a. Some stars are self-luminous.
   b. Some metals are not so heavy as water.
   c. All Europeans are white.
   d. All minerals are dug out of the earth.
   e. P struck Q.
   f. All that glitters is not gold.
3. Contraposit the above where possible.
4. Obvert the propositions in Question 2.
5. Illustrate the conversion of SaP, SeP, and SiP by Euler's diagrams.

6. Illustrate the contraposition of SaP by means of Euler's diagrams.
7. All equilateral triangles are equiangular. What can be inferred from this by conversion, by obversion, and by contraposition ?
8. What kinds of inferences are the following ? Say whether they are valid or not.
   a. Our knowledge must be gained from books, for books are a source of instruction.
   b. All triangles are trilateral, therefore, all trilateral figures are triangles.
   c. All that glitters is not gold, therefore, gold does not glitter.
   d. All wise students study hard, therefore, none who do not study hard are wise students.
   e. A met B, therefore, B met A.
9. Explain clearly why SiP cannot be contraposited.
10. Convert, obvert, and contraposit—
    Things which are equal to the same thing are equal to one another.

CHAPTER XII.

The Predicables.

In the last two chapters we have considered the most important relations existing between different propositions having the same or closely connected subjects and predicates; we have now to consider the different possible relations between the predicate and subject of the same proposition. The different classes into which predicates may be arranged by considering the relation in which they stand to their subjects, are known as the *predicables*. In every proposition something is affirmed or denied of the subject; what is so affirmed or denied is a *predicate*, what can be so affirmed or denied is a *predicable*. Aristotle (B.C. 384—322) arranged the predicables into *four* classes. His scheme has, however, completely given place to that of Porphyry (A.D. 234 to 304), who arranged the predicables under five heads.

In Porphyry's arrangement—

The Predicables are	1. Genus	Genus*
	2. Species	Species
	3. Difference, or	Differentia
	4. Property	Proprium
	5. Accident	Accidens.

* Singular, genus, species, differentia, proprium, accidens. Plural, genera, species, differentiæ, propria, accidentia.

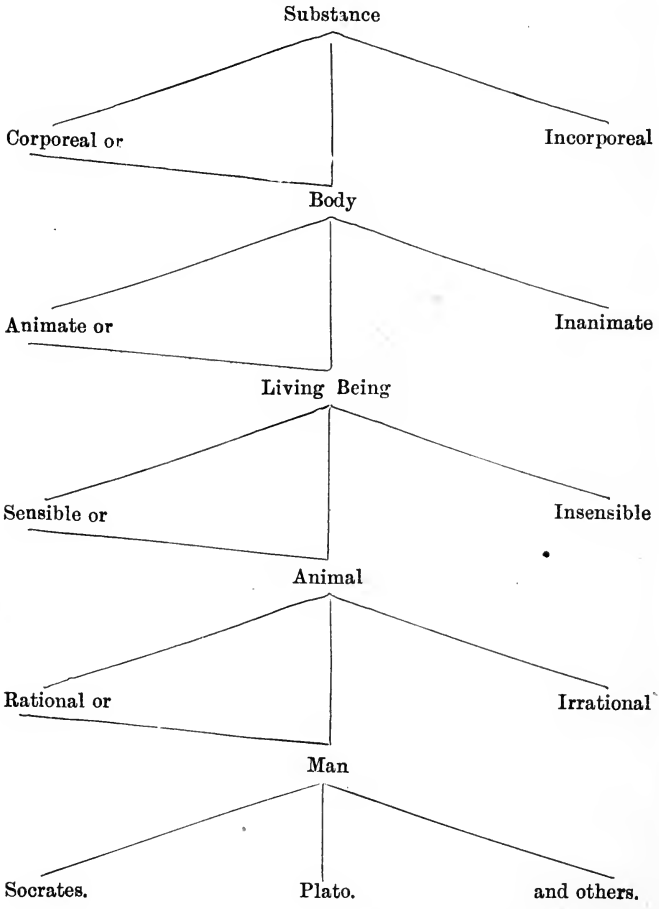
The second column gives the Latin names of the predicables. These are often used and should therefore be carefully remembered.

Any class regarded as consisting of two or more smaller classes is a *genus;* and the smaller classes which together constitute the *genus* are *species.* Thus, *triangle* is a *genus*, the *species* of which are scalene triangle, isosceles triangle, and equilateral triangle. In the proposition, *apples are fruit*, the predicate *fruit* is a *genus*, in relation to the subject *apples*, which is a *species*, in relation to the predicate *fruit.*

The term predicable itself is the name of a *genus*, the *species* of which are, *genus*, *species*, *difference*, *property* and *accident.* It is clear that *genus* and *species* are relative, for the definition of either involves that of the other; each is intelligible only in its relation to the other. It must be carefully noticed that the same term may at one time be the name of a genus and at another the name of a species, for whether a class is a genus or species depends entirely upon how we regard such class; regarded as a class consisting of sub-classes it is a genus, but regarded as a sub-class of a larger class it is a species. Thus, in *apples are fruit*, apples are a *species* of the *genus* fruit; but in *golden russets are apples*, the class *apples* is a genus, one species of which is *golden russets.*

A class which cannot be divided into sub-classes, but only into individuals, is called a *lowest species* or *species infima*; a *genus* which cannot be regarded as a species of any larger class is a *highest genus* or *summum genus.* Every genus must, of course, contain at least two species. All the species which together constitute the genus, are said to be *cognate.*

Any genus, with reference to the species into which it is immediately divided, is called a *proximate genus*. The following table was given by Porphyry to illustrate the connection between *genus* and *species*, and is consequently known as the Tree of Porphyry.



Here *substance* being regarded as a class including all other classes, and included in no other class, is the *summum genus; Man* being divided not into sub-classes, but into individuals, is the *species infima. Corporeal substance, or body*, and *incorporeal substance*, are *cognate* species of the *proximate* genus substance. So the *proximate genus* of rational animal and irrational animal is *animal.* Since the genus is a class consisting of smaller classes or species, the denotation of the name of the genus, or generic term, is greater than that of the name of the species, or specific term, and hence its connotation is less. Thus, *rational animal* is the name of a species of the genus *animal;* and, clearly, *animal* has greater denotation than *rational animal*, and has less connotation, for *rational animal* connotes all that *animal* does, and, in addition, it connotes the attribute of *rationality.* In fact, it is this additional connotation of the specific term that determines whether or not anything belonging to the genus belongs also to the species. It serves to differentiate the species from all other cognate species. This excess of connotation of the specific term over that of the generic term is the *differentia*, the third of the predicables. It is clear, then, that the connotation of the specific term equals the connotation of the generic term, together with the *difference.* If we remember that the terms are used with reference to connotation, this may be expressed thus :—

Species-name = genus-name + differentia.

Thus :—

Rational animal or species-name	=	animal or genus-name	+	rational or difference.

The word *differentia*, it will be noticed, is also a purely relative term, having no meaning apart from *genus* and *species*.

It may be useful to notice that the *genus* answers the question: What? The species: What kind? For example; what is a triangle? A figure (the genus). What kind of figure? One bounded by three lines (the species). A *proprium*, or *property*, is an attribute common to every member of a class which forms no part of the connotation of the class-name, but follows as a necessary consequence from it. For example, it follows as a necessary consequence from the connotation of *equilateral triangle*, as given in its definition, that an equilateral triangle is equiangular. *Equiangularity* is, then, a property of equilateral triangles. Similarly, the attribute of having the sum of its angles equal to two right angles is a *property* of triangles, for it forms no part of the connotation of *triangle*, but can be logically deduced from it.

Clearly, then, a property is an essential property in the sense that it is, and must be, possessed by every member of the class included under the class-name.

An *accidens* is a quality which forms no part of the connotation of the class-name, and cannot be deduced from it. It is not an essential quality, for its presence or absence in an object in no way affects the position of such object in the class. Thus, that the table at which I am writing is square is *an accident*, as is also the fact that it is made of mahogany. Both these qualities might be absent without the table ceasing to be a table.

Accidentia may be *separable* or *inseparable*.

A *separable* accident is one that does not belong to every individual of a class. Thus, whiteness is an *accident* of some swans, but a *separable* accident, for some swans are not white.

An *inseparable* accident is one that belongs to the whole class. Thus, it is an inseparable accident of pianos that some of their keys are black.

Résumé of Chapter XII.

Predicables.

I. Definitions.

1. A *predicate* is something affirmed or denied of a subject.
2. A *predicable* is whatever can be affirmed or denied of a subject.

II. Names of Predicables.

1. *Genus* is any class regarded as divided into two or more sub-classes.
2. *Species* is one of the sub-classes into which the genus is regarded as divided.
3. The *difference* (Latin *differentia*) is the excess of connotation of the name of the species over that of the name of the genus.
4. A *property* (Latin *proprium*) is an essential quality which forms no part of the connotation of the class-name, but is deducible from it.
5. An *accident* (Latin *accidens*) is any quality having no connection with the connotation of the class-name.

Exercises on Chapter XII.

1. Give six examples of species, mentioning in each case the proximate genus.
2. The species is part of the genus, and the genus is part of the species. Explain how this can be.
3. Refer the following predicates to their proper predicable—
   a. The horse is a quadruped.
   b. Socrates is a man.
   c. An equilateral triangle is bound by three equal sides.
   d. The angle in a semi-circle is a right angle.
   e. Some men are six feet high.
4. Give the proximate genera of those of the following which may be regarded as species—
   Man, teacher, Julius Cæsar, city, violin, table.
5. Specific name = Generic name + differentia. Explain this.
6. Is *laughter* a property or accident of man?

CHAPTER XIII.

Definition.

One of the most prolific sources of error in reasoning is the use of terms without there being in the mind of the speaker any definite idea of the connotation of such terms. We think we have an accurate knowledge of the language we use, but a very slight examination will convince most of us that such is not the case. When the student uses or hears used such familiar terms as *freedom*, *slavery*, *education*, *constitutional*, *honourable*, *definition*, let him but ask himself what their exact meaning is, and he will quickly discover that in many cases his ideas of their meaning are too vague to be put into words. Even in cases where the meaning is apparently perfectly known, it is frequently a matter of great difficulty to accurately express such meaning in words. Every general term has a certain connotation, and we should never rest satisfied with our knowledge of this connotation until we can accurately express it in words, that is, until we can *define the term*.

A *definition* is a proposition which gives the connotation of a term. Note carefully that definitions are of *terms*, not of *things*. By *connotation of a term*, it will be remembered, is meant those attributes, and those only, which must be possessed by an object before such term can rightly be applied to it. Thus, in *man is a rational animal*, we have a proposition setting forth the connotation of man, viz.,

the attribute implied by the term *animal*, together with *rationality*. If a term changes in meaning, as is frequently the case, then, of course, its definition also changes. Further, since a definition is an expression of the connotation of a term, it is evident *non-connotative* terms cannot be defined, for they have no connotation. We have already seen that proper names and singular abstract terms are non-connotative, and they, therefore, do not admit of definition.

The connotation of many terms is exceedingly complex, and a definition setting forth such connotation in simple attributes would be excessively unwieldy. Hence, a definition generally gives the greater part of the connotation by using a term expressive of a group of attributes, the meaning of such term being, of course, supposed to be known. Thus, if we define a *barrister* as a *lawyer who pleads at the bar*, all the connotation of *barrister*, with the exception of *pleading at the bar*, is given in the term *lawyer*. *Barrister* may be regarded as a species of the genus *lawyer*, and as we have already seen—

Connotation of species-name = connotation of genus-name + difference.

The above may be written thus—

Connotation of *barrister* = connotation of lawyer + pleading at the bar.

Hence, the term barrister is defined by giving the *proximate genus* (lawyer), and adding the *difference* (*pleading at the bar*). In defining, it is always best to proceed in accordance with the old rule that definition should be *per genus et differentiam*, *i.e.*, by means of the *genus* and the *difference*. Hence, if we wish to define any term, the first thing to do is to determine the class (genus) to which it belongs, and then add the difference.

The following are the rules usually given, to be observed in framing a definition—

1. The definition must contain neither more nor less than the connotation of the term defined.
2. It should be more intelligible than the term defined, and must not, therefore, be expressed in language the meaning of which is, from any cause, obscure.
3. It must not contain the term defined, nor any term synonymous with it.
4. It should not be negative if it can be affirmative.

To these may be added the old rule given above, *viz.*,

5. All definitions should be *per genus et differentiam.*

Rule 1 is not of much service in framing a definition. It is rather a test to be applied to the definition after it has been made. If more connotation be given than the term possesses, the definition is said to be too *narrow*, for it will not apply to all things bearing the name defined. Thus, if the term monarch is defined as a "man having supreme power in a country," such definition gives too much connotation, for it sets forth *sex*, which is no part of the connotation of monarch; it is, therefore, too *narrow*, as it excludes *women* who are monarchs.

The rule may be violated by giving too little, as well as by giving too much, connotation, in which case the definition is too *wide*, for it includes more *things* than rightly form the denotation of the term defined. Thus, if we were to define *hat* as *clothing for the head*, our definition would be too wide, for *clothing for the head* includes caps, turbans, bonnets, etc., as well as *hats*.

This rule is a very difficult one to avoid violating. It is often almost impossible to say precisely what the connotation of a term is, and especially is this the case if

the term is the name of a common object. To define may seem to be easy enough, but let the student try to frame accurate definitions of such common terms as *table*, *stool*, *chair*, *desk*, *hat*, *carriage*, and he will at once discover how difficult it is to avoid breaking the very first rule of logical definition.

The student should notice carefully that a definition gives *connotation*; if *properties*, or *accidents*, or both, are given, we have a *description* and not a *definition*.

Rule 2.—The reason for this rule is obvious. If connotation be given in terms less intelligible than the term defined, one object of the definition is defeated, for the meaning of the term is not made clearer by such a definition. Thus one's knowledge of the meaning of *soul* is not much improved by Aristotle's definition of it as "the first *entelecheia* of a natural body which has potential life". *Fluency* might be defined as the *exuberance of verbosity*, but such definition would hardly make clearer one's idea of fluency.

When this rule is violated the definition is said to define the *obscure* by the *more obscure (obscurum per obscurius)*, or the *unknown* by the *more unknown (ignotum per ignotius)*. This rule is also violated by the employment of metaphors in defining; thus, it is no definition of bread to say that it is the *staff of life*.

Rule 3.—The violation of this rule gives rise to what is known as a circle in defining (*circulus in definiendo*). Thus, if we define a metal as *one of the metallic elements*, we make no advance in knowledge, but rather travel in a circle and return to the place whence we started; if we do not know what a *metal* is neither do we know what *metallic* is. To define *life* as the *sum of the vital functions* is to commit

the same fault, for the word *vital* is from the Latin, *vitalis*, which, again, is from *vita*, the Latin word for *life*. Definitions in English are especially liable to this fault, as it frequently happens that a pure English word has a corresponding synonym derived from Latin.

Rule 4.—The definition of a purely negative term is naturally, negative. Thus, *alien* is a negative term, and its definition, which may be given as *one who does not belong to the British Empire*, is also negative.

Résumé of Chapter XIII.

I. Definitions are necessary—
   1. To make clear the meaning of terms.
   2. To fix such meanings.

II. Definitions.
   1. *Definition:*—A proposition setting forth the connotation of a term.
   2. Rules for defining.
      a. The definition must contain neither more nor less than the connotation of the term defined.
      b. It must be more intelligible than the term defined.
      c. It must not contain the term defined.
      d. It should be affirmative whenever possible.
      e. It should be *per genus et differentiam.*
   3. *Non-connotative* terms are incapable of being defined.

Exercises on Chapter XIII.

1. What is a definition ?
2. What is the difference between a *definition* and a *description* ?
3. What is meant by definition *per genus et differentiam* ? Give examples.
4. Which of the following terms cannot be defined and why ? School, college, honesty, Cæsar, horse, England.
5. Define the terms capable of definition in Question 4.
6. Criticise the following definitions taken from an English Dictionary—
   a. An auditor is one who audits accounts.
   b. An atlas is a collection of maps.
   c. A net is a reticulated fabric decussated at regular intervals.
   d. A burgess is an inhabitant of a borough.
   e. An apple is the fruit of the apple tree.
   f. An alley is a place along which one may go.

CHAPTER XIV.

Logical Division.

Logical Division is closely connected with definition, bearing as it does, much the same relation to the *denotation* of a term that definition does to the *connotation*. As to *define* is to unfold connotation, so to *divide* is to unfold, or analyse in an orderly way, denotation. It is called *division*, for an orderly analysis of the denotation of a term can be made only by regarding the term as the name of a genus, and by dividing such genus into its constituent species. The genus to be divided is called the *totum divisum*, or *total divided*, and the species or sub-classes into which it is divided, the *membra dividentia*, or *dividing members*.

Thus, if the genus *animal* be divided into the two species *rational animal* and *irrational animal*, *animal* is the *totum divisum*, and *rational animal* and *irrational animal*, the *membra dividentia*.

Before any class can be divided into sub-classes, some attribute or attributes must be thought of, on the presence, or absence, or the varying degree, of which the division may be made to depend. Thus, if I wish to divide the genus *flowers*, I first think of some attribute, *e.g.*, colour, variation of which will enable me to divide *flowers* into species.

Here *flowers* is the *totum divisum*, *white flowers*, *etc.*, are the *membra dividentia*, and *colour* is the attribute on which the division is based, or the *fundamentum divisionis*, as it is technically named.

If *plants* be divided into flowering-plants and non-flowering plants the *fundamentum divisionis* is the attribute *flower-producing*, the presence or absence of which serves as a basis of the division.

In the chapter on the *predicables* we have already seen that the species of any genus may themselves become genera for further division, which is then called *sub-division*. It is clear that for each step in the sub-division we shall require a fresh *fundamentum divisionis*. Thus, after having divided the genus *books* into the species *English books*, *French books*, etc., we may regard *English books* as a genus to be further divided into *species*, but we can no longer divide on the basis of the language in which printed, for all are printed in English ; a fresh *fundamentum divisionis* is needed, *e.g.*, size. We can then divide the genus *English books* into *English quarto books*, *English octavo books*, and so on.

There are certain processes to which the name *division* is applied, which should be carefully distinguished from *logical division*. *Physical division*, or *physical partition*, is a division of a unit into the parts of which such unit is formed, as, for instance, an individual house may be divided into the bricks, mortar, wood, etc., of which it is built. Another form of division is what is properly called *metaphysical division*, which by *abstraction* divides an individual object into the

qualities of which it may be said to consist. Thus, an orange may be regarded as an object consisting of a collection of qualities, such as yellow colour, a certain shape, a certain taste, etc. Logical division differs from both these in being applied to *classes* only, and not to *individuals*.

Certain rules have been given for carrying out a logical division; they are the following:—

1. Each step in the division must be founded upon one *fundamentum divisionis*.
2. The species when added together must equal the *proximate genus*.
3. The division must be gradual.

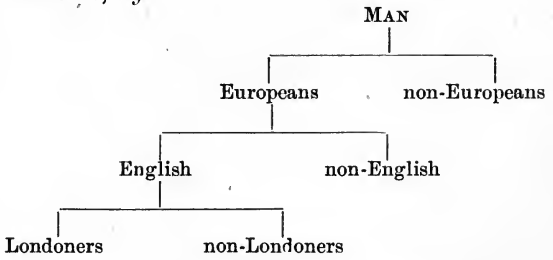
Rule 1.—The necessity for observing this is evident. If in dividing the genus *books* we choose size and subject matter as two *fundamenta divisionis*, we shall have two places in our division for each individual book. Where, for instance, shall we put an octavo book on Logic? Shall we put it in the *octavo class*, where it ought to go in virtue of its size, or in the class of Logic books, where it should go in virtue of its subject matter? We have what is called a *cross division*, which may be defined as the faulty form of division that results from its being based on more than one *fundamentum divisionis*.

The one *fundamentum divisionis* applies of course only to the *cognate* species. Every successive step in the division must have a fresh *fundamentum divisionis*. Thus, in dividing books according to subject matter, we should have as one of the cognate species *music books*. If now we regard this as a genus to be further divided, clearly we must have a fresh *fundamentum divisionis*, *e.g.*, size, in which case our division would result in *folio music books*, *quarto music books*, etc., as cognate species.

Rule 2.—If the sum of the cognate species be less than the genus, some part of the latter remains undivided, and the division is therefore not complete; and if it be greater we must have some things included in the species which do not belong to the genus at all. This rule does not help us much; it merely says that in dividing we should be careful to leave none of the *totum divisum* undivided.

Rule 3.—The old logicians gave this rule in the words *divisio non faciat saltum*, that is, *the division must not make a leap*. This rule will be kept if we always take care to make the species those of the proximate or next higher genus. Thus, it would be illogical to divide Europe at once into *parishes*; the proximate genus of *parish* might possibly be *union*, *barony*, or *county*, but is certainly not Europe.

The most perfect form of logical division is that in which at each step the genus is divided into two species, one species having a certain attribute and the other not possessing such attribute, *e.g.*—



Such a division is said to be by *Dichotomy*, from two Greek words meaning "a division into two."

In division by dichotomy cross division is impossible, for an object cannot both possess an attribute and not possess it, which it must do to belong to both the cognate species. Moreover, every object in the genus to be divided must, by

the Law of Excluded Middle, either possess any given attribute or not possess it, and hence every object will have its place in one or the other of the cognate species. Therefore, the second of the above rules will not be broken in a division by dichotomy if carefully carried out.

Division by dichotomy is, in many cases, however, too tedious. When we are certain of the number of the subclasses it is better to divide the genus into such classes at once. It would be absurd to divide England into Middlesex and non-Middlesex, as cognate species; and then non-Middlesex into Surrey and non-Surrey, and so on. Since the number of counties is known, the rules may be kept by dividing at one step into counties.

The Tree of Porphyry given in the lesson on the predicables is a good example of logical division by dichotomy.

Résumé of Chapter XIV.

Division.

I. *Definitions.*

1. Logical division is an orderly analysis of the denotation of a term.
2. *Totum divisum* is the whole class to be divided.
3. *Membra dividentia* are the sub-classes in the division.
4. *Fundamentum divisionis* is the attribute, the presence or absence or varying degree of which determines the class of any object.

II. Processes to be distinguished from logical division.

1. *Physical division* is the division of an individual object into its material elements.

2. *Metaphysical division* is the division by abstraction of an individual object into the qualities which may be regarded as constituting it.

III. Rules for logical division.

1. Each step in the division must be founded on one *fundamentum divisionis.*
2. The species when added together must equal the proximate genus.
3. The division must be gradual.

IV. Division by dichotomy is that form of division in which each genus is divided into *two* species determined by the presence or absence of some attribute.

Exercises on Chapter XIV.

1. What is logical division?
2. Distinguish *logical* division from *physical* division, and from *metaphysical* division.
3. Explain *fundamentum divisionis.*
4. Divide book, teacher, school.
5. Criticise the following divisions—
   a. Books into folio, quarto, octavo, French and English.
   b. Quadrupeds into horses, ponies, mules, carnivora, and mammalia.
   c. Knowledge into useful, useless and harmful.
   d. Thieves into pickpockets, pilferers, highwaymen and pirates.
   e. Pictures into sacred, historical, imaginative, and realistic.
   f. Constitutions into good and bad.

CHAPTER XV.

The Syllogism.

We have already (Chapter IV.) seen what constitutes a syllogism. We have in the present chapter to consider under what circumstances we may rely on the conclusion of a syllogistic argument as being valid.

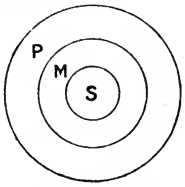
A syllogism has been defined as "a reasoning, consisting of three categorical propositions (of which one is the conclusion), and containing three, and only three, terms" (Keynes). Taking this as our definition of the syllogism, we see that every syllogism consists of three propositions, and contains three terms. These terms are the *middle term*, the *major term*, and the *minor term*. These have been already defined (Chapter IV.) and the student, if he has not already done so, must firmly fix in his mind that the *middle term* is the one which does not occur in the conclusion, that the *major term* is the predicate of the conclusion, and the *minor term* the subject of the conclusion. Consider the syllogism—

All M's are P,
All S's are M,
therefore All S's are P.

Here the proposition written last is the *conclusion*, for it is clearly the inference drawn from the other two, which are the *premisses*,

The three terms are S, M, P, each of which occurs twice. M is the middle term, for it is the term which does not occur in the conclusion; S is the minor term, being the subject of the conclusion; and P is the major term, being the predicate of the conclusion.

A syllogism like the above may be typically represented by the Eulerian diagrams, thus—



In this, for the sake of simplicity, only one diagram is used to represent SaP. According to this diagram S stands for a class *smaller* than the M class, P stands for a class *larger* than the M class, M denoting a class intermediate in size between the classes denoted by S and P. It is for this reason that they received the names, *minor*, *major* and *middle* respectively. These names are, however, used in the technical sense defined above, for the mutual relation implied by the names *minor*, *major* and *middle* does not always hold.

The premiss containing the *minor* term is called the *minor premiss*, and that containing the *major* term is called the *major premiss*. In the strict logical order of the syllogism the major premiss stands first, the minor second, and of course the conclusion last. This order is, however, in practice by no means always observed. Frequently the conclusion stands first as in the syllogism—

He is honest	(conclusion)
For he is an Englishman	(minor premiss)
and All Englishmen are honest	(major premiss)

The student should now be in a position to understand the rules of the syllogism. As usually given they are six in number, to which are added three additional ones deducible as corollaries from them.

The rules are—

1. Every syllogism contains three, and only three, terms.
2. Every syllogism consists of three, and only three, propositions.
3. The middle term must be distributed once at least, and must not be ambiguous.
4. No term may be distributed in the conclusion which was not distributed in one of the premisses.
5. From negative premisses nothing can be inferred.
6. If one premiss be negative, the conclusion must be negative, and conversely, to prove a negative conclusion one premiss must be negative.

The three supplementary rules deducible as corollaries from the above, are—

7. From two particular premisses, nothing can be inferred.
8. If one premiss be particular, the conclusion will be also particular.
9. From a particular major and a negative minor premiss, nothing can be inferred.

These rules are of such supreme importance, that they should be learned thoroughly at once. If any complete thought, when put into syllogistic form, is found not to violate any of these rules, the conclusion must necessarily be valid. Rules 1 and 2 are very important as a means of testing any given argument as to whether it is a syllogism or not; they are, however, of little or no practical use as tests of the validity of the syllogism.

The first part of Rule 3 is exceedingly important, and is constantly being violated by students who have not studied Logic. One of the commonest experiences of the teacher of Logic is, after having explained what a syllogism is, to have given him, as valid syllogisms, examples of syllogisms which violate Rule 3. Here are a few actually given by students—

All flowers are pretty,
All roses are pretty,
therefore All roses are flowers.

All children are playful,
Tommy is playful,
therefore Tommy is a child.

All quadrupeds are animals,
The horse is an animal,
therefore The horse is a quadruped.

In the first of these the middle term is *pretty*, and this is the predicate of both premisses, which are affirmative; it is therefore undistributed. When any rule of the syllogism is violated, a *fallacy* is said to be committed; in this case we have the *fallacy of the undistributed middle term*, or more briefly, the *undistributed middle*. Similarly, in both the second and third of the above syllogisms we have the fallacy of the undistributed middle. The student will now readily understand why the fourth syllogism given in Chapter II. is invalid. It is—

All coins are useful things,
All shillings are useful things,
therefore All shillings are coins.

The middle term *useful things* is not distributed in either premiss of the syllogism which, therefore, is guilty of the undistributed middle.

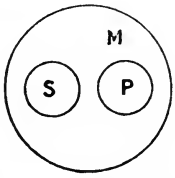
In all the above examples the conclusions are *true* and it is this which is so likely to mislead the student into thinking that they are valid. Express any of them in symbols and the fallacy is more apparent. Thus for "coins", "useful things", "shillings", the major, middle and minor terms respectively, put P, M, S, respectively.

The syllogism now is—

All P's are M,
All S's are M,
therefore All S's are P.

It is at once evident that it contains the undistributed middle.

This fallacy may be clearly illustrated by Euler's diagrams. The diagram—



clearly satisfies the premisses and is yet inconsistent with the conclusion of the syllogism, which is therefore invalid, for, in a valid syllogism, if the premisses are true the conclusion is also necessarily true.

The second part of Rule 3 is also important. It is easy for any one who has once understood what is meant by the *undistributed middle term* to avoid the violation of the first part of this third rule, but it is a much more difficult matter to avoid violating the second part of this rule. The violation of the second part of the third rule of the syllogism is known as the *fallacy of the ambiguous middle.*

A term is said to be ambiguous when in different parts of the same argument it has different meanings. Thus, in the syllogism—

Light dispels darkness ;
Feathers are light ;
therefore Feathers dispel darkness.

The term *light* has, evidently, two meanings, and is, therefore, *ambiguous.* Moreover, *light* is the middle term in the above syllogism, hence, the syllogism is invalid, containing the fallacy of the ambiguous *middle term.* In this case the ambiguity is easy enough to detect, and the student may think that the ambiguous middle can always easily be avoided. There is no fallacy that is more abstruse and more difficult to avoid falling into. Let the student try to discover the fallacy in the following syllogism, and he will at once see that the fallacy of ambiguous middle is not always easily detected—

A man deserves no credit for doing what he cannot possibly help doing ;
A benevolent man cannot possibly help relieving distress ;
therefore A benevolent man deserves no credit for relieving distress.

If we carefully examine the precise meanings of the terms we see that "cannot possibly help" is used in different senses in the two premisses. These words, moreover, form part of the middle term, hence, the above syllogism is guilty of the fallacy of *ambiguous middle term.*

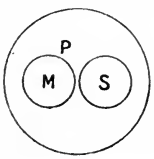
When a term is used in the same argument in two senses it is in reality *two terms* which happen to be spelled and pronounced alike, so that a syllogism containing an ambiguous middle term has really four terms and thus

violates the first rule. Every case of the fallacy of ambiguous middle may be regarded as a case of the *fallacy of four terms.*

The fourth rule of the syllogism is also an important one. The student will find no difficulty in detecting any cases of its violation. Consider the syllogism—

All M's are P,
No S's are M,
therefore No S's are P.

The major premiss in this is an A proposition and its predicate, which is the *major* term, is therefore undistributed; the conclusion, being an E proposition, distributes its predicate, which is the major term. Hence, the *major* term is distributed in the conclusion, but not in the major premiss, and the syllogism therefore violates the fourth rule. This is an example of the fallacy known as the *illicit process of the major term*, or more shortly, the *illicit major*. The above syllogism may be represented by the diagram—



which is in accordance with the premisses, but inconsistent with the conclusion. A concrete example of the *illicit major* is—

All apples are fruit,
No pears are apples,
therefore No pears are fruit.

The *invalidity* of the conclusion is, in this, at once noticed, because it is seen to be false. If however, we

have a syllogism guilty of the same fallacy, but having a conclusion known to be true, the fallacy is much more likely to be overlooked. Thus, the syllogism—

All Hottentots are Africans,
No English are Hottentots,
therefore No English are Africans,

is invalid, from its violating rule 4, although, knowing the *truth* of the conclusion, we are apt to conclude that it is valid.

Similarly we may have an *illicit process of the minor term*. Thus the syllogism—

All M's are P,
Some S's are M,
therefore All S's are P,

clearly has the minor term S undistributed in the minor premiss and distributed in the conclusion. The *illicit minor* is less frequent and more easily detected than the *illicit major*. A concrete example is—

All rogues deserve punishment
Some Englishmen are rogues,
therefore All Englishmen deserve punishment.

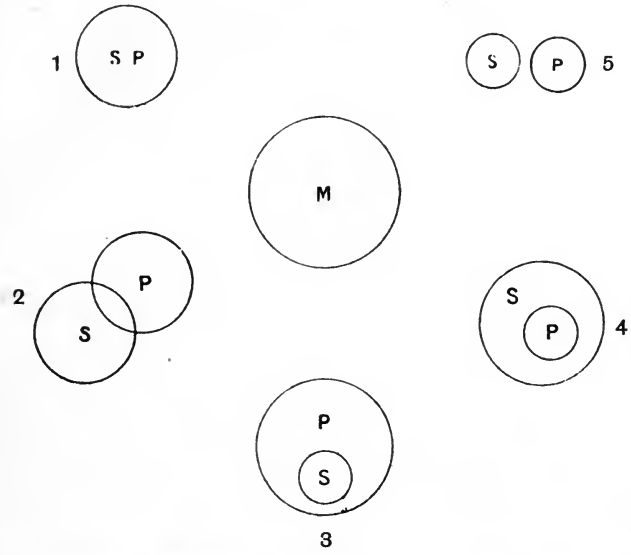
Rules 3 and 4 are the only ones that give any difficulty in applying. To be able to apply these two rules the student must have perfectly clear ideas on the subject of distribution of terms.

Rule 5 may be clearly illustrated by diagrams. To represent the premisses—

No P's are M,
and No S's are M,

we must be careful to make both the P circle and the S circle outside of the M circle, but the premisses give us no conditions as to the relation of S and P. In fact, the S and

P circles may have any one of the five relations possible between them. This may be shown thus—



the premisses allowing of all the five relations between S and P shown. Hence, we can no more make any inference from the premisses than from the mere mention of the terms S and P. If this is the case with *universal premisses*, still more so is it the case with *particular premisses*.

Rule 6. If one premiss is negative, the other must be positive, by Rule 5. Hence, in a syllogism having one premiss negative, of the *major* and *minor* terms, one is affirmed to agree wholly or partially with the middle term, and the other is affirmed to wholly or partially be separated from the middle term, and therefore the major and minor terms must be wholly or partially separate, that is, the conclusion in such a syllogism is negative.

Rule 7 may be deduced from the preceding six, thus :— If the two premisses are particular, they must be II, IO, OI, or OO. The premisses OO are excluded by Rule 5. II would clearly give undistributed middle, for I distributes neither its subject nor its predicate. Now IO or OI will give a negative conclusion, if any at all, by Rule 6. Therefore, the major term must be distributed to avoid *illicit major*; and the middle must be distributed to avoid undistributed middle. Hence, two terms must be distributed in the premisses. But OI or IO distribute only one term, *viz.*, the predicate of O; hence, any conclusion from them as premisses, must be obtained by means of an undistributed middle, or an illicit major. Therefore, two particular premisses give no conclusion.

Rule 8. The only possible pairs of premisses of which one is particular, are:—AI, AO, EI, EO, and of these, EO are excluded by the fifth rule. The premisses AI, distribute only one term between them, *viz.*, the subject of A. This must be the middle term, to avoid undistributed middle; hence, by Rule 4, no term can be distributed in the conclusion which must therefore be *particular*. The pairs of premisses, AO and EI, each distribute two terms. One must be the middle term, and the other the major term, as the conclusion is negative by Rule 6, and, therefore, distributes its predicate. Hence, the minor term cannot be distributed in the premiss, and, therefore, cannot be distributed in the conclusion, which is consequently a particular proposition.

Rule 9. This may be deduced from the first six rules, as follows :—The minor premiss being negative, the major must be affirmative by Rule 5, and it is particular by Rule 9 itself. Therefore, the major premiss can distribute no term,

and the *major* term consequently is undistributed in its premiss. The conclusion, however, being negative by Rule 6, distributes the major term, and we must have the *illicit major*. This is clearly seen in an example—

Some M's are P,
No S's are M,
therefore Some S's are not P,

which clearly is guilty of illicit major.

Résumé of Chapter XV.

I. Definitions.
1. A syllogism is a reasoning consisting of three propositions and containing three, and only three, terms.
2. The *middle* term is the term which does not occur in the conclusion.
3. The *major* term is the predicate of the conclusion.
4. The *minor* term is the subject of the conclusion.
5. The *minor* premiss is the one containing the minor term.
6. The *major* premiss is the one containing the major term.

II. Rules.
1. Six primary rules—
a. Every syllogism has three, and only three, terms.
b. Every syllogism consists of three, and only three, propositions.
c. The middle term must be distributed once at least and must not be ambiguous.

d. No term may be distributed in the conclusion which is not distributed in its premiss.

e. From negative premisses nothing can be inferred.

f. If one premiss be negative, the conclusion must be negative. Conversely, to prove a negative conclusion, one premiss must be negative.

2. Three corollaries from the above.

a. From two particular premisses nothing can be inferred.

b. If one premiss is particular the conclusion is so also.

c. From a particular major and negative minor nothing can be inferred.

Exercises on Chapter XV.

1. Point out the major, minor, and middle terms in the following syllogisms and test their validity with reference to the rules of the syllogism.

a. All vegetables are useful,
All cabbages are vegetables,
therefore, All cabbages are useful.

b. All vegetables are useful,
All cabbages are useful,
therefore, All cabbages are vegetables.

c. The highest good is the end of life,
Death is the end of life,
therefore, Death is the highest good.

d. All animals can move,
Protococcus can move,
therefore, Protococcus is an animal.

e. All metals are elements,
Brass is a metal,
therefore, Brass is an element.

2. Put the following arguments into strict logical form and test their validity.
   a. The atmosphere has weight, for it is a material substance, and all material substances have weight.
   b. All planets move round the sun, therefore the earth moves round the sun, for it is a planet.
   c. David was mad, for he scribbled on the walls, and madmen do so.
3. Express the arguments in Question 2 in symbols.
4. Illustrate the arguments in Question 1 by Euler's circles.
5. Test the following—
   a. All P's are M: All S's are M: therefore All S's are P.
   b. All P's are M: All M's are S: therefore All S's are P.
   c. No P's are M: No M's are S: therefore No S's are P.
   d. No M's are P: All S's are M: therefore No S's are P.
6. If the major term of a syllogism is the predicate of the major premiss, what is known about the minor premiss?
7. Prove that when the minor term is the predicate of the minor premiss the conclusion cannot be A.
8. Prove that two particular premisses give no conclusion.

CHAPTER XVI.

Figure and Mood of the Syllogism.

In the preceding chapter we have discussed the rules by which syllogistic arguments may be tested. In the present chapter we shall determine all the various forms which a valid syllogistic argument may take.

The form of a syllogism, as determined by the quality and quantity of the propositions forming it, is called the *Mood* of the syllogism. Thus, the syllogism—

All M's are P,
All S's are M,
therefore All S's are P

is of the mood AAA, which simply means that all the three propositions constituting it are universal affirmative propositions. Similarly, EAE, AAI, etc., are moods. The student must carefully note that in giving the mood of a syllogism the order of the propositions is the logical order, *viz.*, major premiss, minor premiss, conclusion. Thus, the mood EAE means that the major premiss is E, the minor premiss A, and the conclusion E. By the *figure* of a syllogism is meant the form it takes as depending on the order of the terms in the premisses. We have seen (Chapter XV.) that the order of the terms in the conclusion is invariable, for in every syllogism the predicate of the conclusion is the major term and the subject of the conclusion

the minor term. Hence, the empty symbolic form of the conclusion is S–P. In the premisses, however, the terms may occur in any order. Since each term occurs twice in any syllogism, and the conclusion contains the major and minor terms, it is clear that the terms which must occur in the two premisses of any syllogism are S, P, M, M. The middle term cannot occur twice in one premiss, for if it did the other premiss would be S–P or P–S, and with this the conclusion S–P would be identical or be obtained from it by immediate inference. This limits us to *four* possible arrangements of the terms in the premisses. They are—

1	2	3	4
M–P	P–M	M–P	P–M
S–M	S–M	M–S	M–S

These are known as the *first*, *second*, *third* and *fourth* figures respectively.

We may add the conclusion to each and we then have—

First Figure	Second Figure	Third Figure	Fourth Figure
M–P	P–M	M–P	P–M
S–M	M–S	M–S	M–S
S–P	S–P	S–P	S–P

The student should learn thoroughly the position of the terms in each of the four figures. This is most easily done by learning the position of M in each figure, for when the place of M is known the syllogism may be easily completed.

The possible number of valid moods may be determined by first considering how many different pairs of propositions can possibly stand as premisses and then considering what conclusions are justified by each valid pair of premisses. The major premiss may be A, E, I, O. If the major is A,

the minor may also be A, E, I, or O, without violating Rules 5 and 7, the rules which refer to the premisses. If the major is E, the minor cannot be E or O, by rule 5, and can therefore be only A or I. If the major is I, the minor can be only A, O and I both being excluded by Rule 7 and E by Rule 9. If the major is O, the minor can only be A, as E would be excluded by Rule 5, and I and O by Rule 7. This gives altogether eight valid pairs of premisses.

AA, AE, AI, AO.
EA, EI.
IA.
OA.

The pairs in which each premiss is universal will give a universal conclusion, and, therefore, also, the subaltern to such conclusion.

AI and IA can each only give a particular affirmative as conclusion by Rule 8 ; and AO, EI, OA can each only give a particular negative conclusion by Rules 6 and 8. Hence, altogether, there are 11 possible moods, viz.—

AAA, AAI, AEE, AEO, EAE, EAO,
AII, AOO, EIO, IAI, OAO.

Each of these moods will give four syllogisms, for they may be of any figure. We have to determine, then, how many of these are valid in each of the four figures. This can easily be done by writing them in each figure and testing by rules 3 and 4. Thus, AAA in the four figures is—

1.	2.
All M's are P,	All P's are M,
All S's are M,	All S's are M,
∴ All S's are P.	∴ All S's are P,

3.	4.
All M's are P,	All P's are M,
All M's are S,	All M's are S,
∴ All S's are P.	∴ All S's are P,

Here, 1 is valid ; 2 violates rule 3, giving undistributed middle ; and 3 and 4 both violate rule 4, giving the illicit minor.

If we test in this way, we shall obtain as valid—

In Fig. 1. AAA, AAI, EAE, EAO, AII, EIO,
In Fig. 2. EAE, EAO, AEE, AEO, EIO, AOO,
In Fig. 3. AAI, IAI, AII, EAO, OAO, EIO,
In Fig. 4. AAI, AEE, AEO, EAO, IAI, EIO.

Five of these are rejected as useless. They are—

AAI, EAO, in Fig. 1.
EAO, AEO, in Fig. 2.
and AEO, in Fig. 4.

In each of these, it will be noticed that the conclusion is *particular*, although the universal is justified by the premisses. The conclusion in such syllogism is said to be *weakened*. Thus, in Fig. 1, the premisses EA justify either E or O as conclusion, and we are not likely to be satisfied with O as conclusion, when E is justified by the premisses. Granted the premisses—

No fish have lungs,
All salmon are fish,

the conclusion, *some salmon have not lungs*, is valid, but such conclusion is hardly satisfactory since the premisses justify

No salmon have lungs, as conclusion.

Omitting the five moods with weakened conclusions, we are left with 19 valid and useful moods. There is, in reality, no necessity to retain these 19 moods in memory,

as any syllogism may always be tested by the rules. To enable students easily to remember the moods valid in each figure, the following mnemonic lines were devised more than six centuries ago—

Bārbărā, Cēlārēnt, Dărĭī, Fĕrĭō que prioris;
Cēsărĕ, Cāmēstrēs, Fēstīnŏ, Bărōcŏ, secundae;
Tertia, *Dārāptī, Dĭsămīs, Dātīsĭ, Fĕlāpton,*
Bōcārdō, Fērīsŏn, habet; Quarta insuper addit,
Brāmāntīp, Cămĕnes, Dĭmăris, Fēsāpŏ, Frĕsīson.

These lines contain in italics nineteen words, the vowels of which denote the nineteen valid moods of the syllogism. These words are merely coined for the purpose for which they are here employed, and have no meaning other than the technical meaning here given to them. They are used as the names of the moods they severally stand for. Thus the mood AAA is usually called *barbara*, the mood AOO, *baroco*, and so on.

The words in the mnemonic lines not italicised are real Latin words. They are—

Que, meaning *and*; in Latin placed after the word which it joins to previous words.

Prioris, meaning *of the first* (*figure*).

Secundae, meaning *of the second* (*figure*).

Tertia . . . habet, meaning *the third* (*figure*) *contains.*

Quarta insuper addit, meaning the *fourth* (*figure*) *in addition adds.*

Résumé of Chapter XVI.

FIGURE AND MOOD.

I. Mood.

1. Definition—Mood is the form of the syllogism as determined by the quantity and quality of the propositions of which it consists.
2. In a mood symbol such as AEE, the letters always denote the major premiss, the minor premiss, and the conclusion respectively.
3. There are 11 possible moods.

II. Figure.

1. Definition—the form of the syllogism as determined by the order of the terms in the premisses.
2. There are four possible figures.

a. First figure.	M–P
	S–M
b. Second Figure	P–M
	S–M
c. Third Figure	M–P
	M–S
d. Fourth Figure	P–M
	M–S

III. Combinations of moods and figures.

1. The valid and useful moods of Fig. 1 are—
   Barbara, *Celarent*, *Darii*, and *Ferio*.
2. In Fig. 2 are—
   Cesare, *Camestres*, *Festino* and *Baroco*.
3. In Fig. 3 are—
   Darapti, *Disamis*, *Datisi*, *Felapton*, *Bocardo* and *Ferison*.
4. In Fig. 4 are—
   Bramantip, *Camenes*, *Dimaris*, *Fesapo*, *Fresison*.

Exercises on Chapter XVI.

1. What is mood ?
2. What is figure ?
3. Test EIO in each of the four figures.
4. Test IAI in each of the four figures.
5. Why are there only negative conclusions in Fig. 2 ?
6. Why are there only particular conclusions in Fig. 3 ?
7. Give a concrete example of AEE in each figure. Which are valid ?
8. What rules are broken by *Bramantip* in the first three figures ?

CHAPTER XVII.

Reduction.

The oldest rule for testing the validity of syllogisms is Aristotle's *dictum de omni et nullo* (See Chapter V.). This rule is, however, directly applicable only to syllogisms in the first figure, which Aristotle regarded as the most perfect of the figures. Hence, before the *dictum* could be applied as a test, it was necessary to express in Fig. 1 all syllogisms not already in that figure. This was called the *reduction* of the figure. *Reduction* may be defined as the process of changing a syllogism from any mood and figure in which it may be, into another mood or figure. It is clear, from what has been said of conversion, that an argument stated in one figure may frequently be reduced to another figure, for the conversion of a premiss will often give an equivalent proposition, but such conversion necessarily changes the figure. Thus, take *Festino* of the second figure—

No P's are M,
Some S's are M,
therefore Some S's are not P.

By simple conversion of the major premiss, we have—

No M's are P,
Some S's are M,
therefore Some S's are not P,

and this is *Ferio* of the first figure.

If the student will again look at the mnemonic lines, containing the valid moods in the different figures as given in the last chapter, he will see that the only initials of the names of the different moods are B, C, D and F, and that these all occur in the first line, which gives the moods valid in Fig. 1. The initials of the moods in the other figures are the same as those of the first figure, to which they can be reduced. Thus, *Camestres* of the second figure, and *Camenes* of the fourth figure, on reduction to Fig. 1 become *Celarent.*

Further, the letters s, m and p have meaning. The letter *s*, when following a vowel, denotes that to reduce to Fig. 1, the proposition denoted by the preceding vowel must be *simply converted.* Thus, the *s* in *Festino* means, that to reduce *Festino* to *Ferio*, you simply convert the major premiss denoted by the preceding *e*. The letter *m* is the initial of the Latin *muta* which means *change*, and denotes that the premisses are to be interchanged. Thus, to reduce *Disamis* of Fig. 3, to *Darii* of Fig. 1, we have to simply convert the major premiss as indicated by *s*, to interchange the premisses, as indicated by *m*, and finally to simply convert the conclusion, as indicated by the last letter *s*. If we perform these operations on *Disamis*, that is, on—

Some M's are P,
All M's are S,
therefore Some S's are P,

it becomes—

All M's are S,
Some P's are M,
therefore Some P's are S,

or *Darii* of Fig. 1. In this it must be noticed that P is the minor and S the major term.

LIBRARY OF THE UNIVERSITY OF CALIFORNIA

The letter *p* following a vowel indicates that the proposition denoted by that vowel has to be converted *per accidens*. Thus— All M's are P,
All M's are S,
therefore Some S's are P,
or *Darapti* of Fig. 3 becomes, if we convert the minor premiss, *per accidens*, as indicated by the letter *p*—
All M's are P,
Some S's are M,
therefore Some S's are P,
or *Darii* of Fig. 1.

All moods in the second, third, and fourth figures, with the exception of *Baroco* and *Bocardo*, can be reduced to the first figure by conversion and interchange of the premisses. To reduce *Baroco* we must *contraposit* the major and *obvert* the minor premiss.

The *major*, all P's are M, when contraposited, gives —No non-M's are P.

The *minor*, some S's are not M, by obversion, gives —Some S's are non-M.

The conclusion, some S's are not P, remains the same— Some S's are not P.

The resulting syllogism is *Ferio* in Fig. 1, having *non-M* as its middle term.

Bocardo of Figure 3 is—
Some M's are not P,
All M's are S,
therefore Some S's are not P.

By contrapositing the major premiss and interchanging the premisses, we obtain—
All M's are S,
Some non-P's are M,
therefore Some non-P's are S.

This is *Darii* of Fig. 1, the minor term being *non-P*. If we now simply convert the conclusion and then obvert, we have—

Some S's are not P,

which is the original conclusion of *Bocardo*.

No provision is made in the mnemonic lines for the reduction of *Baroco* and *Bocardo* in this way. They were reduced by a special method called *reductio per impossibile*, or *reductio ad absurdum*. The initial *B* indicates that in the cases both of *Baroco* and *Bocardo*, the reduction is to *Barbara*. The premisses of *Baroco* being granted, viz.—

All P's are M,

Some S's are not M,

the conclusion, some S's are not P, either is or is not necessarily true. If the conclusion is false, its contradictory must be true, that is—

All S's are P

is true. This, along with the major premiss of *Baroco*, gives us a new syllogism in *Barbara*, viz.—

All P's are M,

All S's are P,

therefore, All S's are M.

This conclusion contradicts the minor premiss of *Baroco*, which is known to be true. Hence, if we disallow the truth of the conclusion of *Baroco*, and at the same time allow the truth of its premisses, we fall into self-contradiction. The proof of *Bocardo* by this method may be left to the student.

Reductio per impossibile is a round-about method of proof applied to these two cases, because they do not readily admit of reduction to the first figure. It is not usually applied to the other moods, because they can be so readily reduced to Fig. 1, to which Aristotle's *dictum* is directly applicable.

The student will understand now how full of meaning the mnemonic lines are. They have been described as "the magic words which are more full of meaning than any that were ever made."

The student will do well to notice the following peculiarities of the different figures.

Fig. 1. This is the only figure in which A, E, I and O can all be proved. The most important mood is *Barbara*, this being the only mood which is capable of proving A. Further, this is the only figure in which the minor term is the subject of the minor premiss, and the major term the predicate of the major premiss.

Fig. 2. Only a negative conclusion can be established in this figure, for the middle term is the predicate in both premisses, one of which must consequently be negative, to avoid undistributed middle; and one premiss being negative, the conclusion must be negative also by Rule 6.

Fig. 3. In this figure, only *particular* conclusions can be established.

Fig. 4. This figure is somewhat unnatural and is seldom used; it is, in fact, rejected by some logicians.

Lambert, a logician of the eighteenth century, thus described the four figures: "The first figure is suited to the discovery or proof of the properties of a thing; the second to the discovery or proof of the distinction between things; the third to the discovery or proof of instances and exceptions; the fourth to the discovery or exclusion of the different species of a genus."

Résumé of Chapter XVII.

I. *Reduction.*

1. Definitions—
   a. Reduction is the process of changing a syllogism from any mood and figure in which it may be into another mood or figure. Reduction is usually into Fig. 1 from another figure.
   b. *Reductio per impossibile* is a method of proving the conclusion of a syllogism, by showing that a denial of its truth results in a contradiction of one of the premisses.
2. All moods are reducible to Fig. 1 by conversion and transposition, except *Baroco* and *Bocardo*.
3. *Baroco* and *Bocardo* are reducible to Fig. 1 by the help of contraposition and obversion. They may be proved by *reductio per impossibile*.
4. Explanation of *s*, *m*, and *p* in the mnemonic lines.
   a. The letter *s* means *simply convert* the proposition denoted by the preceding vowel.
   b. The letter *m* means *interchange* the premisses.
   c. The letter *p* means *convert per accidens* the proposition denoted by the previous vowel.

II. Characteristics of the figures—

1. Fig. 1 proves A, E, I, and O.
2. Fig. 2 proves only negative conclusions.
3. Fig. 3 proves only particular conclusions.
4. Fig. 4 is unnatural and little used.

Exercises on Chapter XVII.

1. Which figure is of the greatest importance? Why?

2. How is Aristotle's *dictum de omni et nullo* connected with the subject of reduction.

3. What is *Reduction*.

4. Explain all the significant letters in the mnemonic lines.

5. Reduce *Darapti*, *Disamis*, *Datisi*, *Felapton*, and *Ferison*.

6. Reduce *Baroco* and *Bocardo*.

7. Prove *Baroco* and *Bocardo* by *reductio per impossibile*.

8. Why are the premisses of *Fesapo* and *Fresison* not transposed in reduction, like those of the other moods of the fourth figure?

CHAPTER XVIII.

Irregular Syllogisms.

Except in books on Logic one rarely meets with reasoning arranged in strict syllogistic form. This arises from various causes. Sometimes from the desire to be as concise as possible, and sometimes out of compliment to our hearers, we omit one of the premisses, taking it for granted that such premiss is well known to them. Sometimes, too, a premiss is omitted because it is not explicitly present as such to our own minds.

If we say:—*This is valuable, for it is gold*, we are reasoning syllogistically, but the syllogism is not fully expressed. In full our argument would stand—

All gold is valuable,
This is gold,
therefore *This is valuable.*

This is a syllogism of the mood *Barbara* in Fig. 1. The major premiss, *All gold is valuable,* is omitted from the expression of the syllogism in its first form, it being assumed that every one is well aware of the truth of what it asserts.

Such a syllogism is no violation of the rule that every syllogism consists of *three* propositions, for it does in reality consist of three propositions, though only two of these are expressed.

A syllogism in which one proposition is left unexpressed is called an *enthymeme*. An enthymeme is said to be of the *first*, *second*, or *third* order, according as the *major* premiss, the *minor* premiss, or the *conclusion*, respectively, is left unexpressed.

Thus, *he is honest, for he is an Englishman*, is an enthymeme of the *first* order, the unexpressed premiss being the *major*, viz.—

All Englishmen are honest.

An enthymeme of the *second* order is—

He is honest, for all Englishmen are honest,

the minor premiss, *he is an Englishman*, being implied, but left unexpressed.

The conclusion is less frequently omitted, but its omission is of frequent occurrence in witty sayings, the wit often consisting in making the conclusion so evident that it must be drawn by the hearer, and yet leaving it unexpressed.

All Englishmen are honest, and he is an Englishman,

is an enthymeme of the *third* order. The wonderful speech of Mark Antony over Cæsar's body (see *Julius Cæsar*, Act. III, scene 2) contains many enthymemes of the *third* order.

It should be carefully noticed that a fallacy is much more likely to escape detection in an enthymeme than in a fully-expressed syllogism. In testing an enthymeme, of course, the missing premiss must be supplied and the complete syllogism tested.

We not infrequently meet with trains of reasoning in which there is apparently but one conclusion drawn from many premisses. Thus, we may have such a train of reasoning as this—

All A's are B,
All B's are C,
All C's are D,
All D's are E,
therefore All A's are E.

This is in reality a number of connected syllogisms, all of which, except the last, are enthymemes of the third order. Such a series of syllogisms is known as a *sorites*, which means literally, a *heap* of syllogisms.

If we analyse the above we obtain the syllogisms—

1. All A's are B; All B's are C; therefore All A's are C.
2. All A's are C; All C's are D; therefore All A's are D.
3. All A's are D; All D's are E; therefore All A's are E.

The above is an example of the *ordinary* or *Aristotelian sorites*. In forming such a *sorites*, two rules should be observed—

1. *Only one premiss* (*the first*) *can be particular.*
2. *Only one premiss* (*the last*) *can be negative.*

It will form a useful exercise for the student to find out the reason for these rules.

It is possible to form a *sorites* having its premisses in the reverse order of the above, thus—

All D's are E,
All C's are D,
All B's are C,
All A's are B,
therefore All A's are E.

This is called the *Goclenian sorites*, after the name of Goclenius, a German philosopher (A.D. 1547 to 1628), who first enunciated it.

The special rules for the *Goclenian sorites* are—

1. *Only one premiss* (*the first*) *can be negative.*
2. *Only one premiss* (*the last*) *can be particular.*

The student can, by analysing any example of the *Goclenian sorites* into its consistent syllogisms, easily discover the reasons for these rules.

The above example of the ordinary *sorites* consists, as we have seen, of three simple syllogisms, the conclusion of the first being a premiss of the second, and the conclusion of the second a premiss of the third.

A syllogism, the conclusion of which stands as a premiss in another syllogism, is called a *prosyllogism*, and the one in which such conclusion is a premiss is called an *episyllogism*.

Thus the syllogism—

All A's are B,
All B's are C,
therefore All A's are C,

is a prosyllogism to—

All A's are C,
All C's are D,
therefore All A's are D,

which is an episyllogism with reference to the preceding prosyllogism.

Résumé of Chapter XVIII.

I. An *enthymeme* is an incompletely expressed syllogism.

1. An *enthymeme of the first order* is a syllogism having its major premiss unexpressed.
2. An *enthymeme of the second order* is a syllogism with an unexpressed minor premiss.
3. An *enthymeme of the third order* is a syllogism with an unexpressed conclusion.

II. *Sorites* is a number of syllogisms joined in a series.

1. Ordinary or Aristotle's sorites has the premiss which contains the subject of the conclusion stated first.
2. The Goclenian sorites has the premiss which contains the predicate of the conclusion stated first.

III. A *prosyllogism* is a syllogism, the conclusion of which is a premiss to another syllogism, this latter being called an *episyllogism*.

Exercises on Chapter XVIII.

1. Give two concrete examples of each order of enthymeme.
2. Analyse the following ordinary sorites into its constituent syllogisms—

I am a hard-working student,
All hard-working students pass their examinations,
All who pass their examinations gain good appointments,
All who gain good appointments have good incomes,
therefore
I shall have a good income.

3. Write the ordinary sorites in Question 2 in the form of the Goclenian sorites.
4. Why can the ordinary sorites have only one premiss, and that the first, particular?
5. Explain *prosyllogism* and *episyllogism*.
6. Why, in the Goclenian sorites, can there be only one premiss, and that the first, negative?

CHAPTER XIX.

Mixed Syllogism.

In all the syllogisms so far discussed, the premisses have both been *categorical* propositions. Syllogisms are frequently met with, however, in which one premiss is a *hypothetical* proposition, as also are those in which one premiss is a disjunctive proposition. Such syllogisms are generally called mixed syllogisms. A hypothetical proposition consists of two parts, the *antecedent* and the *consequent*. The antecedent is the part which states the condition, and is introduced usually by the word *if*, but not infrequently by other equivalent words or phrases, such as—*provided that*, *whenever*, *given that*, *granted that*, etc.; the consequent is the part of the hypothetical proposition which contains the statement made under the condition given in the antecedent. Thus, *if he studies, he will pass his examination*, is a hypothetical proposition, of which *if he studies* is the antecedent, and *he will pass his examination* is the consequent.

Since the truth of the consequent follows from the truth of the antecedent, it is clear that, in *thought*, the antecedent precedes the consequent; in *expression*, however, the consequent almost as frequently as not precedes the antecedent. There is no difference in meaning between—

If the temperature falls it will freeze,

and, *It will freeze if the temperature falls.*

The order *antecedent—consequent*, is the strictly logical order, and this order should be preserved in dealing with mixed syllogisms containing a hypothetical premiss.

The *mixed hypothetical syllogism* may be defined as a syllogism having for its major premiss a hypothetical proposition and for its minor premiss a categorical proposition: *e.g.*—

If it thundered, it lightened (hypothetical major)
But it did thunder, (categorical minor)
therefore, *It lightened.*

Since the minor premiss may affirm or deny the antecedent or the consequent of the hypothetical major premiss we have four *possible* types of mixed hypothetical syllogisms. The premisses of these may be represented in symbols thus:—

1. If A is B, C is D,
   But A is B.
2. If A is B, C is D,
   But A is not B.
3. If A is B, C is D,
   But C is D.
4. If A is B, C is D,
   But C is not D.

Now the question arises which of these four pairs of premisses will give a valid conclusion? It is easy to see that the first pair of premisses justify the conclusion *C is D*. Consider a concrete example of the same form, *e.g.*—

If this is bread, it is good to eat,
But it is bread,
therefore It is good to eat.

This is clearly true whenever the premisses are true; for if not we should have a conclusion, *it is not good to eat*, which with the minor premiss, *it is bread*, contradicts the

major premiss ; that is, it is possible to allow the truth of the major and minor premiss and deny the truth of the conclusion only by falling into contradiction. Hence, Case 1 gives a valid conclusion.

Take a concrete example of the form of the second pair of premisses, *e.g.*—

If this is bread, it is good to eat ;
But it is not bread.

This, clearly, will not give us the conclusion—

It is not good to eat,

for there are many things good to eat other than bread, and it may be one of these. The conclusion, *it is good to eat*, would be consistent with the premisses, as well as the conclusion, *it is not good to eat.*

Hence no conclusion can be drawn.

Consider the third case, of which this is a concrete example—

If this is bread, it is good to eat ;
But it is good to eat.

If any conclusion follows it must be—

It is bread.

But this does not follow, for it may be something other than bread and still be good to eat, in which case our premisses would be true and the conclusion, *it is bread*, false. The conclusion is, therefore, invalid.

This is a concrete example of the fourth type—

If this is bread, it is good to eat.
But it is not good to eat.

If these premisses give a conclusion it evidently is—

therefore *It is not bread.*

The premisses do justify this conclusion ; for if not, then the premisses can be true and the conclusion false. Assume such a case. Then, the conclusion being false, *it is bread*

must be true. From this and the major premiss, it follows (by Case 1) that *it is good to eat*, and this contradicts the minor. Hence, if the conclusion be not true, we fall into contradiction. Therefore, the conclusion, *it is not bread*, is a valid inference from the premisses.

Case 1, in which the minor premiss affirms the antecedent of the major, and Case 4, in which the minor denies the consequent of the major premiss, give valid conclusions, and they are the only ones which do so. Hence, we may use, as a test of the validity of mixed hypothetical syllogisms, the rule: *In mixed hypothetical syllogisms, either the antecedent must be affirmed, or the consequent denied.*

A syllogism, in which the minor denies the antecedent of the major premiss, contains the *fallacy of denying the antecedent*, as it is called; and a syllogism, the minor premiss of which asserts the truth of the consequent, contains what is called the *fallacy of affirming the consequent.*

Mixed hypothetical syllogisms can always be reduced to the form of a categorical syllogism, and can then be tested by the syllogistic rules. The first case considered above is equivalent to—

All things which are bread are good to eat,
This is bread,
therefore This is good to eat.

This is *Barbara* in Fig. 1.

The second case is equivalent to—

All things which are bread are good to eat,
This is not bread,
therefore This is not good to eat,

a syllogism containing the fallacy of the *illicit process of the major term*, of which the fallacy of *denying the antecedent* is the equivalent.

Case 3 in categorical form—

All things which are bread are good to eat,
This is good to eat,
therefore This is bread.

In this there is the fallacy of the *undistributed middle term*, of which the fallacy of affirming the consequent may be regarded as the equivalent.

In the mixed disjunctive syllogism, the major premiss is a disjunctive proposition (see Chapter VIII.), and the minor premiss a categorical proposition. There are two forms which may be written thus :—

1. A is either B or C,
But A is B,
therefore A is not C.

} This is called the *modus ponendo tollens.*

2. A is either B or C,
But A is not B,
therefore A is C.

} This is called the *modus tollendo ponens.*

The name given to the first, *modus ponendo tollens*, means, literally, the *mood which by affirming denies*, and although awkward, is appropriate enough, since in this, a minor premiss which *affirms* is followed by a conclusion which *denies*. The name given to the second form, *modus tollendo ponens*, means the *mood which by denying affirms*, and was given to this form because in it the minor which *denies* is followed by a conclusion which *affirms*.

The *modus ponendo tollens* is valid only if the disjunctives are mutually exclusive. Thus, *honesty* and *roguery* being mutually exclusive, the disjunctive syllogism—

A. B. is either an honest man or a rogue,
He is an honest man,
therefore He is not a rogue,

which is a case of the *modus ponendo tollens*, is valid. The case is different, however, with the following syllogism, which is of the same form—

He is either knave or fool,
He is a knave,
therefore He is not a fool.

In this, the conclusion is invalid, for he may be both knave and fool, *knavery* and *foolishness* not being mutually exclusive.

The *modus tollendo ponens* is always valid, whether the alternatives are mutually exclusive or not Thus, if we know that—

A. B. is either a soldier or a sailor,

and are further told that—

He is not a soldier,

we know certainly that—

He is a sailor.

Résumé of Chapter XIX.

Mixed Syllogisms.

I. Mixed hypothetical syllogisms are those having a hypothetical major and a categorical minor premiss.

1. Rule.—*Either the antecedent must be affirmed or the consequent denied.*
2. Types—
   a. If A is B, C is D ; but A is B, therefore, C is D. —Valid.

b. If A is B, C is D ; but A is not B, therefore, C is not D. Invalid—commits the *fallacy of denying the antecedent.*

c. If A is B, C is D ; but C is D, therefore, A is B. Invalid—committing the fallacy of *affirming the consequent.*

d. If A is B, C is D ; but C is not D ; therefore, A is not B. Valid.

3. All mixed hypothetical syllogisms are reducible to the categorical form. By this reduction—

a. The fallacy of denying the antecedent becomes the *illicit process of the major term.*

b. The fallacy of affirming the consequent becomes the fallacy of the *undistributed middle term.*

II. Mixed disjunctive syllogisms are those in which the major premiss is a *disjunctive* and the minor a categorical proposition. There are two types—

1. The *modus ponendo tollens*, having an affirmative minor premiss and a negative conclusion. This is valid only when the disjunctives are mutually exclusive.

2. The *modus tollendo ponens*, having a negative minor premiss and an affirmative conclusion. This is always valid.

Exercises on Chapter XIX.

1. Explain *hypothetical proposition, antecedent, consequent.*
2. Test the arguments—
   a. If that plant is the deadly nightshade, it is poisonous.
   It is the deadly nightshade,
   therefore, It is poisonous.
   b. If he is guilty he will be hanged,
   But he is not guilty,
   therefore, He will not be hanged.
   c. If he is guilty he will be hanged,
   He will be hanged,
   therefore, He is guilty.
3. Reduce the syllogisms in Question 2 to the categorical form and test them by the syllogistic rules.
4. Explain carefully why *A is B* is not a valid inference from the premisses—
   If A is B, C is D,
   But C is D.
5. Is the following a valid argument ?—
   If there were no dew the weather will be foul,
   But there was dew,
   therefore, The weather will be fine.
6. What kind of argument is this—
   I cannot dig ; to beg I am ashamed.
7. Test—
   We shall have a tempest, for it is very warm.
8. Put the following argument into the form of a mixed hypothetical syllogism, and test it—
   "Since the laws allow everything that is innocent, and avarice is allowed, it is innocent."—(*London University.*)

CHAPTER XX.

The Dilemma.

There is still one kind of syllogism which we have not yet explained and which deserves explanation, if for no other reason than this, that its name is a word often used and frequently with no very clear idea of its meaning. It is the *dilemma*.

The dilemma is a syllogism in which the *major* premiss is a *compound hypothetical* proposition, and the *minor* premiss a *disjunctive* proposition. In accordance with the definition we shall obtain four types, as is clear from the following examples—

1. If A is B, C is D; and if E is F, C is D
   (compound hypothetical major premiss),
   But either A is B or E is F
   (disjunctive minor premiss),
   therefore C is D.
2. If A is B, C is D; and if A is B, E is F
   (compound hypothetical major),
   But either C is not D or E is not F
   (disjunctive minor),
   therefore A is not B.
3. If A is B, C is D; and if E is F, G is H
   (compound hypothetical major),
   But either A is B or E is F
   (disjunctive minor),
   therefore either C is D or G is H.

4. If A is B, C is D; and if E is F, G is H
(compound hypothetical major),
But either C is not D or G is not H
(disjunctive minor),
therefore either A is not B or E is not F.

In Example 1, it will be seen that the major premiss has two *antecedents*, but only one *consequent*. To obtain a valid conclusion in accordance with the rules for mixed hypothetical syllogisms, the minor must affirm the antecedent or deny the consequent. It cannot deny the consequent, for, if it did, it would be categorical, and the argument would not be a *dilemma*; the disjunctive affirmation of the two antecedents of the major premiss gives the necessary disjunctive minor.

Dilemmas with *affirmative* conclusions are called *constructive*, those with *negative* conclusions *destructive*; those with *categorical* conclusions are said to be *simple*, and those with *disjunctive* conclusions *complex*. Hence the first example is a *simple constructive* dilemma.

In Example 2, there is but one antecedent and two consequents in the major premiss, hence the only possible way to obtain a disjunctive minor premiss is to disjunctively deny the consequent. We thus obtain a categorical conclusion. This is the *simple destructive* dilemma.

In Example 3, the major premiss contains two antecedents and two consequents. Hence we can with this major premiss obtain two disjunctive minor premisses, for we may have as a minor premiss either the disjunctive affirmation of antecedent which gives Example 3, or the disjunctive denial of the consequent, which gives Example 4. Clearly, in both Examples 3 and 4, we must have a disjunctive conclusion.

Example 3 is known as the *complex constructive* dilemma, and Example 4 the *complex destructive* dilemma. The following table shows the principle on which dilemmas are named.

			Dilemma.
Conclusion.	I. Categorical	1. Affirmative	Simple constructive
		2. Negative	Simple destructive
	II. Disjunctive	3. Affirmative	Complex constructive
		4. Negative.	Complex destructive.

The following are concrete examples of the four kinds of dilemmas—

1. *Simple constructive dilemma.*—A cowardly soldier before battle, might argue:—If I run away I shall be killed for deserting the ranks, and if I stay I shall be killed in battle; therefore, in either case, I am sure to be killed.
2. *Simple destructive dilemma.*—If that ship catches the trade winds, it will have a short and prosperous voyage; but its voyage either will not be short or will not be prosperous: therefore, it will not catch the trade winds.
3. *Complex constructive dilemma.* — If a man is rich he is troubled by the care of his riches, and if he is poor he is anxious to obtain wealth; but either he is rich or poor: therefore, he is either troubled or anxious.
4. *Complex destructive dilemma.*—If our education improves, our commerce will increase, and if we have an efficient navy our commerce will be safe; but either our commerce is not increasing, or it is not safe; therefore, either our education is not improving or we have not an efficient navy.

The characteristic feature of the dilemma is that it allows a choice of two alternatives. In practice, the dilemma is

generally so contrived that, of the two alternatives, one must be accepted, although both are so disagreeable that the opponent would willingly reject both if possible. It is this difficulty of making a choice between equally unpleasant alternatives that is called *being on the horns of a dilemma*.

When a dilemmatic argument offers three alternatives, it is called a *Trilemma;* when four a *Tetralemma*, and when more than four a *Polylemma*.

The best way of escaping from "the horns of a dilemma" is to frame another, such that its conclusion contradicts the conclusion of the original dilemma and is equally evident. This is called *rebutting* the dilemma.

A very old example of a dilemma, and the way in which it may be rebutted, is the following:—

An Athenian mother said to her son:—"Do not enter public life, my son, for if you do and act justly men will hate you, and if in public life you act unjustly the gods will hate you!" The son replied "I will enter public life, for if in it I act justly the gods will love me, and if unjustly men will love me."

It will be seen in this case that the mother in the major premiss of her dilemma gives a one-sided view of the truth and that the apparent cogency of the conclusion depends upon a partial suppression of the truth. It is not the whole truth that her son will be hated by the gods if he acts unjustly. To give the whole truth she should have added, *but loved by men*: so his gaining the hate of men is only the partial consequence of his acting justly, for he will by so doing gain the love of the gods. The flaw in a dilemmatic argument should always be looked for in the major premiss.

Résumé of Chapter XX.

I. Definitions—
   1. *Dilemma.*—A syllogism with a compound hypothetical major and a disjunctive minor premiss. The dilemma offers two alternatives.
   2. *Trilemma.*—A dilemmatic argument offering three alternatives.
   3. *Tetralemma.*—A dilemmatic argument offering four alternatives.
   4. *Polylemma.*—A dilemmatic argument offering more than four alternatives.

II. Kinds of dilemmas—
   1. *Simple constructive*, having a *categorical affirmative* conclusion.
   2. *Simple destructive*, having a *categorical negative* conclusion.
   3. *Complex constructive*, having a *disjunctive affirmative* conclusion.
   4. *Complex destructive*, having a *disjunctive negative* conclusion.

III. To *rebut* a dilemma is to frame another dilemma having a contradictory but equally cogent conclusion.

Exercises on Chapter XX.

1. What is a dilemma? Can a dilemma offer more than two alternatives?
2. Give a symbolic and a material example of the *simple constructive dilemma.*

3. When is a dilemma said to be *destructive*? Give an example.

4. What kind of argument is this? Is it valid?

   All existences are either mental or material; nothing is neither mental nor material; therefore nothing is not an existence. (Dr. Ray's *Logic*.)

5. What is meant by *rebutting a dilemma?*

   Rebut:—If virtue were a habit worth acquiring, it must insure either power, or wealth, or honour, or pleasure; but virtue insures none of these; therefore, virtue is not a habit worth acquiring.

6. An old dilemma is the following:—

   Protagoras teaches Euathlus rhetoric for a certain fee, half to be paid at once, and the other half when Euathlus wins his first law case. Euathlus undertaking no case, is sued for the remainder of the fee, and is confronted by Protagoras with this dilemma. "You must pay this fee, for if you lose this case you will have to pay me by order of the court, and if you gain it you must pay me in accordance with our agreement, for then you will have won your first case."

   Can this be rebutted?

CHAPTER XXI.

Fallacies.

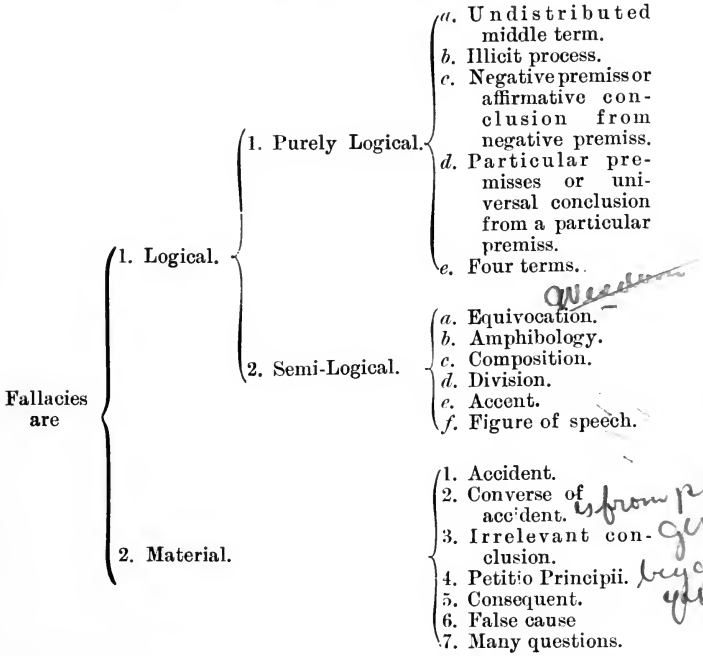
We have already had many cases of conclusions which were not justified by the premisses from which such conclusions were drawn. In all such cases a *fallacy* is said to be committed.

A *fallacy* may be defined as "any unsound mode of arguing, which appears to demand our conviction, and to be decisive of the question in hand, when in fairness it is not."

Since Logic treats of the principles of *valid* reasoning, it may at first appear strange to the student that text books of Logic always include a section on invalid forms of reasoning. It is, however, clear, that a knowledge of the commonest forms of invalid reasoning must be of great service in the effort to avoid invalid reasoning. It is an old and true saying that "the knowledge of contraries is the same." *Valid* and *invalid* reasoning may be regarded as relative terms, a knowledge of either involving a knowledge of the other. The rules of the syllogism are as much rules for avoiding invalid reasoning as they are for reasoning validly. Hence, in treating of *valid* reasoning, we necessarily at the same time, more or less, fully treat of *invalid* reasoning, and the fallacy committed in violating any rule of Logic is, perhaps, best discussed when such rule

is under consideration. It is, however, convenient to bring the various fallacies together into one section and treat of them together. Various attempts have been made to classify fallacies, none of which are entirely satisfactory. The simplest classification is Whately's, and his is a mere modification of Aristotle's. He first divided fallacies into those in the form of expression *(fallacies in dictione)*, and those in the *matter (fallacies extra dictionem)*. The fallacies in the form of expression he called *logical fallacies*. In the case of a logical fallacy the conclusion does not follow validly from the premisses : such fallacy can be detected by the mere logician without any knowledge of the subject matter of the argument. The fallacies in the matter or *material* fallacies are those arguments in which the conclusion does follow from the premisses, but yet is fallacious owing to some fault in the premisses. Such fallacies cannot be detected by the mere logician ; for their detection a knowledge of the subject matter of the argument is needed. Material fallacy is in Whately's classification a *species infima*. He enumerates seven individual fallacies of this class. *Logical fallacy* is further divided into the two species—*purely logical fallacy* and *semi-logical fallacy*. A purely logical fallacy is a violation of any of the rules of the syllogism except the second part of Rule 3 ; a semi-logical fallacy is a violation of the second part of the third rule, or less frequently an ambiguous use of the major or minor term.

The following table shows these classes and the individuals constituting the *species infima*—



The purely logical fallacies have been already discussed, in connection with the rules of the syllogism.

The semi-logical fallacies are nearly all cases of the ambiguous middle term. The rules of the syllogism enable us to tell that there is a fallacy as soon as we know the middle term is ambiguous; but to detect what the ambiguity is is impossible without a knowledge of the subject matter of the argument, hence the name *semi-logical* applied to these fallacies. We proceed to explain each of the semi-logical fallacies. The student should carefully

notice that the names given to the various fallacies are technical terms, and as such have a definite connotation which may differ from the meaning ordinarily attributed to them when used in common parlance.

By *equivocation* is meant the fallacy arising from the use of a term in two different senses in the same argument. This is, perhaps, the commonest of all fallacies, and is frequently very difficult to detect. The examples of ambiguous middle already discussed are cases of *equivocation*. Here is another example—

The end of life is the highest good,
Death is the end of life,
therefore Death is the highest good.

In this argument the middle term, *the end of life*, is used in different senses in the two premisses; in the major premiss it means the *object to be aimed at in life*, but in the minor premiss it means the *cessation of vital action*.

Another example is—

To call you an animal is to speak the truth,
To call you an ass is to call you an animal,
therefore To call you an ass is to speak the truth.

That there is a fallacy in this is evident, but what that fallacy is is not so apparent. The student may exercise himself in explaining it.

Amphibology is a fallacy arising from a loose grammatical structure. Many examples of this fallacy may be culled from newspaper advertisement columns. Here are two examples:—"A piano for sale by a lady about to cross the channel in oak case with carved legs."—"For sale—a large retriever; will eat anything, very fond of children."

Fallacies such as these may raise a laugh, but can scarcely mislead anyone. This is not, however, always the

case with fallacies of *amphibology*. It is impossible to tell from the words alone whether *twice two and three* are *seven* or *ten*.

Occasionally it is difficult or impossible to distinguish the subject from the predicate in a proposition. The Latin language is peculiarly liable to this ambiguity, and it is therefore, a language specially suited for giving oracular answers to replies about the future, answers which are sure to be right, however the event may turn out. If translated into English the ambiguity often disappears. A well-known example is—

Aio te Romanos vincere posse,

that is, in English—

I say that you the Romans can conquer.

Two good examples of (intentional) amphibology occur in Shakespeare. One of these occurs in *Henry VI.*, where it is said—

"The Duke yet lives that Henry shall depose,"

and the other in *Richard II.*, where York says—

"He loves you on my life and holds you dear,
As Harry, Duke of Hereford, were he here."

Let the student try to grammatically parse the words in these two cases and he will at once detect the ambiguity.

The fallacy of *composition* is that particular case of ambiguity of a term in which in one case of its occurrence the term is used in a *distributive* sense, and in the other in a *collective* sense. Thus, if we argue—

All the angles of a triangle are less than two right angles,
A, B, C, are all the angles of a triangle,
therefore
A, B, C, are less than two right angles,
we commit the fallacy of composition.

Other examples are—

A cannot lift this box, B cannot lift it,
therefore A and B cannot lift it.

I can afford to buy all I want, for I can afford to buy A, I can afford to buy B, I can afford to buy C, and A, B, C are all I want.

The fallacy of *divisiom* is the converse of the fallacy of composition. It arises from first using a term in a *collective* sense and assuming that what is true of it in that sense, is also true of it when used in a distributive sense, *e.g.*—

A can sing a duet,
B can sing a duet,
for A and B can sing a duet.

All the angles of a triangle are equal to two right angles,
A is one of the angles of a triangle,
therefore A is equal to two right angles.

The fallacy of *accent* arises whenever greater importance is attributed to any word than is warranted by the context or was intended by the writer or speaker. In the First Book of Kings (Chapter XIII., v. 27), occur the words:—"And he spake to his sons, saying, 'Saddle me the ass.' And they saddled *him*". If in reading this passage the word "him" be strongly accented, as the fact of its being italicised might suggest it should be, we fall into the fallacy of accent, for we suggest a meaning to the word evidently different from that intended to be expressed by it. The translators of our Authorised Version of the Bible had words printed in italics to denote that words so printed had no corresponding words in the original Hebrew text; hence, in the Bible, italics do not denote special accent, but rather an absence of any accent at all.

It is an example of this fallacy: "when the country parson reads out, 'Thou shalt not bear false witness *against* thy neighbour' with a strong emphasis on the word 'against', his ignorant audience leap to the conclusion that it is not amiss to tell lies provided they be in favour of one's neighbour".*

Almost any sentence can be made to convey as many meanings as it contains words by emphasising each word in turn. Fallacies may, and often do, arise from taking for granted that words derived from the same root have corresponding meanings. Thus, it might be thought that he who tells a *lie* is a *liar*. This is not, however, necessarily so, for the word *liar* implies the *habit* of lying. Similarly, it is possible to *thieve*, without being a *thief*, to *drink* without being a *drunkard*, to follow a *craft* without being *crafty*, and so on. Fallacies arising from this cause are known as *fallacies of figure of speech*, or *fallacies of paronymous terms*.

A good example is—

Projectors are unfit to be trusted,
This man has formed a project,
therefore, This man is unfit to be trusted.

Mrs. Malaprop falls into this fallacy when she says she would have her daughter *artful*. Another example may be quoted from Shakespeare's *Richard II.*

Bolingbroke. Go, some of you convey him to the tower.
King Richard. O, good, convey? Conveyors are you all,
That rise thus nimbly by a true king's fall.

The word "conveyor" in Elizabethan English meant a *thief*.

* St. George Stock's *Logic*.

Résumé of Chapter XXI.

I. Fallacy. Any unsound mode of arguing which appears to demand our conviction and to be decisive of the question in hand when in fairness it is not.

II. Fallacies are—

I. Logical. Subdivided into

a. Purely Logical.
1. Undistributed middle.
2. Illicit process.
3. Negative premisses or affirmative conclusion where one premiss is negative.
4. Particular premisses or universal conclusion with one premiss particular.
5. Four terms.

b. Semi-Logical.
1. Equivocation.
2. Amphibology.
3. Composition.
4. Division.
5. Accent.
6. Figure of speech.

2. Material Fallacies (*See Résumé of Chapter XXII.*)

III. Definitions—

1. *Equivocation* is the use of one term in two senses in the same argument.
2. *Amphibology*, an ambiguity due to a faulty grammatical structure.
3. *Composition*, fallacy arising from a confusion of the *collective* and *distributive* use of a term.
4. *Division*, the converse of composition—a fallacy arising from a confusion of the *distributive* and *collective* use of a term.

5. *Accent*, a fallacy which consists in attributing to a word greater importance than it is intended to have.
6. *Figure of speech*, or the *fallacy of paronymous terms*, the fallacy which arises from assuming that words from the same root have corresponding meanings.

Exercises on Chapter XXI.

1. Give an example of the fallacy of *equivocation*.
2. Explain and illustrate the fallacy of *composition*.
3. Explain the distinction between fallacies *in dictione* and fallacies *extra dictionem*.
4. What fallacies (if any) are committed in the following arguments ?
   a. Water is blue, this is a glass of water, therefore it is blue.
   b. To be acquainted with the guilty is a presumption of guilt. This man is acquainted with the guilty ; therefore we may presume that he is guilty.
   c. Five is one number. Three and two are five ; therefore three and two are one number.
   d. All the metals conduct heat and electricity, for iron, lead, and copper do so, and they are all metals.
   e. If there is a demand for education, compulsion is unnecessary.
   f. A man will become strong by drinking brandy, for brandy is a strong drink.

g. When Crœsus has the Halys crossed,
A mighty army will be lost.

h. Justice is the profit of others, therefore it is unprofitable to the just man to be just.

i. "Is a stone a body"? "Yes". "Well, is not an animal a body"? "Yes". "And are you an animal"? "It seems so". "Then you are a stone, being an animal".

CHAPTER XXII.

Material Fallacies.

The fallacies *extra dictionem*, or material fallacies, are, as we have seen—

1. The fallacy of accident.
2. The converse fallacy of accident.
3. The fallacy of the irrelevant conclusion.
4. The fallacy of the *petitio principii*.
5. The fallacy of the consequent, more frequently called *non sequitur*.
6. The fallacy of the false cause.
7. The fallacy of many questions.

These we proceed to explain.

The fallacy of accident is committed whenever we argue that a statement which is true as a general rule is true also in a particular case in which the rule, owing to special circumstances or *accidental* conditions, does not hold. A very old example is—

What we buy in the market we eat;
We buy raw meat in the market;
therefore We eat raw meat.

In this the major premiss gives the general rule, which is true in regard to the *substance*, but the minor premiss introduces a case having the *accidental* condition of *rawness* added; and this condition makes the general rule inapplicable.

Again if we argue—

Gooseberries are eatable,
This is a gooseberry,
therefore This is eatable,

our reasoning is fallacious, unless we take care that the middle term *gooseberry* is used exactly in the same sense. If the particular gooseberry referred to in the minor premiss is *unripe*, this accidental circumstance, not being contemplated by the general rule, renders such rule inapplicable to this case.

If, however, under the same circumstances, we argue—

This is not eatable, and it is a gooseberry,
therefore, Gooseberries are not eatable,

we commit the *converse fallacy of accidents*, for we are arguing to a general rule from a particular case, which owing to the accidental circumstance of its not being ripe is not a typical example.

Another example of the converse fallacy of accident, is—
He who hurts another deserves punishment,
The teacher who punishes a refractory pupil hurts another, therefore, Such teacher should be punished.

In this, *he who hurts another* evidently means he who does so with *malicious intent*; hence, the major premiss makes the general statement *conditionally*, while the minor premiss uses the word *hurts* unconditionally.

This fallacy is often called *fallacia a dicto secundum quid ad dictum simpliciter* (the fallacy of making an unconditional assertion on the ground of an assertion made conditionally). This name should be remembered, although it is such a clumsy one, for it is the name of a very common fallacy.

Sometimes the fallacy of *accident* is called *fallacia a dicto simpliciter ad dictum secundum quid.* (Fallacy of arguing from an unconditional premiss to a conditional conclusion).

It is not always clear whether a fallacy is better explained as a case of the fallacy of accident or of its converse. Thus the fallacy in—

He who hurts another deserves punishment,
The teacher who punishes a refractory pupil hurts another,
therefore, Such teacher deserves punishment,

is explained as a case of the converse fallacy of accident. But if we choose to regard the word *hurts* in the major premiss as being used *unconditionally*, and in the minor premiss *conditionally* (the condition, *for the pupil's good*, being implied), we must regard it as an example of the fallacy of accident.

The fallacy of the *irrelevant conclusion* is often called the *ignoratio elenchi* (ignorance of the refutation). This consists in proving, instead of the proposition whose proof is required, another which is substituted for it. The argument in itself may be valid enough, but the conclusion is not to the point. There are teachers who argue that kindergarten methods are useless, for when children leave the kindergarten they are not so well advanced in reading, writing and arithmetic as they used to be before the introduction of kindergarten methods. But this is beside the point, for what has to be proved in order to establish the uselessness of kindergarten methods, is, that children, after going through the full kindergarten course, are no better trained than they were under the old system.

The street orator commits this fallacy when he dilates upon the great wealth of certain of the nobility, and then proceeds to take for granted that he has proved that such wealth should be distributed among his hearers. What is known as the *argumentum ad hominem* is a particular case of this fallacy. It consists in arguing upon any matter in

such a way that the conclusion reached is based on the character of those connected with it rather than on the merits or demerits of the case itself. If a man is known to be a thief, and is accused of a particular case of theft, it is a difficult matter to base our judgment as to whether he is guilty or not on the facts of the case, and not in any way allow ourselves to be influenced by our knowledge of such a man's character. In olden times, in trial by *Compurgation*,* this logical fallacy had a legal recognition. The only conclusion, however, logically valid, is one drawn *ad rem*, that is, one based on the facts of the case. Such a conclusion is the only one now recognised in English Law, according to which, at present, no evidence of previous crime is allowed until after the jury have given their verdict.

The *argumentum ad hominem* is not infrequently made use of in our Law Courts, where the counsel for the prosecution frequently tries to prejudice the jury against the prisoner by setting forth the heinousness of the crime of which he is accused, or by dilating upon the worthlessness of the prisoner's character.

The *argumentum ad populum* (argument with reference to a people) is of a similar nature, and consists in an appeal to the prejudices or passions of a people in order to warp their judgment.

The *petitio principii* consists in using the conclusion or its equivalent as a premiss from which such conclusion is drawn. It is often called *begging the proof*, and this aptly describes it. The fallacy is common, although it is difficult to give good *short* examples of it. This fallacy and the *ignoratio elenchi* are specially liable to occur in long

* See any History of England.

argumentative speeches, and being enveloped in a multitude of words are by no means always easy of detection. The teacher of mathematics knows how easy it is for students to beg the proof in working exercises in geometry. The fallacy may be illustrated symbolically thus—

The syllogism M is P,
S is M,
therefore S is P,

is valid if we grant the truth of the premisses; but if we proceed to establish the truth of the minor premiss thus—

P is M,
S is P,
therefore S is M,

we evidently assume the truth of "S is P" which is exactly what has to be proved. Whately gives a good instance of this fallacy. He says, "Some mechanicians attempt to prove (what they ought to have laid down as a probable but doubtful hypothesis) that every particle of matter gravitates equally. 'Why'? 'Because those bodies which contain more particles ever gravitate more strongly, *i.e.*, are heavier'. 'But' (it may be urged) 'those which are heaviest are not always the most bulky'. 'No, but still they contain more particles, though more closely condensed'. 'How do you know that'? 'Because they are heavier'. 'How does that prove it'? 'Because all particles of matter gravitating equally, that mass which is specifically the heavier must needs have the more of them in the same space'."

In falling into the fallacy of the *petitio principii*, we are said to be *arguing in a circle*. This should be compared with the *circle in defining*. (See Chapter XIII.)

The fallacy of the *consequent*, or *non sequitur* (it does not follow), as it is often called, consists in drawing a conclusion which has very little or no connection at all with the premisses. Thus, it is evidently a *non sequitur* to conclude that London is a beautiful city, because it is a great city, and all great cities contain great wealth. De Morgan gives as an example of this fallacy—

Episcopacy is of Scripture origin,
The Church of England is the only episcopal church in England,
ergo The church established is the church that should be supported.

The fallacy of the *false cause* is sometimes known as *non causa pro causa* (what is not the cause for the cause). A good example of this fallacy was supplied by Whitefield when he gave as the reason of his being overtaken by a hailstorm the fact that he had not preached at the last town. When one event precedes another we are very likely to take for granted that it is the cause of the phenomenon it precedes. That such a method of argument is wrong is clear, since by it we should have to conclude that night is the cause of day as it always precedes day. This fallacy is denoted by the phrase *post hoc ergo propter hoc* (after this, therefore on account of this). Sometimes what is merely a sign of a phenomenon is regarded as the cause of it, as if it were to be supposed a falling barometer is a *cause* of rain. Not infrequently the effect is regarded as the cause, as when it is thought that much money in a country is the cause of a country's wealth, when it is, in fact, the effect of such wealth.

The fallacy of *many questions* consists in asking, as one question, two requiring different answers, so that the

disputant, if he is allowed to give only categorical replies, commits himself whatever answer he gives. When the counsel for the prosecution says to the prisoner, "How long is it since you ceased to be a forger"? there is involved a fallacy of *many questions*. The question quietly takes for granted that the prisoner was a forger at one time.

A celebrated example of this fallacy is the question put by Charles II. to the then newly-established Royal Society. "Why," he asked, "when a live fish is put into a vessel of water, do the vessel, the water and the fish not weigh more than the basin and water before fish is put in, when if the fish be dead this is not the case"? The learned members of the Society are said to have discussed the question, and formed several hypotheses by way of explanation of such a curious fact. After a considerable time it was suggested by one member that they should try if such were really the case, and after much opposition the experiment was tried, and it was found out that the weight was the same whether the fish was living or dead.

Résumé of Chapter XXII.

Material Fallacies.

1. The *fallacy of accident* or *fallacia a dicto simpliciter ad dictum secundum quid*, is the application of a general rule to a particular case which, owing to special circumstances, does not conform to the rule.

2. The *converse fallacy of accident*, or *fallacia a dicto secundum quid ad dictum simpliciter*, is the proceeding to a general from a particular case, which, owing to special circumstances, is not a typical case.
3. The *irrelevant conclusion*, or *ignoratio elenchi*, is the proof of a truth other than the one required, and the further assumption that what was required has been done. The *argumentum ad hominem* is a frequent form of this fallacy.
4. The *petitio principii*, or *begging the question*, is the taking for granted in the course of the argument the very proposition whose truth is being established.
5. The *fallacy of the consequent*, or *non sequitur*, is the fallacy of drawing a conclusion from premisses with which it has little or no connection.
6. The *fallacy of false cause*, or *non causa pro causa*, is the regarding as cause what is not the cause.
7. The *fallacy of many questions* is the fallacy of asking two questions in one and expecting one categorical answer.

Exercises on Chapter XXII.

1. Give three examples of the fallacy of *accident*.
2. Explain what is meant by a *non sequitur*.
3. Explain the *argumentum ad hominem*.
4. Give an example of the fallacy *a dicto secundum quid ad dictum simpliciter*.

5. What fallacies are committed in the following arguments?

a. A designing man is to be suspected,
This man gains his living by designing,
therefore, He is to be suspected.

b. The verdict of the jury is seldom wrong,
A is a member of the jury,
therefore, His verdict is seldom wrong.

c. The wind blew a gale yesterday because the barometer was very low.

d. When will you become careful?

e. "Shall thine anger burn like fire for ever?"

f. Opium produces sleep because it possesses a soporific quality.

g. A certain Member of Parliament refused to vote for a bill because it was introduced by one who was a bad man.

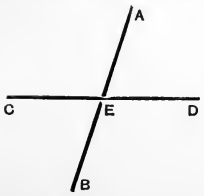
6. Examine the following:—

a. One number must win the prize,
My ticket is one number, and it will therefore win the prize.

b. All that glitters is not gold,
Tinsel glitters,
therefore, Tinsel is not gold. (Whately).

c. Nothing is heavier than platinum,
Feathers are heavier than nothing: therefore,
Feathers are heavier than platinum. (Whately).

Point out the *petitio* in the following:—



Given A B a straight line, and C E, D E two straight lines meeting A B in E, it is required to prove C E D a straight line.

By Euc. I. 15, angle C E B = angle A E D, and angle B E D = angle A E C.

Therefore angle C E B + angle B E D = angle A E D + angle A E C.

But all these angles are together equal to four right angles by Euc. I. 15 cor.

Therefore angles C E B, B E D are together equal to two right angles, and therefore by Euc. I. 14, C E D is a straight line.

CHAPTER XXIII.

Induction.

In this and the following chapters a few of the more important points, with regard to inductive reasoning, will be considered.

We have already seen (Chapter II.) that in an inductive argument the conclusion is more general than the premisses, that is, that the conclusion contains more knowledge than is contained in the premisses; but the premisses contain knowledge known before the inductive inference. Hence, in an inductive argument, we proceed from what is known to what is unknown. Induction has indeed been defined as *an inference from the known to the unknown.* Thus, when Shakespeare says "Murder will out" he is expressing an inductive inference. It had probably come within his experience many times, that murder had been discovered; this experience, together with what he had heard of the experiences of others, formed the premisses on which the general statement was based as an inductive inference.

This conclusion is clearly a much wider truth than all the premisses together, for it contains every case that has occurred since then, as well as every case that may occur in the future.

It is a curious fact that Aristotle, the great Greek philosopher, left Deductive Logic much as we have it now,

but left Inductive Logic in a very undeveloped state. Induction, as a science, was greatly advanced by Lord Bacon, but had to wait till the present century for anything like complete treatment. It first received full treatment at the hands of John Stuart Mill in his "System of Logic," which was published in A.D. 1843.

In an inductive argument there is always an extension of knowledge. How can we make sure that this extended knowledge is reliable ? That is the question that Inductive Logic endeavours to answer. It formulates methods to be followed and rules to be observed in the pursuit of knowledge by induction if we wish our conclusions to be real knowledge. As Deductive Logic treats of the rules which must be observed in drawing valid conclusions syllogistically, so Inductive Logic discusses the rules to be observed in drawing inductive inferences.

The necessity for such rules may be more clearly understood by considering two or three cases of invalid inductive inferences. Previous to the discovery of Australia one might have argued, as no doubt many people did, that *all* swans were white, because every swan hitherto seen by Europeans was white. Such conclusion was proved to be an invalid one by the finding of *black* swans in Australia. Again we might argue—

Italy is a peninsula pointing to the south,
Malaya is a peninsula pointing to the south,
South America is a peninsula pointing to the south,
And so on of many others,

therefore—

All peninsulas point to the south.

Such conclusion is, however, invalidated by such peninsulas as Jutland and Yucatan, which point to the north.

Induction, as exemplified in these two instances, in which the conclusion is based on a greater or less number of individual cases taken at random, is known as *inductio per enumerationem simplicem* (induction by means of a simple enumeration of instances).

This is what Aristotle understood by induction. It was ridiculed by Bacon as being a childish thing and giving utterly untrustworthy conclusions. Here is an instance of *inductio per enumerationem simplicem* as carried out by a child of six years of age: he came to the conclusion that no brightly-coloured flowers are scented, because he had noticed of tulips, snapdragons, pansies, and of several other brightly-coloured flowers that they have no scent. The invalidity of this conclusion is evident.

Bacon saw that a small number of well-selected instances were of far greater weight as evidence of the truth of the general statement than an almost infinite number of haphazard instances.

Does *inductio per enumerationem simplicem* ever give reliable conclusions? There are certain cases in which it gives knowledge as certain as human knowledge can be. In the first place, it gives such knowledge wherever the premisses embrace the uncontradicted experience of the human race. How do we know that an object if unsupported falls to the earth? or that man is mortal? By induction, moreover, an induction *per enumerationem simplicem.*

But the facts of experience on which the conclusion in each of these cases is based, are facts supplied by the uncontradicted experience of the whole human race. Very seldom, however, does it happen that we can make use of premisses so numerous as in these cases.

There is another case in which induction gives sure conclusions and which is intimately connected with induction in its origin. The word *induction* means etymologically a *bringing in—a bringing in* of what? The particular facts contained in the general assertion. For example, A and B are engaged in an argument in which A says "All planets go round the sun". B, however, will not accept this statement. What can A do? He straightway makes use of *induction* to prove his general assertion, by bringing in the particular facts contained in the general statement and trying to get B to allow them one by one.

A. Well, Mercury is a planet and goes round the sun. You allow that?

B. Yes.

A. Venus is also a planet and goes round the sun. Do you allow that?

B. Yes.

A. The earth is a planet and goes round the sun?

B. Yes.

How far must A proceed in his bringing in of the particular cases, before he can be considered to have proved his original assertion? If the conclusion be reached, after bringing in only a part of the cases contemplated in the general assertion, we have an induction *per enumerationem simplicem*, and therefore B will be justified in rejecting the conclusion as invalid.

But if A proceeds to bring in every case of a planet, and B allows, in each case, that it goes round the sun, B is then bound to allow the truth of the assertion "All planets go round the sun", for this is nothing but a short way of expressing all the truths which he has individually accepted. A is said to have completed, or *perfected*, his induction, and

the process is what is known as *perfect induction*. The name must not be understood as meaning that this is a better method of induction than ordinary induction. It merely means that the induction has been *completed*, which is the meaning of the Latin word *perfecta*.

If we take as our definition of induction that it is *inference from the known to the unknown*, it is clear that *perfect induction* is not induction at all. Thus, if I argue—

January has not 32 days,
February has not 32 days,
March has not 32 days,
April has not 32 days,
May has not 32 days,
June has not 32 days,
July has not 32 days,
August has not 32 days,
September has not 32 days,
October has not 32 days,
November has not 32 days,
December has not 32 days,
therefore No month in the year has 32 days,

the conclusion is exactly co-extensive with the premisses, and there is, therefore, no proceeding from *the known to the unknown*. Hence, there is no real induction (according to our definition) in the process. Of course, the term induction may be so defined as to make *perfect induction* one of its constituent species.

Résumé of Chapter XXIII.

I. *Induction* is inference from the known to the unknown.

II. *Inductio per enumerationem simplicem.*

1. Definition.—That form of induction in which the premisses are taken at random without any consideration of their relative value.
2. Reliability.—Reliable only when the premisses are co-extensive with the experience of the human race.

III. *Perfect Induction.*

1. Definition.—The summation of a number of premisses into the form of a general assertion.
2. It contains no inference, and is, therefore, not induction at all.
3. The conclusion is as sure as the premisses.

Exercises on Chapter XXIII.

1. Give three examples of induction.
2. Explain *inductio per enumerationem simplicem.*
3. Explain and give an example of *perfect induction.*
4. Why is *perfect induction* not induction at all.
5. What was the first use of induction ?
6. Why was *induction* developed later than *deduction* ?

CHAPTER XXIV.

Cause, Law of Nature, Explanation.

Much has been written as to the exact meaning of the word *cause*, and much that has been written belongs to the subject of metaphysics rather than the domain of Logic. It is one of the most frequently used of technical terms in science, and is generally used with a definite, clearly intelligible meaning. An example will make its meaning clear.

A storm rages at sea, and during the storm a vessel sinks. In such a case, we say the storm is the *cause* of the vessel sinking, and that the sinking of the vessel is an *effect* of the storm.

According to such use, the *cause* is evidently a phenomenon which precedes the effect, and in the absence of which the effect would not have happened. It should, however, be noticed that usually many causes concur in producing the effect. Thus, a person may die from a complication of ailments, any one of which may be spoken of as the *cause* of his death. Indeed, it seldom or never happens that a phenomenon is the effect of only one cause. In fact, philosophically speaking, all the antecedent conditions of which a phenomenon is the outcome are its cause. Amongst all the antecedent circumstances, however, one is singled out as the *cause*, the one so chosen

generally being the new circumstance immediately antecedent to the effect, or a circumstance to which the result specially directs our attention. Thus, if a man falls into a river and is drowned, there are many circumstances which, in combination, produce the effect, *e.g.*, the circumstances causing his fall (his going out in a boat, possibly) his inability to swim, the fact that his nature is such that he cannot exist under water, the depth of the water, etc. But we probably choose the new circumstance of his going out in a boat, or his inability to swim, a circumstance to which his death calls special attention, and look upon it as the *cause* of his death.

Cause may be defined, then, as "that new circumstance or those new circumstances which precede the given effect, and without which such effect would not occur".

"Anything in the absence of which a phenomenon would not have come to pass as it did come to pass is a cause in the ordinary sense."* Given an effect to discover its cause or causes is the main problem of induction.

"Happy is he who has been able to discover the causes of things,"† wrote the Roman poet Virgil nearly two thousand years ago, and his words express a psychological truth, for now, as in his time, one of the keenest of intellectual pleasures is the discovery of the causes of given effects. In seeking for causes, it is always taken for granted—

1. That every event has a cause.
2. That the same cause always produces the same effect.

The former of these two assumptions is what is known as the *Law of Causation*. It would clearly be fatal to investigation did we not think ourselves justified in assuming that

---

* Minto's *Logic*.

† Virgil's *Georgics*, II., 490.

the phenomenon in course of investigation has a cause, and therefore admits of explanation. It is really the assumption that no phenomenon is absolutely isolated from all other phenomena. Our knowledge of any phenomenon is in truth a knowledge of the relations between it and other phenomena. The second of the above two assumptions is what is known as the *Law of the Uniformity of Nature.* Any given natural cause produces the same effect to-day that it did a thousand years ago or that it will do a thousand years hence. It is only on this assumption and conditioned by it that science can foretell events. Thus, the astronomer foretells the exact time at which an eclipse of the moon or of the sun will occur, but he can do this only on the assumption that the course of nature will remain uniform. Should such uniformity cease the expected eclipse may not occur.

On what grounds do we rely for our belief in such uniformity of nature? It is a truth established by *inductio per enumerationem simplicem*, which in this case gives knowledge as certain as any knowledge possible to man, for it is the foundation of all knowledge. The simple enumeration is, however, an enumeration of facts in accordance with the unvarying experience of the whole human race.

The student is now in a position to understand clearly the meaning of the term *law* as used in science. A *law* of nature is a uniformity of nature. To say that it is a *law of nature* that all material things gravitate is merely saying that all material things always do gravitate, the law being merely the assertion of the general truth. The student should carefully distinguish this meaning of the term *law* from that intended when we talk of the *laws* of a

country. In this latter case it means a *command*. A *law of science* is expressed in the *indicative mood*, *a law of a country* in the *imperative mood*. Fallacies frequently arise from a confusion of these two senses of the term *law*. The primary meaning of the term *law* is a command ; and as the laws of the land produce in certain respects a *uniformity* of action on the part of the citizens, any uniformity came to be looked upon as the result of some *law*, and finally the statement of the uniformity came to be regarded as the *law* itself.

Science is mainly concerned in the discovery of the *causes* of phenomena. When the *cause* of any phenomenon is known, the particular uniformity of nature to which it belongs is also known. Thus, if I hear a loud noise and learn that it is caused by the firing of a gun, I am satisfied with what I learn only if I know that it uniformly happens, or is a law, that the firing of a gun always produces a loud noise. When we state the uniformity to which a phenomenon belongs, or, which is the same thing, the law under which it comes, we are said to *explain* it. Thus, why does a stone fall to the earth? Because all things when unsupported do so. This answer is an explanation of the phenomenon of the fall of any particular stone. The explanation consists in the assertion that the fall of the stone is not an isolated phenomenon, but is one of a class, or merely an instance of a uniformity. Of course, we may further want an explanation of this explanation and proceed to ask—Why do all things when unsupported fall to the earth? The answer to this is the statement of a wider uniformity. Because every material thing in nature tends to fall towards everything else. We may again ask for an explanation of this and receive the answer—because every particle of matter in the universe attracts every other particle.

Each of these difficulties is in turn explained by assigning it to a wider law or uniformity of nature till we reach the widest known, beyond which we cannot go. Newton's great law is the widest uniformity yet discovered, and it seems almost as if it is never to be explained as forming merely a part of a still wider law; at least at present no answer can be given to the question — Why does every particle of matter attract every other particle? Or if an answer is given it can only be—Because the Creator has made it so, and this is nothing but a confession of our ignorance. Newton's law, then, may at present be regarded as marking out the limit of human knowledge in that direction, beyond which man's intellect cannot pierce.

It may occur to the student to ask what advantage can there possibly be in substituting a wider uniformity for a narrower one, a greater mystery for a smaller one. The answer to this is, that when we know the cause of any effect, it is often possible to imitate nature's processes, and so to produce effects that may be exceedingly beneficial to mankind. Thus, in the passage of light from one medium to another there are certain uniformities of nature exhibited. The learning of these (both effects and causes) has enabled man to produce a great number of useful optical instruments, *e.g.*, spectacles, microscopes, telescopes, and so on. In fact, as Herbert Spencer puts it, "What we call civilisation could never have arisen had it not been for science. . . . . To the progress of science we owe it that millions find support where once there was food only for thousands".*

---

* Herbert Spencer's *Education*, p. 46.

Résumé of Chapter XXIV.

I. *Cause.*

1. Definition.—The antecedent or antecedents in the absence of which the phenomenon would not have occurred.
2. Law of Causation. Every effect has a cause.
3. Law of Uniformity of Nature. The same cause always produces the same effect.
4. The Law of Causation and the Law of the Uniformity underlie all human knowledge.
5. Their truth is established by an *induction per enumerationem simplicem.*

II. *Law.*

1. A *law* of the land is an imperative.
2. A *law* of nature is the assertion of a uniformity.

III. *Explanation.*

1. An explanation is a statement of the law of nature, of which the phenomenon is an example.
2. The widest known laws are inexplicable.
3. Use of explanation.
   a. It is a satisfaction to the human mind.
   b. It is of practical value, as it often suggests valuable inventions.

Exercises on Chapter XXIV.

1. What is meant by the *cause* of a phenomenon? Give instances.
2. Night is an invariable antecedent of day, therefore it is its cause. Criticise this.

3. Explain the phrase the "Uniformity of Nature".
4. Point out two common meanings of the word *law*.
5. What is meant by the *explanation* of a phenomenon?
6. What is the Law of *Causation*? On what evidence does its truth rest?
7. What assumption is always made in predicting events?
8. "Happy is he who has been able to discover the causes of things". Comment on this.

CHAPTER XXV.

Observation, Experiment, Hypothesis.

In Chapter I. it was pointed out that all human knowledge depends ultimately on knowledge gained through the senses, that is, gained by experience. Knowledge derived solely from experience is said to be *empirical*. Empirical knowledge is the ultimate foundation of every induction. In order to make this empirical knowledge as extensive as possible, recourse is had to *observation* and *experiment*. To *observe* is to concentrate attention on phenomena as they occur in nature without any attempt to modify such phenomena in any way ; to *experiment* is to modify the time, place, or circumstances generally of nature's processes in order to be able the more conveniently and the more effectively to carry on the observation of such processes.

By *observation* we gain what knowledge we can by attending to the phenomena as presented to us in nature, by *experiment* we first make the phenomena, and then *observe* it. Thus, if we attend to the phenomena of lightning and thunder as they occur in nature we are *observing*, but if by any means we generate and then discharge such a quantity of electricity that in the discharge a small flash of lightning and clap of thunder is produced we are *experimenting*. Of course, in this case we do not really create the phenomena of the lightning flash and the thunder clap ; we bring

together those natural things from the close proximity of which these phenomena result. This is true in all cases of experiment. Again, the botanist *observes* all the natural phenomena of plant life as far as possible, but he also experiments by varying the conditions under which the plant grows.

It will be noticed that *experiment* without *observation* is worthless. *Experiment* always involves *observation*. The distinction between *observation* and *experiment* as here given should be carefully remembered, but, on the other hand, it should be noticed that no hard and fast line can be drawn between them. The man who takes the trouble to get into the most favourable position in order to observe phenomena may be said to *experiment* as well as he who varies the circumstances of such phenomena so as to render them more suited for observation. Evidently, *experiment* vastly enlarges the range of observation. Experiments with the spectroscope have revealed the elements of which the sun is composed; mere observation could never have accomplished this. By experiment the identity of the lightning flash and the electric discharge in the laboratory was established, and it is difficult to see how this could have been done by observation alone. Experiment possesses also this further vast advantage over observation: that by its means we can at will produce phenomena for the production of which by nature we might have to wait years, or even phenomena which nature might never repeat, or repeat them in such a place as to be out of the reach of human observation. For example, nature has at some past period of time produced diamonds. Possibly nature is producing them at the present time, but if so, such production is going on deep down in the earth where the process cannot be observed; by the help of experiment,

however, it is not at all improbable that nature's process may be so imitated that diamonds will be produced artificially. Indeed diamonds, though not valuable ones, have already been artificially made.

Again, consider how rapidly our knowledge of the phenomena of electricity has advanced of late years. This rapid advance is due entirely to the application of experiment. If for our knowledge of electricity we had to rely on observation alone, the times at which electrical phenomena could be studied would be limited to the occasions when thunderstorms or the phenomena of the Northern Lights occur. Progress in knowledge under such conditions cannot be other than very slow. By experiment, however, the phenomena of electricity can be produced at will in the laboratory. The importance of experiment is seen by the fact that the experimental sciences (those in which our knowledge is dependent mainly on experiment, such as chemistry and physics) have advanced more during the last hundred years than they did during the preceding two thousand years, and that it is during the last hundred years that experimental enquiry has been so vastly increased. Probably one great reason why the Greeks made so little progress in the physical sciences as they did, is that they made scarcely any use of experiment.

The following extract from Sir John Herschel's *Discourse on the Study of Natural Philosophy* puts the relation between observation and experiment in a very clear light. He says:—"Experience may be acquired in two ways: either, first, by noticing facts as they occur, without any attempt to influence the frequency of their occurrence, or to vary the circumstances under which they occur; this is *observation;* or secondly, by putting in action causes and

agents over which we have control, and purposely varying their combinations, and noticing what effects take place; this is *experiment*. To these two sources we must look as the fountains of all natural science. It is not intended, however, by thus distinguishing observation from experiment to place them in any kind of contrast. Essentially they are much alike, and differ rather in degree than in kind; so that, perhaps, the terms *passive* and *active* observation might better express their distinction; but it is, nevertheless, highly important to mark the different states of mind in enquiries carried on by their respective aids, as well as their different effects in promoting the progress of science. In the former, we sit still and listen to a tale, told us, perhaps, obscurely, piecemeal, and at long intervals of time, with our attention more or less awake. It is only by after rumination that we gather its full import; and often, when the opportunity is gone by, we have to regret that our attention was not more particularly directed to some point which at the time appeared of little moment but of which we at length appreciate the importance. In the latter, on the other hand, we cross-examine our witness, and by comparing one part of his evidence with the other, while he is yet before us, and reasoning upon it in his presence, are enabled to put pointed and searching questions, the answer to which may at once enable us to make up our minds. Accordingly it has been found, invariably, that in those departments of physics where the phenomena are beyond our control, or into which an experimental enquiry from other causes has not been carried, the progress of knowledge has been slow, uncertain and irregular; while in such as admit of experiment, and in which mankind have agreed to its adoption, it has been rapid, sure and steady."

Experiment is at a disadvantage as compared with observation in all those cases in which the phenomena dealt with are *effects*, whose *causes* are being sought. Granted a certain cause we can probably put it into action and learn what its *effect* is; but given an *effect* we cannot directly experiment to discover its *cause*. In such case we have first to guess a cause, and we can generally by experiment find out the effect of our supposed cause. If the effect so obtained be the same as the given effect the supposed cause is probably the true cause of the phenomenon. This, however, is not always the case, for different causes may, and often do, produce the same effect. Thus, let the death of a man be the given effect whose cause has to be discovered. By proving that a certain cause is capable of producing death as its effect we clearly do not prove that the death in question was due to this cause. When, in order to explain some effect, we assume a cause we are said to form a *hypothesis*. A *hypothesis* is a proposition whose truth is assumed for the purpose of deducing from it a conclusion in agreement with some observed fact. More briefly a hypothesis is an imagined cause of some known effect the real cause of which is unknown. We are all constantly making hypotheses, though we may not know that we are doing so. In fact, the human mind is so constituted that in the presence of a strange phenomenon it cannot resist the impulse to frame a hypothesis by way of explanation of such phenomenon.

Thus, on hearing of the sudden death of an acquaintance, we instantly begin to imagine causes, that is, to frame hypotheses, in order to account for it. When a hypothesis is proved to be true it is no longer to be regarded as a hypothesis, but rather as a valid induction. Newton's Law

of Gravitation was at first a mere hypothesis, but is now received as one of the most certain of inductions.

Hypotheses more frequently than not turn out to be false. It is said that Kepler, in order to explain the apparent movements of the planet Mars, made no fewer than nineteen hypotheses, all of which proved false, before he made the hypothesis that Mars moved in an elliptic orbit round the sun, which was at one focus, which hypothesis turned out to be the true one. In such cases the false hypotheses should not be looked upon as useless, for they, along with the efforts spent in testing them, often prove stepping-stones to the true hypothesis.

It should be noticed that *Imagination* is the chief faculty directly exercised in framing a hypothesis.

Résumé of Chapter XXV.

I. Experience is the foundation of all knowledge. It is gained
   1. By observation.
   2. By experiment.

II. Observation.
   1. Definition.—The attending to phenomena as they occur in nature without any attempt to modify the circumstances under which they occur.
   2. Mere observation is frequently of little use for advancing knowledge, owing to difficulties of time and of the place of the occurrence of phenomena.

III. *Experiment.*

1. Definition—Is the process of modifying the circumstances under which phenomena occur in order to facilitate the observation of them.
2. Advantages—
   a. It enlarges the range of observation.
   b. By it we can produce phenomena at will which nature produces only at rare intervals.
   c. By it we produce phenomena in situations convenient for observation.

IV. *Hypothesis.*

1. Definition.—Any supposition made to explain a phenomenon whose cause is unknown.
2. A false hypothesis often leads to the true one.

Exercises on Chapter XXV.

1. What is empirical knowledge?
2. What is the object of observation and experiment?
3. Explain the difference between observation and experiment.
4. Mention three sciences carried on mainly by *observation*, and three carried on mainly by *experiment*.
5. What advantages does experiment possess over observation?
6. Does observation possess any advantage over experiment?
7. Explain the term *hypothesis*. Give examples.
8. Show how a false hypothesis may prove useful.

CHAPTER XXVI.

Classification.

In the last chapter we saw that observation and experiment are necessary to give us empirical knowledge which we may use as a foundation for our inductions. To make inductions from this knowledge it is necessary first to arrange our facts so that those most closely connected may be closest together, that is, we must *classify* the facts given by experience. To classify is to arrange objects in groups in such a way that all the individuals in any group have certain attributes in common. We are in every-day life constantly carrying on this process. Thus we classify people into those we like and those we do not like, or into rich and poor, or into English and foreign, or into adults and those not adult, and in many other ways; books we, perhaps, classify into those that are interesting and those that are uninteresting; newspapers we arrange in classes according to the interval of time between successive issues; in fact, every time we use a general term we may be said to classify. Thus, the term *tree* suggests to the mind *trees*, as distinct from all other objects, that is, for the moment we classify all objects into *trees* and *non-trees*.

In many branches of knowledge at the present day, the number of known truths is so enormous that, without the aid of classification it would be impossible to deal with them.

It is said that botanists distinguish more than 300,000 different species of plants, and that zoologists distinguish about 2,000,000 species of animals. It is very evident that the immense amount of knowledge implied in these statements could never be learned by any individual unless he could deal with it in groups.

In forming a class a certain attribute is (or certain attributes are) chosen to constitute the connotation of the class name. All objects which possess such attribute (or attributes) are placed in the class, and all objects which do not are excluded. Hence, if we know that an object belongs to a certain class, we know also that it possesses those attributes which form the connotation of the class name.

The selection of the quality (or group of qualities) the presence or absence of which is to determine whether or not an object belongs to the class, is a most important matter. This selection settles the connotation of the name of the class. What quality is selected will depend mainly upon the purpose in view; thus, the length of life of a plant is an important matter for the gardener to consider, and for him the classification of plants into *annuals*, *biennials*, and *perennials*, is a convenient and useful one; but such a classification would be of little use to the botanist because the duration of the life of a plant has no very close connection with his purpose.

It may, in fact, be given as a fundamental principle in classifying, that the classification should be appropriate to the purpose in hand. A classification which is made to depend on the presence or absence of an attribute, or group of attributes, without reference to general similarity is said to be *artificial*. This is the kind of classification carried on

in every-day life. For example, a classification of books according to colour, or according to size, is artificial.

The scientist in classifying endeavours to arrange objects in classes according to their general similarity in such a way that members of a class may be known to have many attributes in common. A classification of this kind when properly carried out is said to be *natural*. The object aimed at then in a natural classification is the bringing nearest together those objects which are, taking all things into consideration, most alike. The Linnæan system of classifying plants was an artificial one, as the position of any plant in this system depended mainly upon the number of stamens it contained, and plants essentially unlike may contain the same number of stamens, and, further, flowers, even on the same plant, not infrequently differ in the number of their stamens. Hence, in such a system, flowers essentially alike might be far removed from one another, and flowers essentially unlike might be arranged side by side in the same class. This system has consequently been discarded, and plants are now classified upon a natural system of classification.

Flowering plants are divided first of all into two classes, *dicotyledons* and *monocotyledons*, the former containing all plants whose seeds are composed of two seed lobes or cotyledons, the latter all those the seeds of which contain but one cotyledon. The *naturalness* of this division lies in the fact that dicotyledons have many other important qualities in common besides the number of cotyledons in the seeds. Thus, in dicotyledons, the parts of the flower are arranged in multiples of *four* or *five*, the veins of the leaves are reticulate, and the stems increase in thickness by the addition of successive layers on the outside ; in

monocotyledons the parts of the flower are arranged in multiples of *three*, the veins of the leaves are more or less parallel, and the stems thicken from the inside. Hence, in the first step of this classification, plants which are essentially alike are brought together into the same class, and this is also carefully carried out throughout the classification.

It is evident that in any system of classification, natural or artificial, the classes and sub-classes could not be remembered unless they were named. The names of the classes are general terms, and connote all the attributes which determine the class. The names applied to the various classes in any classification are known as a *nomenclature*. *Dicotyledons*, *calyciflorœ*, *rosaceœ*, *prunus*, *prunus spinosa* form part of the nomenclature of botany.

In addition to a nomenclature a large number of terms is usually required in any branch of science for designating the parts of, or describing, the individual objects. These terms constitute the *terminology* of the subject. Botany again supplies an excellent example of a terminology. Whewell says:—"The formation of an exact and extensive descriptive language for botany has been executed with a degree of skill and felicity which, before it was attained, could hardly have been dreamt of as attainable. Every part of a plant has been named, and the form of every part, even the most minute, has had a large assemblage of descriptive terms appropriated to it by means of which the botanist can convey and receive knowledge of form and structure as exactly as if each minute part were presented to him vastly magnified."

The following description of *Lonicera* (Honeysuckle) taken from Hooker's *Students' Flora of the British*

Islands will give some idea of the completeness of botanical terminology:—"Erect, prostrate, or climbing shrubs, with scaly buds. *Leaves*, opposite, entire, ex-stipulate, of the young shoots sometimes lobed. *Flowers* in peduncled cymes or heads, often connate in pairs by the ovaries, and subtended by connate bracheoles *Calx-tube* ovoid or sub-globose; teeth 5, often unequal. *Corolla*, tubular, funnel or bell-shaped; tube equal or gibbous at the base; limb oblique or 2-lipped, 5-lobed. *Stamens*, 5. *Disk*, humid; *Ovary*, 2-3-celled; style filiform, stigma capitulate; ovules, many in the inner angle of each cell. *Berry*, fleshy, 2-3-celled; cells few-seeded, sepha sometimes wanting. *Seeds*, ovoid or oblong, testa crustaceous".

To one ignorant of botany much of this may seem gibberish; but to the skilled botanist such a description causes a very distinct and accurate image of Lonicera to rise in the mind.

Résumé of Chapter XXVI.

I. Classification.

1. Definition.—Arrangement of objects in groups in such a way that those in the same group have certain common attributes.
2. Necessity.—Objects are so numerous as to be unmanageable without classification.
3. Rule for classification.—It must be appropriate to the purpose in hand.

II. Kinds of Classification.

1. Artificial. — When it depends simply on the presence or absence of a particular attribute.
2. Natural.—When it depends on general similarity, the most perfect example is the classification of plants.

III. Language of Classification.

1. Nomenclature.—The names of the classes in any system of classification.
2. Terminology. — The terms used in describing individual objects.

Exercises on Chapter XXVI.

1. What is classification? Why is it important?
2. How is classification an aid to induction?
3. How is the connotation of any general term connected with classification?
4. What is the difference between an *artificial* and a *natural* classification? Give examples.
5. What is meant by a *nomenclature?*
6. What is meant by a *terminology?*
7. What is the use of a full terminology?

CHAPTER XXVII.

The Canons of Inductions.

We have already seen that inductive inferences are frequently invalid, and consequently, that such inferences must be tested before they can be received as valid inductions.

Certain rules have been drawn up, setting forth the method of procedure that must be followed in order to establish valid inductions. These rules were first enunciated by Mill in his *System of Logic*, and were called by him, *canons of induction*. These we proceed briefly to explain.

The first of these canons Mill enunciated thus:—"If two or more instances of the phenomenon under investigation have only one circumstance in common, the circumstance in which alone all the instances agree is the cause (or effect) of the given phenomenon". If we pursue knowledge in accordance with this rule we are said to follow the *method of agreement*.

The method may be clearly illustrated by means of symbols. Let capital letters denote antecedents, and the corresponding small letters consequents.

Suppose the phenomena—

A,B,C,	are	followed by	the phenomena a,b,c
A,B,D,	,,	,,	a,b,d
A,B,E,	,,	,,	a,b,e
A,C,D,	,,	,,	a,c,d
A,C,E,	,,	,,	a,c,e

in accordance with the method of agreement we may assert that A and *a* are, to a high degree of probability, connected together by some causal relation.

Jevons expresses this canon more concisely in the words —"the sole invariable antecedent of a phenomenon is probably its cause". Thus, if we find out by observation or by experiment that the formation of ice is always preceded by a certain degree of cold, and that this is, as far as we can tell, the only invariable antecedent, we may conclude that almost certainly a certain degree of cold is the cause of the formation of ice. To take a more homely example, if a person notices in three or four successive years that at the end of August he is in unusually good health, and further, that the only invariable antecedent to this state of health, as far as he knows, is a month's holiday, he may conclude that in all probability the holiday is the cause of his unusually good health.

The method of agreement does not give absolutely safe conclusions. This arises from the fact already noticed that the *same* effect may be due to different causes. It is exceedingly difficult, or, in many cases impossible, to carefully observe *all* the conditions of a phenomenon, and there is always the possibility, if the method of agreement only is employed in the investigation, that the cause is one of the unobserved circumstances. In the symbolic illustration of the method given above it may be that the fact that in all the observed cases *a* is preceded by A is a mere coincidence, and that the real cause of *a* is Z, a circumstance which has escaped notice. Hence, when a probable conclusion has been reached by the method of agreement, a further test must be applied before the conclusion can be wholly relied on. This test is supplied by

Mill's canon of his method of difference. This is:—"If an instance in which the phenomenon under investigation occurs, and an instance in which it does not occur, have every circumstance in common save one, that one occurring only in the former; the circumstance in which alone the two instances differ is the effect, or the cause, or an indispensable part of the cause of the phenomenon".

This may be illustrated thus: suppose the set of antecedents A, B, C, D, be followed by the consequents *a*, *b*, *c*, *d*: and further that B, C, D, be followed by *b*, *c*, *d*, then this canon asserts that A and *a* are causally related. It is clear *a* may be the effect of A, for it follows it in time, and that *a* cannot be the effect of B, C, or D, for *a* is absent when these are present; further, supposing A, B, C, D, are the only antecedents of *a*, then *a* must be the effect of A, B, C or D; therefore it is the effect of A.

We know a candle burns in the air, and hence among the antecedents of the burning candle is the presence of oxygen. To prove that oxygen is the cause of the burning of the candle we must remove oxygen from the air so that the presence of oxygen may not be an antecedent of the burning of the candle. This can easily be done experimentally, and then it is found that the candle no longer burns. The first part of the process, the observation of the fact that whenever a candle burns oxygen is present, leads by the method of agreement to the probable conclusion that oxygen is the cause of the candle burning; the second part of the process, the elimination of oxygen from among the antecedents and the observation that the candle then fails to burn, is an application of the method of difference and gives us the sure conclusion that the presence of oxygen and the burning of the candle are causally connected.

The method of difference is essentially a method of experiment for in experiments we generally produce phenomena in such a way that any given antecedent may be totally or partially eliminated.

Mill's third canon is :—" If two or more instances in which the phenomenon occurs have only one circumstance in common, while two or more instances in which it does not occur have nothing in common save the absence of that circumstance, the circumstance in which alone the two sets of circumstances differ is the effect, or the cause, or an indispensable part of the cause of the phenomenon ".

Suppose we observe on many different occasions that A is always followed by *a ;* and, further, suppose we notice that sets of antecedents which do not include A are invariably followed by sets of consequents from which *a* is absent, then this canon says that almost certainly A is the cause of *a*.

Thus, if we observe on many occasions that the roads become exceedingly dry, consequent upon an east or north-east wind, and that they seldom dry (the canon strictly applied would require that they should *never dry*) so quickly when the wind is in any other quarter, we may feel pretty sure that the rapid drying of the streets and the blowing of the east wind are connected by some causal relation. This is merely a method of combining the method of agreement and the method of difference, and Mill consequently called it the *joint method of agreement and difference.*

The canon of the fourth method of inquiry is :—" Subduct from any phenomenon such part as is known by previous inductions to be the effect of certain antecedents, and the residue of the phenomenon is the effect of the remaining antecedents ". This is called the *method of residues.*

To illustrate this symbolically, suppose the antecedents A, B, C are found to be followed by the consequents *a*, *b*, *c*; suppose, further, that we have already proved B to be the cause of *b*, and C of *c*, then, in accordance with this canon, A is the cause of *a*. This method is largely followed in the pursuit of those branches of science to which mathematics has been applied. Especially is this the case with astronomy. Herschel, in his *Outlines of Astronomy*, says:—

"Almost all the greatest discoveries in astronomy have resulted from the consideration of what we have elsewhere termed *residual phenomena*, of a quantitative or numerical kind, that is to say, of such portions of the numerical or quantitative results of observation as remain outstanding and unaccounted for after subducting and allowing for all that would result from the strict application of known principles. It was thus that the grand discovery of the precession of the equinoxes resulted, as a residual phenomenon, from the imperfect explanation of the return of the seasons by the return of the sun to the same apparent place among the fixed stars".

Soon after the discovery of the planet Uranus, it was noticed by astronomers that this planet presented an irregularity or perturbation in its orbit which could not be accounted for by any or all of the known forces acting on it. The cause of this residual effect was surmised to be another planet whose position was calculated from the observed amount of the perturbation of the orbit of Uranus. Observation showed this calculation to be surprisingly accurate, for on turning his telescope to the point of the sky where it was calculated the unknown planet must be, Dr. Galle, of Berlin, immediately found the planet now

known as Neptune. The discovery of Neptune is a remarkable instance of the extension of knowledge possible as a result of reasoning methodically carried out.

The canon of the fifth method, the *method of concomitant variations*, Mill enunciated thus:—"Whatever phenomenon varies in any manner, whenever another phenomenon varies in some particular manner, is either a cause or an effect of that phenomenon, or is connected with it through some fact of causation".

This method is applicable in those cases in which we cannot totally eliminate any given antecedent, but can cause such antecedent to vary in intensity. Thus, it is impossible to eliminate from a material substance *all* the heat contained therein, but the quantity of heat in such substance can be made to vary, and it is found that in every case, when the quantity of heat varies, there is an accompanying or concomitant variation in the volume of the substance. Hence this canon justifies the conclusion that increase of heat and increase of volume are connected by some causal relation.

Another application of this method of concomitant variations is what is frequently referred to as the *historical method*. This is applied mainly in ethical and political science, and has received the name *historical* because history is called upon to supply data which otherwise would be unattainable. "A certain institution, custom, or opinion is traced throughout various stages of society, and its growth or decline is connected with that of some other institution, custom, or opinion, or with the general state of civilisation prevalent throughout these periods, it being argued in the latter case that, as civilisation advances, the institution, custom, or opinion has grown or

declined as the case may be".* Many of our existing institutions have been explained by this method. Thus, the modern state has been shown to be a development and extension of the family government of patriarchal times.

The student who wishes for a fuller discussion of these canons of induction should read Mill's *Logic*, Book III., Chapters 8 and 9.

Résumé of Chapter XXVII.

The canons of the inductive methods are :—

1. The method of agreement.—If two or more instances of the phenomenon under investigation have only one circumstance in common, the circumstance in which alone all the instances agree is the cause (or effect) of the given phenomenon.
2. The method of difference.—If an instance in which the phenomenon under investigation occurs, and an instance in which it does not occur, have every circumstance in common save one, that one occurring only in the former circumstances in which alone the two instances differ, is the effect, or the cause, or an indispensable part of the cause of the phenomenon.
3. The joint method of agreement and difference.—If two or more instances in which the phenomenon occurs have only one circumstance in common, while two or more instances in which it does not occur have nothing in common save the

* Fowler's *Inductive Logic*, p. 201.

absence of that circumstance, the circumstance in which alone the two sets of instances differ is the effect or the cause, or an indispensable part of the cause of the phenomenon.

4. The method of residues.—Subduct from any phenomenon such part as is known by previous inductions to be the effect of certain antecedents, and the residue of the phenomenon is the effect of the remaining antecedents.
5. Method of concomitant variations. — Whatever phenomenon varies in any manner, whenever another phenomenon varies in some particular manner, is either a cause or an effect of that phenomenon, or is connected with it through some fact of causation.

Exercises on Chapter XXVII.

1. Explain why it is that a conclusion based on the method of agreement may be invalid.
2. Which of the inductive methods gives the most certain conclusions ?
3. Illustrate the joint method of agreement and difference.
4. Why is the method of concomitant variations indispensable in scientific inquiry ?
5. Illustrate the application of the method of concomitant variations.
6. Is *deduction* made use of in any of the inductive methods of inquiry ?

CHAPTER XXVIII.

Analogy.

Similarity or likeness is the ground of all reasoning. When we observe that many things agree in possessing certain attributes, and hence conclude that all the things of the same class possess those attributes, our conclusion is an induction; but when we compare two objects, and find that they have many attributes in common, and then, on finding that one of the objects has another attribute we infer that the other has also the same attribute, our argument is an *analogical* one. For example, knowing many points of resemblance between the Earth and Mars, and knowing further that the Earth is inhabited, we may infer from analogy that Mars also is inhabited. In this case, however, no one would place very great reliance on our conclusion.

An argument from analogy gives at best only probable conclusions. The degree of probability of any analogical inference depends on two things—

1. The relative number of known points of resemblance between the two objects to the number of known dissimilarities between them.
2. The importance of the resembling attributes in the two objects.

This second point is, however, difficult to determine and presupposes such a knowledge of the two objects as to leave

little room or need for any analogical argument from one to the other. Consequently in reasoning from analogy we have to rely mainly on the relation between the number of known similarities to the number of known dissimilarities between the two objects. In fact the fraction—

$$\frac{\text{Number of known points of resemblance between A and B}}{\text{Number of known points of disagreement between A and B}}$$

may be regarded as a more or less accurate measure of the probability of any conclusion regarding B based on an argument from analogy with A.

If we know that A resembles B in four ways and that A differs from B in four ways, we can infer nothing by analogy, but if A is known to agree with B in five points and to disagree in only three, we may infer from analogy that any additional fact m known to be true of A is more likely than not to be true of B also.

If our inference is to be purely one from analogy, the known common properties of A and B must not be known to be entirely unconnected with m, for if they are, their presence or absence can in no way affect the probability of the presence of m; nor must they be known to be connected with m by some causal relation, for in that case the argument ceases to be one from analogy and becomes inductive or deductive.

Thus, if we argue that because Mars resembles the Earth in having large patches of ice and snow round the poles, as well as in many other respects, therefore Mars resembles the Earth in having an atmosphere, our knowledge that Mars possesses an atmosphere is not due merely to analogy, for we know deductively that wherever there is snow there must be an atmosphere. Conclusions drawn from mere analogy are never to be trusted until such conclusions have

been tested by the method of induction. A man knows a mushroom is good to eat; he sees a fungus that resembles a mushroom very closely, and concludes from analogy that it is also good to eat; he eats it, and is poisoned.

The known points of resemblance between two objects are, however, sometimes so many and so great, that, knowing any fact of the one, we do not for a moment hesitate to assert the same fact of the other. Thus, suppose a new plant to be found presenting a thousand points of resemblance to the deadly nightshade, and only one known point in which it differed from it, the probability that its berries would be poisonous would be a thousand chances to one. Such a conclusion may well be compared with one reached by an *inductio per enumerationem simplicem*. The student should never rest satisfied with such inferences, but should in all cases endeavour to test them by the canons of induction. The great use of analogy is to suggest provisional conclusions to which to apply the canons of induction.

The term *analogy* has been used so far as connoting any resemblance whatever. It is, however, sometimes used in the restricted sense of a *resemblance of relations*. Thus, when a colony speaks of England as the *mother* country it is implied that the relation existing between the colony and England resembles, or is analogous to, the relation existing between a daughter and her mother. There is not much resemblance between a gardener and a teacher, or between a plant and a child; the relation, however, between the gardener and the plant is in some respects *analogous* to the relation between the teacher and child.

Résumé of Chapter XXVIII.

Analogy.

1. Definition.

   An argument from analogy is one based on any resemblance whatever.

   A resembles B in many respects, it probably does so in any other respect.

2. Difference between analogy and induction.

   a. Induction gives sure conclusions, analogy does not.

   b. Induction is reasoning that what is known of some members of a class is true of all the class ; inference by analogy is reasoning that an attribute belonging to one object also belongs to another object known to resemble it in certain respects. An analogical inference is frequently a mere preliminary to induction.

3. In reasoning from analogy the known similarities or dissimilarities must not be known to be connected or unconnected with the inferred fact.

4. Analogy is sometimes defined as a resemblance of relations.

Exercises on Chapter XXVIII.

1. Give an example of an argument from analogy, giving—

   a. A very doubtful conclusion.

   b. An almost certain conclusion.

2. What is the meaning of analogy ?

3. It is said that gold was discovered in Australia by a Californian who was struck with the apparent likeness between the rocks of Australia and the gold-bearing rocks of California. What kind of argument did he use? Answer fully.
4. Give an analogical argument to prove that the earth rotates on its axis.
5. On what does the strength of an argument from analogy depend?
6. What is a false analogy?

CHAPTER XXIX.

Relation between Induction and Deduction.

We have already (see Chapter XXIII.) seen that deduction depends on previous induction. In every syllogism the major premiss makes a general assertion. This general assertion may be the conclusion of another syllogism, and so depends for its truth on a wider statement, which again, may depend on a still wider fact; but if we trace back the foundation of the statement sufficiently far, we shall at length find that it ultimately is based on an assertion which cannot be the conclusion of a syllogism, and which must, therefore, be established by induction. Further, the premisses of an inductive argument are facts supplied by experience; hence, all our knowledge is ultimately derived from experience. Sir John Herschel says:—"We have thus pointed out to us, as the great, and indeed only ultimate, source of our knowledge of nature and its laws, *experience;* by which we mean, not the experience of one man only, or of one generation, but the accumulated experience of all mankind in all ages, registered in books or recorded by traditions".*

This explains why it is that the different branches of science tend to become more and more deductive. Fundamental

* *Discourse on the Study of Natural Philosophy*, p. 67.

principles are first established by experience, and then these are used as premisses for deductive arguments. Those sciences in which experience has already supplied all the necessary fundamental principles, and the progress of which, therefore, is due entirely to deductive reasoning, are often called the *deductive sciences*, and if their fundamental principles are established so as to admit of no doubt they are then frequently spoken of as the *exact sciences*. The best type of an exact science is some branch of mathematics, *e.g.*, the science of geometry. Mathematics, since all reasoning in it is based upon a few fundamental facts established by experience, is entirely deductive; hence the gradual application of mathematical reasoning to any branch of science marks its progress towards the *deductive* or *exact* stage.

On the other hand those branches of science, the progress of which is due mainly to the gaining of additional facts by experience (by observation and experiment), are called the *inductive sciences* or the *experimental sciences*. The physical sciences, such as heat, light, sound, electricity, chemistry, are regarded as the inductive or experimental sciences *par excellence*; but in the last few years much of the advance made in these has been due to the application to them of mathematics; in other words, even the typically inductive sciences are no longer purely inductive.

When any branch of study is pursued inductively the *method of discovery* is said to be followed. The position of the student is in such a case analogous to that of the discoverer, seeing that he is in the midst of a mass of particular facts of experience from which he has to discover the general underlying truths. To accomplish this he must collect, arrange, and analyse his facts. To analyse

is to break up complex phenomena into simpler ones. Thus the inductive inquirer following the method of discovery tries to understand the complex phenomenon of vision. His first step is *analysis*. He analyses the phenomenon into several simpler phenomena which may be separately studied. In every case of vision the following points have to be considered—

1. The luminosity of the object seen.
2. The transmission of the effect from the object to the eye.
3. The action of the eye.
4. The action of the retina.
5. The transmission of the retinal disturbance to the brain.
6. The transition from a material brain disturbance to the mental phenomenon of vision.

He then proceeds to study these phenomena separately. One may compare his position to that of a man who wants to break a bundle of rods. So long as they are together in a bundle, to break them is impossible; but let the bundle be broken up (analysed) into the individual rods and each can separately be broken. This method is frequently referred to as the *à posteriori* method, for, by following it, we reason from what comes after, or from effects, to what goes before, or to causes.

The *method of discovery* may be regarded as a synonym of the *inductive method; analysis* is one of the steps taken in following that method; and the reasoning involved is *à posteriori*. The *deductive method* is sometimes called the *method of instruction*. It proceeds from general principles to particular cases, from causes to effects, from what proceeds to what follows. Hence, the reasoning is often called

à priori. An *à priori* argument is one based on some previous general principle assumed to be true. The danger in an *à priori* argument is that our ultimate assumption may be wrong. Conclusions reached *à priori*, are to be trusted only when we know that the assumptions involved are established inductions. Conclusions reached *à priori* should always be brought to the test of experience; when such conclusions are found to tally with the facts of experience, we may feel quite confident of their truth. Thus, taking for granted what psychology has to teach concerning the constitution and development of the human mind, we may, by an *à priori* argument, reach the conclusion that in teaching children the right method is to begin with the concrete and proceed thence to the abstract.

This *à priori* conclusion is found to agree with the conclusion reached by practical teachers from their own experience, or *à posteriori*. We may, therefore, regard the conclusion as a perfectly safe one. As the scientific inquirer in induction makes use of *analysis*, so in deduction he makes use of *synthesis*. By logical *synthesis* is meant the building up of complex structures of knowledge out of simple general principles. The best possible example of this is the Geometry of Euclid. Euclid starts with a few definitions and axioms, and proceeds to build up on these, as foundation, the whole structure of his Geometry.

Résumé of Chapter XXIX.

I. Relation between induction and deduction. The ultimate premisses of all deductive arguments depend for their truth upon induction.

II. Induction.

1. The method of inquiry, by means of induction, is called the *method of discovery*.
2. The inductive method proceeds *analytically*, that is, it breaks up complex phenomena into simpler phenomena for individual consideration.
3. The inductive method is an *à posteriori* one, that is, it proceeds from what is after to what goes before, from effect to cause.

III. Deduction.

1. The method of inquiry by means of deduction is called the *method of instruction*. It proceeds from cause to effect, from rule to example, or from general principle to illustration.
2. The deductive method proceeds *synthetically*, that is, it builds up simple facts into complex structures of knowledge.
3. The deductive method proceeds *à priori*, that is, from what goes before to what follows.

Exercises on Chapter XXIX.

1. Which is more important, induction or deduction? Why?
2. Explain what is meant by an *à priori* argument.
3. Explain what is meant by an *à posteriori* argument.
4. What is *analysis?* Give examples.
5. What is *synthesis?* Give examples.
6. What is meant by an *exact science?*

CUSACK'S JOURNAL. Monthly 1d.

SCHOOL STATIONERY OF ALL KINDS.

Published by

CITY OF LONDON BOOK DEPOT,
WHITE STREET, MOORFIELDS,
LONDON, E.C.

Cusack's Series of Text Books, &c.,

FOR THE ELEMENTARY DRAWING CERTIFICATE.

CUSACK'S FREEHAND.

PART I. CONVENTIONAL FORMS.—Including Supplement containing 30 Photographic Representations of Casts. *3/6 net, post free 3/11.*

PART II. NATURAL FORMS.—Plants, Animals, and **Common Objects.** *3/6 net, post free 3/10.*

Cusack's Photographic Representations of Ornament, 30 plates, with analysis of each and instructions, being Supplement to Part I., but can be had separately. *1/6 net, post free 1/8½.*

These books form a complete course of instruction in Freehand Ornament, for all who are studying this subject for the Drawing Certificate or for Queen's Scholarship Examination. Part I. contains several hundred Exercises carefully graduated from the simplest curves up to the Examination Standard, with ample instruction in letterpress and explanatory diagrams. Part II. contains several examples of Leaves, Plants, Birds, and Quadrupeds, as well as Common Objects.

Opinions of Experienced Practical Teachers on Part 1.

"I consider Cusack's Freehand Ornament a very useful book, and remarkably cheap." J. T. Cook, *Art Master*, Sheffield School of Art.

"I can honestly recommend Cusack's Freehand Ornament as a book that all Art Teachers should have." H. Burrows, *Art Master*, Huddersfield School of Art.

"It is the most complete book on Freehand Drawing I have seen." W. H. Knight, *Art Master*, Northampton Technical School.

"It is a most valuable work, certainly the best of its kind that has yet come under my notice." John Fisher, *Art Master*, Kensington School of Science and Art, Bristol.

"The designs are good and the methods of construction eminently suited for such pupils as are preparing for the Elementary Freehand Examination, and who are unable to obtain oral lessons. It should command a good sale as the price is very reasonable for so exhaustive a work." "Art Master."

"It is a thorough reliable work, and I should be pleased to see it in the hands of all my pupils." Henry Stott, *Art Master*, Bolton Municipal School of Art.

"It seems to me to be an excellent work, and treats the subject in a thorough and comprehensive manner. It should be of great assistance to students taking either the Elementary or Advanced stages of Freehand." Francis Reily, *Art Master*, Southport Victoria Science and Art School.

"The book is full of very useful specimens suitable to the Elementary Student, and it is evidently the work of a practical teacher." Benjamin C. Hastwell, *Art Master*, Charterhouse Art School, Goswell Road, E.C.

"The work is in book form, and is very suitable for those who wish to study Freehand privately, or to place in the hands of Pupil Teachers, &c. The examples are well chosen, and the method adopted to illustrate the construction cannot fail to produce better results. The directions at the beginning of the book are also very valuable, and I trust that the work will have a wide circulation." W. H. Hey, *Art Master*, Burnley School of Art, Lancashire.

"I consider Cusack's Freehand Ornament, by C. Armstrong, will be of great service to Teachers and Students." Haywood Rider, *Art Master*, Leeds School of Art.

"I have much pleasure in testifying to the great value of Cusack's Ornament. It certainly supplies a distinct want, and I am sure that if it is really studied and taken as a guide, much good will follow." R. B. Dawson, *Art Master*, Rochdale School of Art.

CUSACK'S MODEL DRAWING.

Second Edition. 3/6 net, post free 3/10.

This book contains 200 explanatory diagrams and deals fully with many points never before attempted in a book on this subject, and but rarely even in classes. The letterpress is in each instance on the page opposite the diagrams to which it refers.

"A book for students, and one of the most complete and perfect guides to excellence in this branch of drawing that has come under our notice. The subject is dealt with in a most exhaustive manner, and every conceivable position in which the usual models can be placed is shown. We cordially recommend the work."—SCHOOLMISTRESS.

"Worthy of all praise.—Far ahead of anything we have yet seen."—SCHOOLMASTER.

"The result of several years' practical experience.—Well adapted to its purpose."—TEACHERS' AID.

"This is a splendid book, not only because it teaches model drawing on right lines, but because it teaches that *observation* and not mechanical rules must guide the student, and because it teaches what to observe and what to avoid.—We have never seen a more complete book than this one, whether for the elementary teacher or the student going in for his certificates."—ARNOLD'S ART CIRCULAR.

CUSACK'S SHADING.

3/6 net, post free 3/10

This Book contains 3 plates, full examination size, 20 finished plates, and 60 explanatory diagrams. The descriptive letterpress is in each case on the page opposite the plate to which it refers, and on the same page as the explanatory diagrams. Methods of DRAWING THE CASTS, &c., to be shaded receive particular attention.

"This is a good practical work on a difficult subject, and calculated to help students."—SCIENCE AND ART.

"A very helpful text-book.—Two interesting plates show the different methods of obtaining the 'tones' in stump and in crayon respectively.—Progressive plates are given showing each new difficulty mastered before proceeding to something fresh. This work will be found especially valuable to all who are unable to attend art classes for direct instruction."—SCHOOLMASTER.

"This is a splendid book. We do not wonder to find that it is selling well. We can honestly recommend it. When seen it will recommend itself."—TEACHERS' AID.

"The best text-book on shading that has yet appeared."—ARNOLD'S ART CIRCULAR.

CUSACK'S HOW TO DRAW THE GEOMETRIC MODELS AND VASES.

9d. net, post free 10d. New Edition.

By A. A. BRADBURY, Art Master; Examiner in Art to the Science and Art Department.

"This is a practical little book on Model Drawing, alike instructive to the student and the teacher."—*Schoolmaster.*

"A few pence will put our readers in possession of one of the most valuable little aids it has ever been our lot to see."—*Schoolmistress.*

"Excellent little book."—*Science and Art.*

"Should be in the hands ot every teacher."—*Board Teacher.*

"A most useful practical body of instruction."—*School Board Chronicle.*

"I think the idea of giving to each student a manual of instruction that contains the methods of construction he must practise to arrive at an accurate drawing, an excellent one. I hope the book may do all you have a right to expect from it." J. C. L. SPARKES,

Principal of the National Art Training School, South Kensington.

"Your work will, I trust, do much to correct the misapprehensions which are so prevalent in reference to Model Drawing."

J. A. D. CAMPBELL, Science and Art Department.

"I think highly of your little book. For shrewdness, brevity, and helpfulness, it is a model on its subject." M. SULLIVAN,

President of the Society of Art Masters.

"I have found your book exceedingly useful and a great help, especially to backward students."—J. VAUGHAN, *Art Master,* London Sch. Board.

"It is a model of conciseness and correct method of teaching. Send me one hundred copies."—J. T. COOK, *Head Master,* Sch. of Art, Sheffield.

"Your little book is full of valuable hints, and bids fair to become a very popular manual with all candidates for elementary or advanced model drawing. I wish it every success." HENRY R. BABB,

Head Master, Plymouth School of Art.

"I think the book is just what I require for my class."

CATHERINE F. MANNING, Diocesan Training Coll., Salisbury.

CUSACK'S SOLID GEOMETRY.

For SCIENCE SUBJECT I. and for ART GEOMETRY.

3/6 net, post free 3/10.

Being a complete exposition of this difficult subject as now required for the Elementary Drawing Certificate.

By HENRY F. ARMSTRONG, late Art Master, National Art Training School, late Lecturer in Solid Geometry and Perspective at the City of London School of Art, Day Training College, Moorfields, London. Now Professor of Art at the M'Gill University, Montreal.

Opinions of Experienced Practical Teachers.

"The student who now stumbles over that difficult portion, points, lines, and planes, must indeed be a dullard. Mr. Armstrong seems to have excelled in this stage particularly, and it is just here that that very useful box of models and planes called the 'Geometrikon,' issued in connection with this work, will be found very useful indeed. In this it was a brilliant idea to use transparent xylonite for auxiliary planes.

The plates and text are carefully and simply prepared, avoiding all complication, everything being easily understood."

ARTHUR SCHOFIELD, Leeds School of Art.

"I cannot speak too highly of the 'Geometrikon'; it is, I consider, the best thing of its kind I have seen."

J. T. COOK, School of Art, Sheffield.

"The book will be found of essential value to Architectural and Engineering Students. I consider it the best text book I have seen on the subject. The diagrams and Cards (The Geometrikon), showing the different planes in Solid Geometry, will be most helpful to students preparing for the Examination of the Science and Art Department."

H. BURROWS, *Art Master*, 47, West Parade, Huddersfield.

"I have carefully looked through Cusack's Solid Geometry and have decided to use it as a text book in this School. The 'Geometrikon' is a most useful addition to the book."

J. FISHER, *Art Master*, Science and Art School, Bristol.

"I am especially pleased with the 'Geometrikon,' which should greatly lessen, if not entirely remove, many of the difficulties which orthographic projection presents to beginners.

"'Cusack's Solid Geometry' and the 'Geometrikon' certainly form together a most thorough and interesting course of instruction."

G. BEDFORD, *Art Master*, School of Science and Art, Torquay.

"A student who consistently works through your book with the aid of this instrument cannot fail at the May examinations."

B. C. HASTWELL, *Art Master*, Charterhouse School of Art.

"I think your Solid Geometry and the Geometrikon are two *most useful* things, the latter especially supplying a long felt want."

JOS. HARRISON, *Head Master*, Municipal School of Art and Design, Waverley Street, Nottingham.

A STUDENT writes:—"I purchased Cusack's Solid Geometry in March; I studied it right through, giving all my Easter holidays to it. I was the only student at my centre who passed in Geometry."

Two STUDENTS write:—"We are the only two in this town who passed in Geometry; all the rest failed. We were the only two who used Cusack's Solid Geometry, and were it not for that most valuable book we should have failed also."

CUSACK'S PATENT GEOMETRIKON.

A BOX OF APPARATUS FOR SIMPLIFYING THE STUDY OF SOLID GEOMETRY.

3/6 net, post free 3/10.

The box contains:—2 mahogany planes connected by patent brass hinges, with spring, which keeps the planes at right angles to one another, so as to represent the vertical and horizontal planes of projection, but which also permits the vertical plane to fall backwards flat, so that both planes represent one flat sheet of paper, and the line between them represents the X Y line.

1 large transparent xylonite plane.

1 large opaque cardboard plane.

14 diagrams from Solid Geometry Book, on paper suitable size to fit into the hinged planes for experimental purposes.

22 auxiliary diagrams, either on transparent xylonite planes or cardboard opaque planes, as required.

1 cardboard specially cut to fold into model of tetrahedron with adjustment showing height of tetrahedron and method of finding it.

1 each small wooden cube, square prism and hexagonal prism.

2 steel pins, bead-headed.

The whole is designed to illustrate all the essential principles of Science Subject 1, from the most elementary to the most abstruse.

CUSACK'S PLANE GEOMETRY.

Price 3/6 net, post free 3/10.

This book has been specially prepared for Students who wish to acquire a thorough knowledge of Plane Geometry; contains over 300 problems fully worked out with nearly 200 additional exercises.

The descriptive matter is, in each case, opposite the page of explanatory diagrams.

To Students who have not the advantage of Oral Lessons this book will be found indispensable. No one studying it through carefully could possibly fail at a South Kensington Examination in Plane Geometry.

It is uniform in size with Cusack's Freehand, Model Drawing, and Solid Geometry.

BOOKS PUBLISHED BY PROFESSOR CUSACK.

NEEDLEWORK FOR STUDENT TEACHERS

By AMY K. SMITH, Diplomée of the London Institute for the Advancement of Plain Needlework. Special Needlework Demonstrator at the Day Training College, Moorfields, E.C. With an introduction by the Lady WOLVERTON. 3/6 net, post free 3/10. 5th Edition.

NEEDLEWORK DIAGRAMS.

By Miss A. K. SMITH.

Specially prepared for Scholarship and Certificate Candidates, and for P. T.'s.

Scholarship, 1/- net. First Year Women, 1/- net.
Second Year Women, 1/- net.

Candidate P. T's., 9d. net. First Year P. T's., 5d. net.
Second Year P. T's., 6d. net.

We strongly advise all Students troubled about the "Needlework requirements," to invest 1/ in the purchase of a set of papers on the subject by Miss A. K. SMITH. These papers are excellent in every way.

TEACHERS' AID.

CUSACK'S KINDERGARTEN DRAWING COPY BOOKS.

Complete Series in 8 Nos., 2d. net.

A preparation for Frœbel's Drawing.

Designed and arranged by C. PATTISON, A.F.S.

Specimen pages post free on application.

CUSACK'S KINDERGARTEN DRAWING EXERCISE BOOK, 4½d. net.

Interleaved with tissue. Specially prepared for drawing Kindergarten Diagrams, and for Students' use.

CUSACK'S REPRINTS OF SCHOLARSHIP QUESTIONS.

Including Answers to Arithmetic Questions.

BOOKS PUBLISHED BY PROFESSOR CUSACK.

CUSACK'S

TONIC SOL-FA MUSIC QUESTIONS.

And How to Answer Them. **1/- net.**

CUSACK'S LECTURES ON MUSIC.

Staff Notation.

3rd Edition. **2/- net, post free 2/3.**

This book comprises all the requirements in Staff Notation for Pupil Teachers of all years, Scholarship Candidates and Certificate Students of both First and Second year.

It deals very fully with Clefs, Minor Scales, Intervals, Modulation, Transposition from one Scale to another, and from one time to another, and with the Metronome in a manner never before attempted in any text book on the subject.

"The work is to be commended for its rugged outspoken style, and its terseness."—SCHOOLMASTER.

"The Lectures are thoroughly practical—Ought to prove useful to our readers."—TEACHERS' AID.

"We have gone through the book carefully, and can give it high praise."—SCHOLASTIC GLOBE.

"An excellent and highly recommendable little work. For cogency of style and clearness of expression the book is admirable, evidencing unmistakably the wide experience of the author in imparting instruction. The book is calculated to prove of much service to the Student, from the clearness and force of its style, and the thoroughness and earnestness with which the various subjects are put before the tyro."—KEYBOARD.

CUSACK'S ALGEBRA.

PART I. (ELEMENTARY), 2/6 net, post free 2/9.

Written expressly for

Scholarship Candidates (Girls), and for Second Year Women Certificate Students.

Adopted by the Chief Pupil Teachers' Centres, Training Colleges, &c.

OPINIONS OF EXPERIENCED PRACTICAL TEACHERS.

"The feature of the book is the remarkable fulness of the explanatory matter, making a demonstration on the Blackboard by a teacher quite unnecessary—a good thing for rural teachers who cannot attend a class in Mathematics."

G. M. HANDLEY, Head Master, Oldham P. T. Central Classes.

"Cusack's Algebra is an Excellent Book. Considering the class of Students for whom it is intended, it is without a rival."

JOHN FARISH ROBY, P. T. Centre, Manchester.

"This is an excellent text book, admirably suited for its special purpose, and evidently written by a practical teacher of wide experience."

G. J. RANKILOR, Director, Church P. T. Central Classes, Birmingham.

"It is a good book and very carefully graduated."

W. DONE, Supt. P. T. School, Brighton and Preston, Sussex.

"A great help to private students."

Mr. CANHAM, Mathematical Master, P. T. Centre, Norwich

OPINIONS OF STUDENTS.

"I am a student in a Scholarship Class, I procured your Algebra at the beginning, and I must say that I think it excellent. I have never attempted that subject before, and I was looking forward to its commencement with a dread of all the hard work it would entail. But I am pleased to say that I have taken a great interest in it, and enjoy its perusal exceedingly."

LOUIE ARTHUR, St. Peter's Park.

CUSACK'S ALGEBRA.

Part II. Advanced.

For Scholarship Candidates (Boys) and Certificate Students (Men), both First and Second Year. 3/6 net, post free 3/10.

Specially prepared for those Students who have not the opportunity of attending Oral Classes. Dealing very fully with Evolution, Theory of Indices, Surds, Quadratic Equations, Equations Involving Surds, Factors, Ratio, Proportion, Variation, Progression, Logarithms, Binomial Theorem, Interest, and Annuities.

CUSACK'S MENSURATION.

For Pupil Teachers, Scholarship Candidates (Boys) and Certificate Students (Men), both First and Second Year. By H. J. SMITH, B.Sc., Lecturer in Mathematics at the Day Training College, Moorfields, London, E.C.—2s. 6d. net, post free 2/9.

"We have long wanted a new book on this subject; the examples in the old ones are worn out. I endorse the remarks of Mr. H. J. Smith in his preface."
W. DONE, Supt. P. T.'s School, Brighton.

"This book is undoubtedly one of the best published. The explanations are simple and clear, and the numerous worked examples exhibit a style well worthy of imitation. The proofs of rules are especially good, and exactly meet the requirements of Certificate and Scholarship students."
G. J. RANKILOR, Director Church P. T. Central Classes, Birmingham.

"1. Many good examples worked out.
2. Exercises good and plentiful.
3. Short cuts plainly indicated.
4. Proofs simply explained.
5. Diagrams very clear.
6. Difficulties anticipated."

H. W. DUFFIN, P. T.'s School, Norwich.

CUSACK'S ARITHMETIC.

For Pupil Teachers, Scholarship Candidates, and Certificate Students, Men and Women. 4s. 6d. net, post free 4s. 10d. Second Edition.

"If it were possible for a book to supersede personal teaching, this book would make a teacher superfluous. We have here a full, clear, concise and amply illustrated exposition of the theory, and a well-selected list of graded exercises embodying every conceivable form of problem. The usual catch questions—train and clock sums, &c., are explained with the aid of diagrams (trains, clocks, &c.), with such clearness that one cannot conceive of an ordinary private student failing to work even abstruse problems. It is the best work of Arithmetic that we have seen."
PUPIL TEACHER AND SCHOLARSHIP STUDENT.

"No pains seem to have been grudged to make the whole book thoroughly serviceable, and after a careful examination, we have nothing for it but words of commendation. Many pages read like actual demonstrative lectures, with all the mark of a strong personality in the lecturer."—PRACTICAL TEACHER.

"It is, in our opinion, one of the most complete and educative treatises on the subject yet published."—SCHOOLMISTRESS.

BOOKS PUBLISHED BY PROFESSOR CUSACK.

CUSACK'S EDITION OF

SCOTT'S MARMION. Canto VI.

SECOND EDITION. For Candidates, 1901. 2/ net, post free 2/2½.

Over 200 pages, with Illustrations of all the Heraldic, Architectural, and Military Terms used in the Poem.

CUSACK'S COPY BOOKS.

Adopted by the School Board for London.

New Series. Revised and Re-engraved.

Complete Series in 8 Nos., 1d. and 2d. each. Over 5,000 Schools and many of the Training Colleges now use them.

Set of Cusack's Copy Books for Teachers' Use, in one volume, 1/6 (cloth)

What Her Majesty's Inspectors say of them:—"We are everywhere meeting with Cusack's Copy Books now, and always with a marked improvement in the Handwriting." "The Handwriting is in style perfect: it combines every excellence." "I am very pleased to see the increased use of your excellent Copy Books in the schools that I visit."

What Head Teachers say of them:—"They are all that can be desired." "The children adopt the style most readily." "The Handwriting of my school has vastly improved since their introduction." "I feel compelled to write and tell you how excellent I find them." "Every school in this town now uses your Copy Books in every department, and the improvement is most remarkable." "I have used your Copy Books with marked success."

What the Press says of them:—"We have seen no better."—SCHOOLMASTER.

"A capital series, worthy of the attention of Teachers. The style of writing is bold, neat, and taking. No. 8 especially so."—TEACHERS' AID.

"The system is simple, most carefully graduated, and results in a style of writing so beautifully legible and yet sufficiently free, that a lad on leaving school can at once take his place at the merchant's desk with nothing in his handwriting either to learn or unlearn."—TEACHERS' MONTHLY.

"We strongly advise Teachers, who are on the look out for a thoroughly good and practical series of Copy Books, to obtain specimens of this admirable series before making their choice."—SCHOLASTIC GLOBE.

CUSACK'S WRITING BOOKS (Blank).

For Blackboard Lessons.

RULED TO MATCH CUSACK'S COPY BOOKS. 1d. each.

CUSACK'S SELECTED PENS.

In 5 grades—Nos. 1 to 5—to suit writing of every size.

No. 1.—A Superior Pen for Commercial Work, or for large hand in Schools.
No. 2.—A Superior Pen for General Correspondence or for text hand in Schools.
No. 3.—A Superior strong hard-pointed Pen, for rapid writing.
No. 4.—A Superior fine hard-pointed Pen, very suitable for ledger work.
Nos. 3 and 4 are suitable for small hand in Schools.
No. 5.—A Superior Mapping Pen.

Each Pen has been carefully tested by hand before being packed, so that they will be found of uniform quality. They are guaranteed to be of the finest quality, and of great durability, being made of the finest Damascus Steel.

Specimens free to Teachers. Packed only in One Gross Boxes.

Prices:—Nos. 1 & 2, 2/- net, per gross. Nos. 3, 4 & 5, 2/6 net per gross.

Sample Box of Assorted Pens, 6d., or 2 doz. of any one number, 6d.

BOOKS PUBLISHED BY PROFESSOR CUSACK.

CUSACK'S LEAD PENCIL COPY BOOKS

FOR INFANT SCHOOLS.

Complete Series in 4 Books. Price 8d. per dozen net.

The objections to slates and slate pencils are many:—

1. It is impossible to hold the slate pencil as the pen *should be held* in writing; hence infants contract bad habits, difficult to eradicate afterwards.
2. The noise of the pencil on the slate is unpleasant, and irritating to many.
3. As the copies are all rubbed out, there can be no permanent record of the child's work or progress.
4. The means adopted in many cases for cleaning the slate is an effective cause of the spread of infectious diseases among children.

These and many other objections are at once obviated by the use of Paper and Lead Pencil.

In the above series of Copy Books, besides the Headlines being given in a bold style, the whole page is outlined with the given copy.

The very low price quoted, **only Eightpence per dozen,** *should bring them within the reach of all Schools.*

Specimen set (free) will be sent to the Head Teacher of any Infant School.

CUSACK'S BRITISH MADE LEAD PENCILS 8/. NET PER GROSS.
EVERY PENCIL SHARPENED.

CUSACK'S SHORTHAND NOTE BOOK,

200 pp., 4½d. net.

CUSACK'S JOURNAL.

A Monthly Newspaper for Pupil Teachers, Acting Teachers, and all Teachers.

Containing much instructive and educative matter. All current topics dealt with. Published 15th of each month, price 1d.; by post, 1½d., of all newsagents and stationers.

CUSACK'S PHYSIOGRAPHY.

571 pp. 3s. 6d. net.

By S. W. DAVIES, Associate of the Royal School of Mines, Murchison Medallist and Prizeman, late Royal Exhibitioner, Senior Science Master, and Lecturer in Physiography at the Day Training College, Moorfields. Specially prepared to the Elementary Stage of the South Kensington Syllabus, and for Pupil Teachers, Scholarship Certificate Students (Men and Women).

"Cusack's Physiography is an excellent book, well up to date in scientific matter, and thoroughly suitable for P. Ts. I can strongly recommend it."
T. H. KEMP, P.T. Classes, Merthyr Tydfil.

"Cusack's Physiography is an excellent book for Pupil Teachers, and other students who intend taking up the Elementary Stage of Physiography. It has the great merit of being extremely clear, and is easy to understand."
A. H. EMMS, Norwich.

"I consider Cusack's Physiography to be a first-rate work."
W. FURNEAUX, P.T. Centre, Peckham, S.E.

"It seems to be written in a thoroughly simple and masterly way."
REV. J. P. FAUNTHORPE, Whitelands College, Chelsea.

"I consider Cusack's Physiography a most useful book, well arranged, and well suited to the needs of Advanced as well as Elementary Students, to whom I shall have pleasure in recommending it."
JOHN T. DICKINSON, Central Schools, Peterborough.

"Cusack's Physiography is adapted to the requirements of the present Syllabus of Elementary Physiography, and I have no hesitation whatever in recommending the book, either to outside candidates for Elementary Physiography, or to Students in Training Colleges."
F. S. BUCK, St. Hild's College, Durham.

CUSACK'S OBJECT LESSONS.

BY LOUISA WALKER,

Head Mistress of Fleet Road Board School, Hampstead, (Infants' Department).

Part I.—2/ net, post free 2/3. Part II.—2/6 net, post free 2/9.

CONTENTS OF PART I—

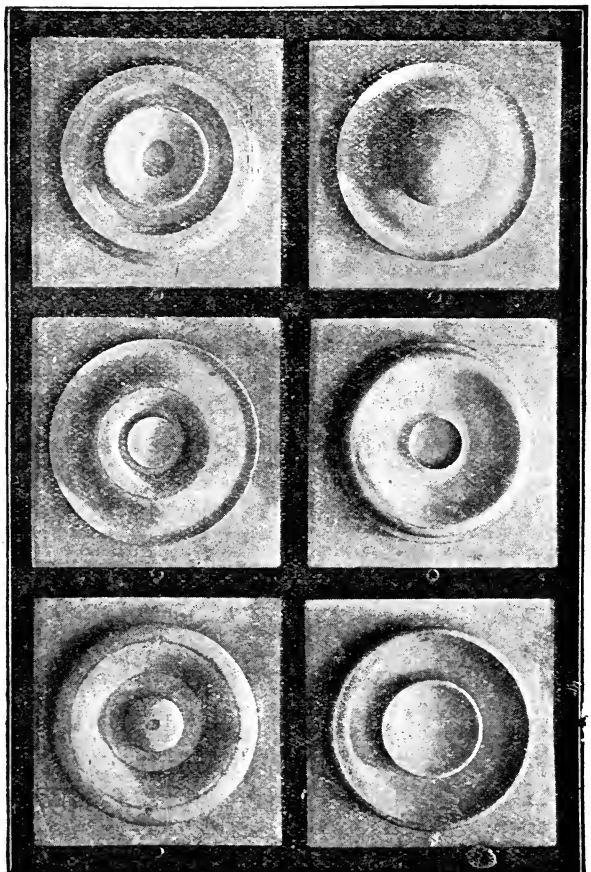
ANIMAL WORLD.

Bat — Bear — Beaver — Bees — Butterfly — Camel — Cat — Codfish — Cow — Cuckoo — Dog — Duck — Eagle — Elephant — Frog — Giraffe — Goat — Hedgehog — House Fly — Horse — Lion — Mole — Monkey — Ostrich — Pig — Polar Bear — Rabbit — Reindeer — Robin — Seal — Sheep — Silk and the Silkworms — Spider — Squirrel — Swallow and the Whale.

CONTENTS OF PART II—

MINERAL AND VEGETABLE WORLD AND COMMON OBJECTS.

Apple — Bone — Butter — Buttercup — Candles — Chalk — Coal — Cocoanut — Coffee — Coins in Use — Copper — Cork — Corn — Cotton — Cup and Saucer — Earthenware — Egg — Feather — Flax — Fruit — Fur — Glass — Gold — Gutta-percha — Honey and Wax — Horn — India-rubber — Iron — Ivory — Knife and Fork (Parts) — Knife and Fork (Manufacture) — Lead — Leather — Leaves — Milk — Needle (Parts) — Needle (Manufacture) — Orange — Paper — Penny — Potato — Pins — Salt — Silk — Silver — Slate — Soap — Sponge — Sugar — Tea — Tin — Tree (Parts) — Wood — Wool — Zinc.



From a photograph of the set of casts.

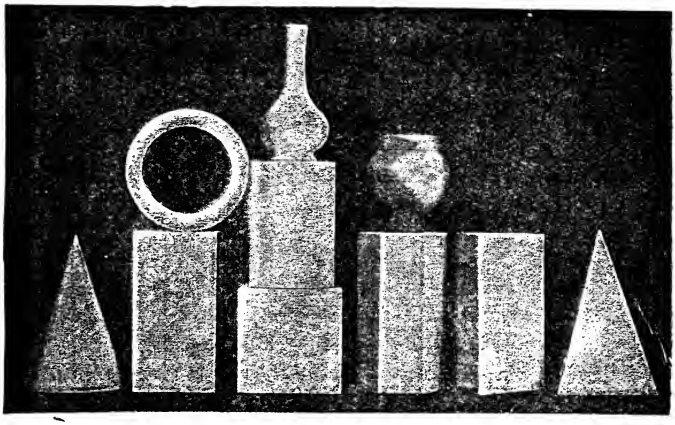
CASTS FOR SHADING.

CUSACK'S SET OF SIX ELEMENTARY ROSETTE FORMS.

(In Wood) afford the best possible practice for beginners in Shading.

On several occasions the Examination in Elementary Shading was based on a rosette.

Price 12/- net, Carriage Paid. Packing Cases and Packing Free.

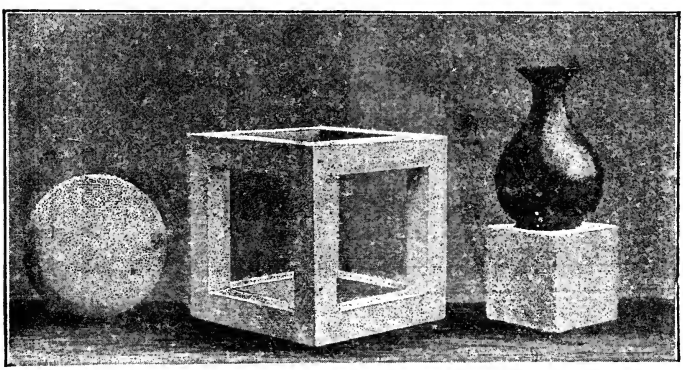


CUSACK'S SET OF 10 DRAWING MODELS.

Perfect in shape, strongly made in wood; and painted. In two sizes: Large and Small. The large is the size for Schools of Art and Art Classes. The size prescribed by the Science and Art Department for the May Exams. Large size: cube 10 in., and other models in proportion, as shown in diagram. The small size (cube 6½ in., and other models in proportion) is for students' private study.

Prices—Large Size, 40/- net; Small Size, 20/- net.

Carriage paid. Packing Case and Packing Free.



CUSACK'S SET OF 4 MODELS.

Sphere, Skeleton Cube, Small Cube, Vase. In Wood. Price 16/- net

Carriage Paid and Packing Free.

In two sizes: Large size, 16/- net; Small size, 8/- net.

Or the 14 Models complete in One Set—Large Size 56 - net, Small Size, 28/- net.

PREFACE.

THE age may be characterized as one of *unsettled* opinion. Our ambitious youth are not satisfied with the past, its opinions and practices. Authority is not worshipped by them; they have no partiality for creeds and confessions. They do not accept, without first doubting, the truths supposed to be long established. In searching into the foundation of the old temples, they have raised a cloud of dust and left lying a heap of rubbish. It is an age out of which good and evil, either or both, may come according as it is guided. We may entertain fears, for it is dancing on the edge of a precipice down which it may fall. We may cherish hope, for it is an inquiring age.

Every form and phase of opinion seeks to have a philosophy, in which it may embody and express itself and by which it may be defended. Agnostics is the shape or figure which the doubting and hesitating spirit takes. It is not a new heresy. It has been held by a few in every age; it is now espoused by many, provisionally, till something more solid or showy is propounded. It used to be called Nescience, which maintains that nothing can be known, and Nihilism, which holds that there is nothing to be known. It is of little use trying to argue with it, for it

694141

allows us no premises as a ground on which to start, and has no body or substance that we can attack. It is easy to show that it is suicidal. It is an evident contradiction to affirm that we can know nothing. But when we have demonstrated this we have not destroyed it any more than we have killed a spectre by thrusting a spear into it; for its defence is, that all truth is contradictory. The best way of dealing with it is to allow it to dance as it may, like the shadows of the clouds, and, meanwhile, to found and build up truth and set it up before the mind, that it may be seen in its own light. It is well known that when we see a solid object through and beyond a spectre, the spectre melts away and disappears. So it will be with agnosticism—it will vanish when we fix our eyes upon the truth. This is what is attempted in this little treatise.

The work is expository, and, for the reasons just hinted at, is not controversial. It is meant for those who wish, for their own satisfaction, to know the foundations on which the truth which they are required to believe rests. It is also hoped that, it being a treatise on what Kant calls Applied Logic—which may be made quite as useful as Primary or Formal Logic—it may be used as a text-book.

CONCLUSION—LIMITS TO HUMAN KNOWLEDGE, ... 57

INTRODUCTION.

We have truth when our ideas are conformed to things. The aim of this work is to show that there is truth, that truth can be found, and that there are tests by which we may determine when we have found it. We do not propose to guide inquirers in any particular department of investigation; this can best be done in introductions to the books and lectures treating of the several branches of knowledge.

Kant and the German metaphysicians have shown again and again that there is no one absolute criterion to settle all truth for us; that will determine, for example, at one and the same time, whether there is a fourth dimension of space; whether the planet Jupiter is inhabited; where the soul goes at death, and what kind of crops we are to have next year. But it can be shown that there are truths which may be ascertained, and that there are criteria which prove when they are so, and these clear, sure, and capable of being definitely expressed. But the test which settles one truth for us does not necessarily settle all others, or any others. It is necessary to distinguish between different sorts of truth, and we should be satisfied when we find a test of each kind. The aim of the criteria, it should be noticed, is not to help us to discover truth, but to determine when we have found it.

The work is divided into two Parts: one in which we seek to find the Criteria of First Principles, and in the other the Criteria of Individual Facts and their Laws.

PART FIRST.

CRITERIA OF TRUTHS TO BE ASSUMED.

SECTION I.

FIRST AND FUNDAMENTAL TRUTHS.

The mind must start with something. There are things which it knows at once. I know pleasure and pain. I do more: I know myself as feeling pleasure and pain. I know that I am surrounded with material objects extended and exercising properties. I know by barely contemplating them that these two straight lines cannot contain a space. These are called first truths. There must be first truths before there can be secondary ones; original before there can be derivative ones. Can we discover and enunciate these? I believe we can.

We are not at liberty, indeed, to appeal to a first principle when we please, or because it suits our purpose. When we are left without evidence, we are not therefore allowed to allege that we need no evidence. When we are defeated in argument, we are not to be permitted to escape by falling back on what is unproved and unprovable. It is true that we cannot prove everything, for this would imply an infinite chain of proofs every link of which would hang on another, while the whole would hang on nothing—that is, be incapable of proof. We cannot prove everything by mediate evidence, but we can show that

we are justified in assuming certain things. We cannot prove that two straight lines cannot enclose a space, but we can show that we are justified in saying so. We can do so by the application of certain tests.

SELF-EVIDENCE is the primary test of that kind of truth which we are entitled to assume without mediate proof. We perceive the object to exist by simply looking at it. The truth shines in its own light, and in order to see we do not require light to shine upon it from any other quarter. We are conscious directly of self as understanding, as thinking, or as feeling, and we need no indirect evidence. Thus, too, we perceive by the eye a colored surface, and by the muscular touch a resisting object, and by the moral sense the evil of hypocrisy. The proof is seen by the contemplative mind in the things themselves. We are convinced that we need no other proof. A proffered probation from any other quarter would not add to the strength of our conviction. We do not seek any external proof, and if any were pressed upon us we would feel it to be unnecessary—nay, to be an encumbrance, and almost an insult to our understanding.

But let us properly understand the nature of this self-evidence. It has constantly been misunderstood and misrepresented. It is not a mere feeling or an emotion belonging to the sensitive part of our nature. It is not a blind instinct or a belief in what we cannot see. It is not above reason or below reason; it is an exercise of primary reason prior, in the nature of things, to any derivative exercises. It is not, as Kant represents it, of the nature of a form in the mind imposed on objects contemplated and giving them a shape and color. It is a perception, it is an intuition of the object. We inspect these two straight lines, and perceive them to be such in their nature that they cannot enclose a space. If two straight

lines go on for an inch without coming nearer each other, we are sure they will be no nearer if lengthened millions of miles as straight lines. On contemplating deceit we perceive the act to be wrong in its very nature. It is not a mere sentiment, such as we feel on the contemplation of pleasure and pain; it is a knowledge of an object. It is not the mind imposing or superinducing on the thing what is not in the thing; it is simply the mind perceiving what is in the thing. It is not merely subjective, it is also objective—to use phrases very liable to be misunderstood; or, to speak clearly, the perceiving mind (subject) perceives the thing (object). This is the most satisfactory of all evidence; and this because in it we are immediately cognizant of the thing. There is no evidence so ready to carry conviction. We cannot so much as conceive or imagine any evidence stronger.

Necessity is a secondary criterion. It has been represented by Leibnitz and many metaphysicians as the first and the essential test. This I regard as a mistake. Self-evidence comes first, and the other follows and is derived from it. We perceive an object before us and we know so much of its nature; and we cannot be made to believe that there is no such object, or that it is not what we know it to be. I demur to the idea so often pressed upon us that we are to believe a certain proposition because we are necessitated to believe in it. This sounds too much like fatality to be agreeable to the free spirit of man. It is because we are conscious of self that we cannot be made to believe that we do not exist. The account given of the principle by Herbert Spencer is a perverted and a vague one: all propositions are to be accepted as unquestionable whose negative is inconceivable. This does not give us a direct criterion, as self-evidence does, and the word inconceivable is very ambiguous. But necessity, while it is not

the primary, is a potent secondary test. The self-evidence convinces us; the necessity prevents us from holding any different conviction.

Universality is the tertiary test. By this is meant that it is believed by all men. It is the argument from catholicity, or common consent—the *sensus communis.* All men are found to assent to the particular truth when it is fairly laid before them, as, for instance, that the shortest distance between two points is a straight line. It would not be wise nor safe to make this the primary test, as some of the ancients did. For, in the complexity of thought, in the constant actual mixing up of experiential with immediate evidence, it is difficult to determine what all men believe. It is even conceivable that all men might be deceived by reason of the deceitfulness of the faculties and the illusive nature of things. But this tertiary comes in to corroborate the primary test, or rather to show that the proposition can stand the primary test which proceeds on the observation of the very thing, in which it is satisfactory to find that all men are agreed.

Combine these and we have a perfect means of determining what are first truths. The first gives us a personal assurance of which we can never be deprived; the second secures that we cannot conquer it; the third that we can appeal to all men as having the same conviction. The first makes known realities; the second restrains us from breaking off from them; the third shows that we are surrounded with a community of beings to whom we can address ourselves in the assurance of meeting with a response.

But in order to be able to apply these criteria properly we must carry along with us certain explanations and limitations.

1. It should be noticed of intuitive truths that they are,

in the first instance, *individual* or *singular*, and that we need to generalize the single perceptions in order to reach general maxims. In them we begin with contemplating a single object, say an external object, and know it to be extended and solid, or an act of benevolence and know it to be good, or an act of cruelty and proclaim it to be evil. But we can generalize the individual perceptions, and then we have general maxims or axioms, which we can apply to an infinite number of cases. We perceive that these two parallel lines will never meet; and we are sure that we should affirm the same of every other set of parallel lines, and hence we reach the general maxim that parallel lines will never meet. We perceive, on the bare contemplation of this deed of deceit, that it is base, but we would feel the same of every other deed of deceit, and hence the maxim deceit is evil. But it should be observed that in the formation of these general principles there is a discursive act, in the shape of a generalizing process, involved. It is here that there may creep in error, which is not in the intuitive but in the discursive process; for we may form a partial, a one-sided, or exaggerated generalization. Thus, on discovering a particular effect we at once judge or decide that it has a cause. But when we would make the principle universal we may fall into a mistake, and declare that "everything has a cause," which would require an infinite series of causes and make it necessary to hold that God himself has a cause. In such a case our generalization is wrong. But let the maxim take the form that "everything which begins to be has a cause," and we perceive that on a thing presenting itself to us as beginning we should proclaim it to have had a producing power. We thus see that there may be both truth and error in our metaphysical or moral maxims: truth in the primitive perception at the basis of the whole, while there may be hastiness leading to mutilation in the ex-

pression. Hence the wrangling in metaphysics. Thus, everybody acknowledges that two parallel lines can never meet, but there may be disputes as to the fit form in which to put the axiom. So, in regard to the generalized principles that every effect has a cause, that every quality implies a substance, that virtue is commendable, there may be a difficulty in expressing exactly what is meant by cause and effect, what by substance and quality, and what by virtue and moral good; and we may find that when we would make the expressions definite we fall into grievous mistakes, and this while we are certain that there is a self-evident, necessary, and universal truth if only we can seize it.

2. First truths are of various kinds, which we shall endeavor to classify. Some of them are

Primitive Cognitions. In these the object is now before us, and is perceived by us. We perceive that this body has three dimensions in space, and cannot be made to believe otherwise. We decide that this thing, material or mental, cannot be and not be at the same time; that these two things, being each equal to the same thing, are equal to one another. In these cases the object is perceived at once and immediately. But there are others in which the object is not present, and the convictions may be regarded as

Primitive Beliefs. Here there is still an object. It is not present, but still it is contemplated. We have known the object somehow, and on conceiving it beliefs become attached to it. Thus, we know time in the concrete, and in regarding it we believe that time is continuous, that time past has run into time present, and that time present will run into time to come. A number of such faiths gather round our primitive cognitions and widen them indefinitely. We see two points in space; we are sure that there is

space between, and that the shortest line between the two is a straight line. We can rise to still higher faiths. We believe of certain objects, say space and time, and God—when we come to know him—that they are infinite, that is, that they are always beyond our widest image or concept and such that nothing can be added to or taken from them. The senses cannot give us these beliefs, nor can the understanding construct them out of the materials supplied by the senses. Some of them, such as the idea of the infinite, the perfect, lift us above our immediate experience into a higher sphere. We begin in all such cases with realities perceived or apprehended; and we are sure, if we proceed ligitimately, that we end with realities. It should be remarked that in order to our having these cognitions and beliefs it is not necessary to express them or even put them in the shape of propositions. It is necessary first to have cognitions or beliefs regarding them before we form comparisons of them or affirm that they exist or possess certain properties. But out of these we can form

Primitive Judgments, in which we predicate—that is, make affirmations or denials—or discover certain properties or relations, as when we say space and time are without bounds and exist independent of the contemplative mind. In order that these judgments may be primitive they must be pronounced as to objects which have been perceived by intuition.

I ought here to add that the mind is capable of perceiving at once certain moral qualities, and we have

Moral Cognitions, Beliefs, and Judgments. On contemplating an act of self-sacrifice done for a friend or a good cause we know it at once to be good, or an act of selfishness we perceive it to be evil. When these acts are done by our neighbors we cannot notice them directly, but we are sure that they are good or evil; and these may be

regarded as beliefs. When we put them in propositions we exercise judgment, as when we declare that sin deserves punishment.

But it will be asked, do we perceive the good and evil to be a reality, to be in the very thing. It might be allowed, it is urged, that intuitively we perceive matter to be extended and that two straight lines cannot enclose a space; for the matter, and the straight lines are before us. But moral excellence and depravity have no such reality, they exist only in our conceptions. To all this I reply that we have the acts before us in the one case as in the other; we have before us every day a deed and an implied affection of benevolence or of cruelty, and in it we perceive the morally good or the morally evil. The benevolence in this act of charity has a reality quite as much as the hand that bestows the alms or the alms bestowed. The malevolence in this calumny is a reality, quite as much as the tongue that uttered it or the newspaper that published it. The reality is of a different kind, no doubt, but it is of a kind which all acknowledge when they approve of the charity and disapprove of the scandal, and perhaps impose a penalty upon the person who has been guilty of it.

It is of vast moment, to ourselves and to the community, that we and all others should acknowledge, theoretically and practically, that there are other realities besides those of sense, and these higher and more enduring. It is the worst influence of the prevailing agnosticism that while it can have little power to keep us from believing in the things that are seen, it may have a mighty influence in keeping us from believing in and realizing the things that are spiritual, and therefore unseen, but eternal. The idealist errs when he denies the reality of a material world which, though temporal, is real. But the sensualist errs far more egregiously when he denies the existence of a spiritual

world, which is real and eternal. It should be the aim of the highest philosophy to carry us up, as Plato endeavored to do, to this high and pure region which has as high an existence as the heavens, which are its special dwelling-place. We should train ourselves, and especially train the young, to retreat from time to time into the higher world, that they may there hold communion with all that is great and good and elevating.

3. The complexity of our mental states places difficulties in the way of our applying the criteria. There are opinions which have been acquired by a lengthened and constant observation, which association has wrought into our very nature, so that we feel as if they are native and necessary; and yet some of them may be mere hereditary or popular prejudices which have no warrant in reason. In particular, experiential truths or even fancies and prejudices may so mingle with our intuitions that it seems impossible to separate them and determine which is the self-evident principle in the complex notion. These circumstances, it should be admitted, do throw difficulties in the way of the application of our criteria. But these are not greater, after all, than the application of tests in any other department of knowledge, as, for example, chemical tests to determine the existence of poisons in very complex mixtures, and generally the verification of scientific discoveries of every description. But, in spite of these difficulties, the tests can be applied if only pains be taken to distinguish the things that differ and to lay aside the things that are irrelevant. It is possible, by a careful discrimination, to separate the associated from the primitive judgment, and thus seize the conviction that is native and necessary and apply the tests to it.

4. In many instances it is essential to apply the tests to alleged intuitive truths before we put trust in them. In

some cases, indeed, the spontaneous belief is so clear and assured that we may follow it without instituting any reflex examination. But in other cases the supposed necessary truth may be mixed with extraneous matter which adulterates it. Every one acknowledges that for the purposes of accurate science it is of importance to have the axioms of mathematics and mechanics so enunciated that no empirical element has entered. In morals and jurisprudence evil consequences might arise from mixing up doubtful principles with true ones, from assuming, for instance, that the promotion of happiness is the sole and essential quality of virtue. Without a sifting we might often be tempted by indolence or prejudice to assume as true what ought to be proven, or what, in fact, cannot be proven. It is of special importance to apply these tests to all those higher faiths which perform so important a part in mystic philosophy and theology. In these there is commonly a real intuition, and this, possibly, of an elevating, inspiring order as a nucleus; but around this there may gather a halo consisting merely of mist irradiated by the light in the centre. All high minds have felt the influence of these faiths, and some have been transported by them. But earthly ingredients are apt to mingle with the ethereal and heavenward aspirations, and claim all the authority which these have. The gilding gold is made to give currency to the coin. Truth and error thus come to be hopelessly intermixed, and visions of fancy come to be regarded as revelations of heaven. The sceptic detects this, and in pulling up the tares he uproots the wheat; to vary our illustration, in tearing down the creepers he pulls asunder the wall on which they grow. These results are to be avoided by a reflex examination of the whole mental exercise. The idea of Plato, the ecstacy of the Alexandrians, the perfect of Descartes,

Malebranche's vision of all things in God, the absolute of Kant, Schelling, and Hegel, the supposed inspirations of poets and the revelations to prophets who utter grand truths—all these point to and imply high realities; but they are liable to run into fancies and extravagances, into follies and deceptions, which mislead and delude those who believe in them, pervert their judgments, and render them ridiculous in the view of the world. There is gold in the mine, and all we have to do is, by crucial tests, to separate it from the dross that we may have the true metal.

SECTION II.

REASONED TRUTHS.

When we have got truth by self-evidence or by observation, we may add indefinitely to it by inference, in which we proceed from something given or allowed to something else derived from it by the mind contemplating it. If we have truth and reality in what we start with, and if we reason properly, we have also truth and reality in what we reach. Of course if what we assume be fictitious, what we arrive at may be the same. These inferences may be of three kinds, each of which has its tests.

Immediate Inferences, or what I am disposed to call *implied judgments*. Here we have a judgment given, and we derive other judgments merely from contemplating the two notions compared. All general concepts, as logicians know, have both extension and comprehension. The extension has reference to the objects in the class; the comprehension to the qualities which combine them. Now, on the bare contemplation of the extension of the concepts we can draw certain inferences, as when it is granted that

"all men have a conscience" we infer that "this man has a conscience," even though he be a liar. From the same proposition we can draw the inference in comprehension that the possession of a conscience is an attribute of man. The canon is that whatever is involved in the extension and comprehension of a notion may be legitimately inferred.[1]

MEDIATE REASONING.—Here we do not discover the relation of two notions, or, as we call them when expressed in language, terms, by directly comparing them, but we can do so by means of a third term which has a connection with both. Reasoning thus consists in comparing two notions by means of a third. The canon of reasoning in its most general form is, "Notions which agree with one and the same notion agree with one another," with a

---

[1] From the proposition "men are responsible" the following may be drawn:

In Extension.

Every man is in the Class Responsible;
This man is responsible;
Some men are responsible;
Every tribe of mankind is responsible;
It is not true that some men are not responsible, etc., etc.

In Comprehension.

Man exists;
Responsibility is a real attribute;
Responsibility is an attribute of every man;
Responsibility is an attribute of this man;
Responsibility is an attribute of every tribe of men;
Responsibility is an attribute of some men;
Irresponsibility may be denied of all men;
No man is irresponsible;
Irresponsible beings are not men;
Men of wealth are responsible with their wealth;
To punish men is to punish responsible men.

See "The Laws of Discursive Thought: being a Text-book of Formal Logic," by James McCosh, LL.D.

corresponding dictum for negative reasoning. But the word "agree" is vague, and it is necessary to state the nature of the agreement. This is done by two formulæ, which act as the criteria of reasoning.

The Dictum of Aristotle.—We have before us a crocodile, and wish to know how it brings forth its young. Our two terms are "crocodiles" and "bringing forth their young." We find that it has been ascertained by science that the crocodile is a reptile, and that reptiles bring forth their young by eggs. We are now prepared to reason: "The crocodile, being a reptile, must bring forth its young by eggs." Here we have three terms: two called the extremes, the original ones which we wish to compare, "crocodiles" and "bringing forth their young by eggs," and a middle "reptile," by which we compare them. The process when expanded takes the form of two propositions, called the premises, and the conclusion drawn from them.

All reptiles bring forth their young by eggs;
The crocodile is a reptile;
Therefore it brings forth its young by eggs.

The conclusion is reached by the bare contemplation of the premises. The premises being true, the conclusion is true.

But this reasoning proceeds on a principle which it is desirable to have expressed and announced when it becomes the test of this kind of reasoning. It is, "Whatever is true of a class is true of all the members of the class." What is true of reptiles generally is true of the reptiles called crocodiles, and of every individual crocodile. If we have not something that can be predicated—that is, affirmed or denied—of a class to constitute a premise, no conclusion can be drawn. Thus, if only some reptiles are oviparous, if only the greater number are so, we are not entitled to conclude that the crocodiles must be so. We have thus a very decisive and easily applicable test of reasoning.

In formal logic this governing principle is spread out in various forms, so as to enable us to apply the test to every case of ratiocination. First, the syllogism is found to be the universal form of mediate reasoning. Then logicians divide reasoning according to the position of the middle term, which is the nexus of the argument, and this gives four figures. I do not mean to unfold these; they are to be found in every treatise on elementary logic. All that I have to do is to show that thereby we have a criterion of ratiocination.

All this was established by Aristotle in his "Prior Analytics." A number of attempts have been made since his day to set aside his analysis or to improve upon it. None of these have met with anything more than a temporary success. But I am not convinced that the dictum of Aristotle is the regulating principle of all reasoning; it regulates only that reasoning which involves a general notion—that is, a class notion. It can be shown, I think, that there is a ratiocination which does not proceed on the principle of classes, but of identity or equivalence. Thus, we find that the stick A is equal to the stick B, and the stick B is equal to the stick C, and we conclude that the stick A is equal to the stick C. Here we have no classes or members of a class. The canon is, "Notions which are equivalent to one and the same third notion are equivalent to one another." In ratiocination of this description the subject of the propositions may be made the predicate, and the predicate the subject:

> Shakespeare wrote "Hamlet;"
> The writer of "Hamlet" is the greatest English poet;
> Shakespeare was the greatest English poet.

All reasoning, in order to be valid, must fall under one or other of these rules, which are therefore the criteria of legitimate inference. When a professed argument cannot

be brought under either of them, it is a proof that it is not reasoning. When, on endeavoring to bring it under them, we find that it is not in accordance with them, we may conclude that the inference is not valid.

Reasoning may take several forms, which are legitimate provided they are in conformity with the dictum of Aristotle or the principle of equivalents. The natural form in ordinary circumstances is the categorical, in which we lay down a general principle and bring a particular under it; as when we say, "Consumption is a fatal disease, and as this man has consumption he has a fatal disease;" or, not being sure of the fact, we say, "If this man has consumption he has a fatal disease." This reasoning is hypothetical, and is quite as valid as the categorical. Or the reasoning may take the disjunctive form: "This disease is either a severe cold or consumption. It is not a severe cold; therefore it is consumption."

The greater portion of the reasoning in mathematics is regulated not by the dictum of Aristotle relating to classes, but the dictum of equivalence or equipollence.

SECTION III.

THE JOINT DOGMATIC AND DEDUCTIVE METHOD.

Here we begin with assuming something because it is self-evident, needing no farther proof; and then proceed to infer other truths involved. The best example is found in geometry, where there are laid down at the opening definitions of such things as triangles, circles, squares, and also axioms, or self-evident truths; and from these, and as involved in them, we get farther truths by deductive reasoning. We have also examples in Formal Logic, as

when the dictum of Aristotle is assumed, that whatever is true of a class is true of the members of the class, and from this get the modes and figures of reasoning, and innumerable inferences. The truths thus drawn are called apodictic by Aristotle and demonstrative by the moderns. In all such cases we have the tests of the assumed truths in self-evidence, necessity, and universality, and of the reasoned truth in the syllogism.

This method is powerful when we have the means of using it—that is, self-evident truths. But the field in which we have these is a very contracted one. In all investigations which deal with scattered facts the method is not available. "A clever man," says Sir John Herschel ("Nat. Phil.," § 67), "shut up alone and allowed unlimited time, might reason out for himself all the truths of mathematics by proceeding from those simple notions of space and number of which he cannot divest himself without ceasing to think. But he could never tell, by any effort of reasoning, what would become of a lump of sugar if immersed in water, or what impression would be left on his eye by mixing the colors of yellow and blue."

The method has often been applied illegitimately—that is, to departments which have to deal with scattered facts. In the sixteenth century, when mathematics were making such progress, there were attempts to carry the geometrical method into all branches of science. It was used by Descartes and his extensively ramified school in philosophy and also theology. Assuming the existence of thought, of *cogito*, as a truth which cannot be doubted, he thence proves his own existence, which it would have been wiser in him to assume, and then from the idea of the infinite and the perfect in himself, he argued there must be a perfect being existing whose veracity guarantees our idea of matter. Spinoza, in his Ethics, begins with a formidable

array of definitions, axioms, and postulates, whence he draws out a system in which God is at once extension and thought, and being the All is the morally evil in the world as well as the good. Samuel Clarke, finding that man could not get rid of the idea of space and time, argued that since all things must either be substances or modes, and as space and time are not substances, they must be modes of a substance, which is God, which by other considerations he clothed with benevolence. In these connected systems doubtful definitions were carried out, often by right reasoning, to very doubtful results. In all cases in which we have to use facts, and in which we seek to rise to facts, such as the existence and character of God, there is another method, that of induction, with it, it may be, deduction, which we may and ought to employ.

PART SECOND.

CRITERIA OF INDIVIDUAL FACTS AND THEIR LAWS.

SECTION IV.

INDIVIDUAL FACTS.

An eminent man is reported as saying that there are more false facts than false theories. There is truth in this. Facts are apt to have adjuncts to them in the reports given by others, and even in our own apprehensions of them, or they are so mutilated that they take an entirely distorted form. We all know how in story-telling additions and subtractions are apt to be made even by honest narrators, so as to make it more attractive and picturesque.

The individual facts are primarily made known by the senses. In these there may be very numerous and complicated details, and any of these if left out may so far distort our apprehensions and the account we give of them. Besides, sensations, feelings, fancies, inferences, attachments, and repugnances may mingle with our pure perception of sense and cast a glow or a gloom around them. In these sections I am showing that we have to guard against these temptations, and that when we do so we can arrive at positive truth.

Observation Proper and Experiment.—These are the two ways in which we obtain facts. In the former we

view objects simply as they present themselves; in the latter we put them in new positions. The advantage of Experiment over Observation Proper (which may be so designated as Experiment, is, after all, a kind of Observation) is that it enables us to perceive the proper action of the several agencies joined in nature. We wish to know whether bodies, whatever be their weight, fall to the ground in equal times. Common observation seems to show that they do not, as we see the gold nugget and the leaf falling at very different times. But we put the gold and the leaf into the exhausted receiver of an air-pump, and find them fall the same instant. What we should do in all observation is to note precisely what has occurred, and to report it accurately without any additions, subtractions, or coloring; we must be especially on our guard against torturing the facts in order to make them give a certain kind of testimony.

The Senses.—The older Greek philosophers adopted the common opinion that the senses deceive. The sceptics took advantage of the doctrine and argued that if the senses deceive there is nothing we can trust in. The sounder philosophers met them by calling in reason, which corrected the illusions of the senses and conducted to truth. Aristotle corrected both these forms of error, and showed that the supposed deception arises not from the senses themselves, but from the use that is made of their intimations.

To save the senses it is necessary to draw certain distinctions. In particular, we should distinguish between our original and derived perceptions. The former are intuitive, without any process of inference, having the sanction of the author of our constitution, and never deceiving us. The latter imply inferences from the revelations of sense perception, and there may be errors in them.

I believe we can approximately determine what are the

original perceptions of the various senses. By several of the senses we seem to perceive merely the bodily organs as affected. This is the case with taste and with smell, in which we discern simply the palate and the nostrils with a certain sensitive expression of the palate and the nostrils. It is the same also, I believe, with hearing and with touch proper or feeling, in which we know simply an affection of the ear and the periphery of the body. I rather think that by the muscular senses and the eye we discern more; a body resisting our organism and a colored surface affecting us. In all these intuitive perceptions there is no ratiocination, and there are and can be no mistakes. But in all beyond there are inferences, and in these there may be less or more of error. A person tells us that he had mutton to dinner, whereas all he knew was that there was a certain taste in his mouth which he argued was that of mutton. He further lets us know that he felt the smell of roses in a certain garden, where he also heard a flute playing, whereas immediately he felt only an odor in his nostrils and a sound in his ear. He is sure that he was struck in the dark with a man's hand, whereas the blow was from a stick. He depones that he saw a man strike his wife, while all he saw was an action of one figure upon another, and it turns out that the woman was not the man's wife. Hence arise some of the mistakes in witness-bearing; they are not lies of the senses, but errors in the inferences we draw from them.

In all such cases we form a general rule out of certain experiences, and in hasty thinking we illegitimately apply it. We regard sound as coming to our ear in a straight line from the sounding body, but the undulations have been reflected from a wall, and we place the bell from which they have come in that wall, whereas the belfry is actually in a different direction. It is on this principle

that the ventriloquist proceeds when he makes a human voice come from a post or an animal. Having laid down the rule that when there are few observable things between us and an object, it must be near, we look on that island seen across the sea as much closer to us than it is.

Some other distinctions must be attended to. Sensations and feelings, of pleasure and pain, of beauty and ugliness, associate themselves with all our perceptions, and are apt to give a color and even a shape to the actual things. We remember more particulars about the objects that excite us, whether joyously or grievously, than those that are dull and commonplace, and we give these a large, often an undue place in our narrative, and thus distort them and give them a different meaning.

The rapid inferences from the intimations of the senses may at times serve a good purpose. They may prepare us to meet and avoid danger when cool and correct argument would not be quick enough. A fire-bell, the jolt of a carriage in which we are riding, a stumble in walking, the fog-whistle at sea, may at times raise up an unnecessary alarm, but the calm reflection which succeeds will soon dissipate this, and at other times they save us from danger.

We have abundant means of correcting the hasty judgments. We have other senses at hand to correct the apparent deceptions of one sense. We imagine the figures raised optically by magicians to be real, but we can dissipate the illusion by thrusting our hand into the spectre. We may mistake beef for mutton as we eat it, but it is easy to apply to the person who prepared the food to set us right. A diseased eye may present objects double, but the touch will correct the mistake. In all cases we can secure that what is told us by the senses is true by judiciously using the means of correction at our disposal.

Self-Consciousness.—Metaphysicians commonly main-

tain that the revelations of consciousness are always to be trusted; that they settle everything in the last resort, and are, in fact, ultimate and infallible. But there are physiologists, and of a late date even metaphysicians, who assert that the acts of consciousness are variable and often deceitful. They show us that people often misapprehend what their real feelings are, and give a wrong account of them. It is alleged that there are persons who say that they believe certain tenets while they do not, only imagining that they do. There are cases of persons with a "double consciousness," as it is called, remembering, in the one state, their experience of that state, but without any remembrance of it in the other.

But in all such cases we attribute to consciousness what it is not responsible for. In regard to the inner, as in regard to external sense, we have to draw distinctions if we would determine its precise testimony. It is acknowledged by all psychologists that, properly speaking, we are conscious of self only in its present state. In that state there are various affections: there are sensations and feelings and inferences along with the pure consciousness, and we are apt to mix them up with each other, and thereby breed confusion in our apprehensions and in the account we give of what is in our mind. When we review our consciousness we are dependent on our memory, and we may omit some aspects of our experience and add associated affections. Here, as in regard to the bodily senses, distance is apt to lend enchantment to the view. The hypochondriac magnifies his sorrows, and the gay youth his pleasures in the past. People are apt to think their youth was happier than it really was; they remember their joys and forget the little disappointments which were then felt to be so great and now appear so little.

What is so called is not really "double consciousness."

It arises from a diseased state of the brain hindering psychical action. The person is unable to recall what has been laid up in the past, and he lives in the present and lays up a new experience, which he uses in his new state, but which he may lose in a later condition of his brain. The man is not under a double consciousness, but in two states, in each of which the consciousness may be correct.

It thus appears that man may trust in what his consciousness really reveals. It makes known to us self in its present state. It should be noticed that it does not know merely a quality of self, such as thinking or feeling; it knows self as thinking or feeling. This is of the nature of a first truth or an intuition; we perceive the very thing. This self constitutes what we call personality—that is, we know ourselves as persons. On comparing the self as presently known with the past self as then known, we declare ourselves to be the same. This is personal identity, which is a self-evident, necessary, and universal truth.

Memory.—The vulgar opinion is that the memory may deceive. But it does so only as the senses deceive. The mistakes are not in the memory proper, but in the associated affections and the inferences drawn from them. We ask a man how long it is since he visited us. His recollection is dim, and he makes the time longer than it is, six years instead of five. It is not possible for him to remember his continued existence during these years, any more than it is possible for the eye to see every point in space between us and objects five or six miles off. In both cases he has to avail himself of intervening objects. The event, he remembers, took place after his marriage, seven years ago, for his wife was with him; and before his mother's death, four years ago, for he remembers we made inquiries about her health. But he does not recollect at what precise date between these two occurrences the visit

was paid. The reminiscence is dim and he concludes that the event is more distant than it really is. Our memories in regard to time all need such mile-stones, or rather time-marks, to enable us to measure the distances. Now, in all these processes there may be mistakes. It is much the same with our recollections of the other circumstances connected with events, such as the shape and color of objects, their position in relation to other things, their surroundings, their antecedents and consequents. The vision is obscure and we have to fill it up, and we do so by fancies of our own, which so far modify the scene, perhaps pervert it. We are apt to join causes and consequences with the bare occurrences. This is especially apt to be the case with conversations, with the sentences uttered by ourselves or by others. We recollect how we felt, what we meant to say, what effect was produced on us by what others said, and we confound these with what was actually uttered. Hence the misunderstandings, the perversions which are so apt to appear in the reports of conversations. In the complicated scenes through which we have to pass we remember those parts that have been most vivid—these, I suppose, have impressed themselves most deeply on our organism, and the others are feebler. The consequence is that the record has faded in some places, and we make additions in order to complete it. In this way we clothe our bare memories with dresses, which may make them look sadder or more joyful than the events really were at the time.

But it is always possible to distinguish between our original and proper recollection and our superadded and fictitious ones. Those who are conscientious will be careful not to add out of their own stores to their memories. When the reminiscence is dim they will at once confess it, especially in witness-bearing, and when the character of a fellow-man may be affected. In all scenes which we wish

to remember accurately, we will take pains to note the exact incidents at the time they occurred. There are events of which we may be, and are certain, that they have happened.

Testimony.—It is not necessary to suppose, with some of the Scottish metaphysicians, in their answers to Hume's argument against miracles, that there is an original instinct or principle of common sense leading us to trust in testimony. I believe, indeed, that there is a social affection in all of us inclining us to have an affection for, and trust in, those we meet with, especially in father and mother, brothers and sisters, and leading us to believe in what they say. But the belief in testimony is the result of experience, and is modified by experience; we trust in certain testimonies, but not in others. There is a conscience in every man which disposes him, if he does not resist it, to speak truly; even selfishness prompts him not to lose the confidence of his fellow-men by deceiving them. Hence, the great body of mankind speak the truth when they are not led to act otherwise by a desire to excuse themselves, or by malignity toward their neighbor, or some other like motive. We can reach truth by means of testimony. It was in his haste that David said "All men are liars."

The testimony of one man is often sufficient, because of his character known otherwise; and because he has no motive to deceive. We lay down rules for our guidance in judging of testimony, as that it is a good sign if the statements are direct and unartificial. In most cases we seek to have the testimony of one man confirmed by another, that in the mouth of two or three witnesses every word may be established, it being shown that there has been no collusion or conspiracy. There are commonly circumstances which corroborate or detract from the testi-

mony. Circumstantial evidence is at times sufficient to prove that a prisoner has been guilty, when there is no direct evidence of the act. In witness-bearing, books of law and judges on the bench lay down rules which may guide the jury in the verdict which they bring in.

History.—Here the evidence is mainly that of written testimony, which, however, may be confirmed by original historical documents, such as monuments, inscriptions, coins, and ancient charters. Laplace, misled by a false analogy derived from the diminution of light when reflected successively from a number of surfaces, declares that the value of testimony may be weakened by transmission, and at length altogether lost (*Essay on Prob.*). This is true of tradition, that is, of oral testimony transmitted from mouth to mouth, or from age to age; but Sir G. C. Lewis (*Meth. Obs. and Reas.*) has shown that, "when the testimony of the original witness has once been obtained and recorded, either by himself or others, in an authentic form, it is perpetuated so long as the written memorial of it is preserved in the original, or in a faithful transcript, and may at any time be used for historical purposes."

SECTION V.

INDUCTION.

This consists essentially in gathering facts in order to ascertain the order that they follow, which will be found to consist in laws which they obey. It was known to Aristotle that the mind starts with the singular (*τὸ ἑκάστον*) before it rises to the universal (*τὸ καθόλου*), which, as he expresses it, may be first in the order of nature, while the singulars are first in the order of time. He practised the method in his natural history, very specially by the collec-

tions which were supplied by his pupil, Alexander the Great. But he cannot be said to have systematically expounded induction as a method of discovering truth. This was reserved for Francis Bacon, who enjoined that in observational science, the mind should begin with particulars, which are to be collected and collated, and then rise to minor, middle, and major axioms, and thence finally to causes and forms. All this was to be done not *per saltum*, but by gradual steps. The method has since been made more definite by Sir John Herschel, in his "Natural Philosophy;" by Dr. Whewell, in his various works on "The Philosophy of the Inductive Sciences;" by John S. Mill, in his "Logic," and by others. The method will become more perfected as science advances with its observations and experiments, with its instruments and its critical examinations. That method has a Means and an End. The Means are observation with analysis. The End is the discovery of laws.

Analysis and Synthesis.—By the former we separate a concrete or complex object into its parts. In chemistry there is an actual separation of one element from another, say the oxygen from the hydrogen with which it is combined in water. But in most investigations, the separation is in thought. Thus in all bodies we find both extension and energy, which cannot be separated in fact. Thus logicians analyze discursive thought into simple apprehension, judgment, and reasoning, or in the expression of these into the term, the proposition and argument. The process is performed by abstraction, in which we contemplate in thought a part of a whole presenting itself, more particularly an attribute of an object, say gravitation. In analysis we separate the whole into its several parts. Abstraction can be performed on every object, as every object has more than one quality, and we can fix on any one of these. Analysis

can be performed only when we have such an acquaintance with an object as to know all its parts.

The exercise of abstraction, and when it is available of analysis, is required in every kind of investigation. Bacon speaks of induction, commencing with "the necessary rejections and exclusions," that is, the separating of the matter to be investigated from the extraneous objects with which it may be associated in nature. Whately says ("Logic") that in teaching a science, the analytical mode is the more interesting, easy, and natural kind of introduction, as being the form in which the first invention or discovery of any kind of system must originally have taken place. Whewell gives an apt name to the procedure, which he recommends as the "Decomposition of Facts." It serves not only to separate objects from others, but to break them down, so that we may obtain a better acquaintance with them, with their internal structure and their several qualities. It is a process to be employed throughout in all investigations of nature, which in every department is full of complexities.

Analysis can scarcely be described as discovering truth. It is rather a means or instrument toward this end. At the same time, it should be noticed that when we abstract a part, say a quality, from an object, the part, the quality, has a reality as well as the whole. If the concrete be real, the abstract is also real. The abstract may not have an independent reality; thus gravitation has no reality except in body, but it has a reality in body. The criterion here is that the part be really a part of the actual whole, that the quality be a real attribute of a real thing.

Analysis is a sharp and may become a dangerous instrument. It may be over subtle and dissect and kill what should be kept alive and entire. It is fulfilling its end only when, to use an illustration of Plato's, it is dividing the

carcass as the butcher does, according to the joints. Among the ancient Greek philosophers the analytic was the method commonly employed. Down to this last age the analytic and the synthetic were represented as methods of discovering truth, and had large fields allotted to them. Kant's great work, the "Critick of Pure Reason," is divided into the analytic and synthetic parts.

In synthesis the parts are put together to show that they make up the whole. Thus Whately decomposes discursive thought into the term proposition and argument, and then shows synthetically that these make up the whole process. Sir John Herschel, in his "Astronomy," begins with taking up the several departments of the heavens, and then expounds the whole science. The two, analysis and synthesis, must continue to be used as instruments, but they now do so in the methods of induction and deduction.

Criteria of Laws.—Hitherto we have had to do with individual facts, which tell us nothing beyond themselves. We have not as yet any means of anticipating the future from the past, or gathering wisdom from experience. In particular, we have no science, which consists, not of scattered and isolated facts, but of systematized knowledge. In the construction of science we must co-ordinate the facts. In doing so we discover the laws and find that all mundane affairs are regulated by laws.

But the question arises, How do we from individual facts reach a law? Or, more specifically for our present purpose, When are we entitled to conclude and be satisfied that we have found a law which may be regarded as general or universal? The answer of those who have not thought specially on the subject would be, When we have observed all the facts. But a moment's reflection shows that in most cases, I believe in all, we cannot find out all the facts. We assert that crows are black, but we cannot

go the round of the world and ascertain that it is so. We may have examined millions of cases and found all crows black, but how do we know that a traveller may not report that he has found a white crow in some distant island? In science we say that all mammals are warm-blooded, or that all matter attracts other matter inversely according to the square of the distance; but no one has searched the universe and noticed every mammal and every particle of matter so as to be able to say that no mammal is cold-blooded, and no particle of matter without the power of attraction. But from a limited number of observations we can rise to a law which seems to be universal. How is it so? Mr. Mill maintains that he who can answer this question is wiser than the ancients.

Bacon describes the method of observation by "perfect innumeration" of cases as puerile and incapable of yielding any fruitful results. In induction we have to rise from the unknown to the known. We argue from a limited number of cases in the past to a universal law which we hold to be true in the future, not only so, but in all unknown cases, past and present. The father of inductive philosophy was aware of the difficulty of the problem, and he sought to solve it by bringing in Prerogative Instances (*Prerogativæ Instantiarum*) which could determine what is true of all instances. To give only one example, that of *Instantia Crucis*, the metaphor being taken from the notice put up where two roads meet to tell which to take. It was disputed whether light consists of material particles or of vibrations in an ether. To settle this it was maintained by Fresnel that instances can be artificially produced which are inconsistent with the material, but not with the undulatory theory. But we have now better tests in the Canons of Induction.

In all such investigations we must take along with us

two grand principles. One of these is the principle of Cause and Effect. I believe this to be an intuitive principle, standing the tests above enunciated. I believe that when we discover anything beginning to be, we look for an antecedent producing it—a substance with power. But without entering at this place on this disputed metaphysical subject, I may take it for granted that the principle of causation is sanctioned by a universal experience, and will not be denied by any one. Many, indeed, feel that the principle may require to be enunciated anew and put in a better form since the discovery of the law of the Conservation of Energy, or the Persistence of Force, as Herbert Spencer calls it. But whatever be the best shape in which to put it, we assume in all induction that causes produce their proper effect, and that every new product or change in an old thing has a cause. One of the aims of inductive science is to discover what has caused a given phenomenon, what has produced it in the past and will produce it again. But we have need to assume more than this.

The second is the principle of the Uniformity of Nature, as it is loosely called. The principle of causation might have reigned in all nature and yet there have been no uniformity. All action in nature might have as its sole cause the fiat of God. The connection of all things would, in this case, be with God, but not with one another. The spring, with its buds and blossoms, would be produced by God, but this would give no security that the fruits of autumn were to follow. Or, again, there might be constant interferences by God with the operation of natural agents; or causal agents might work, and yet there be no such thing as the general laws, such as the seasons, which we observe and trust in. We find, instead, that the agents of nature are so disposed or arranged that they produce uniformities, not the result of any one cause, but of a com-

bination and harmony of causes, such as the periodicity of the heavenly bodies, the flow of the tides, the regular return of the seasons, the plant rising from a seed and producing a seed, the descent of the animal from a parent, its growth and its death. All these imply causation, but they require more—an adjusted causation.

But it is necessary to settle more definitely what is implied in the uniformity of nature which lies at the basis of all induction. It implies first that there is a certain number of agents acting in nature—it is not necessary for us to settle how many. Secondly, that these are so collocated or arranged—I believe, adjusted—as to produce general results called laws, which we observe and act upon and can scientifically express. Thirdly, these agents constitute nature, and there is no introduction of new agents and no interference with them in ordinary circumstances. This statement does not preclude miracles on rare occasions, these miracles not being contrary to the law of causation, for they have the power of God as a cause, but they are simply an exception to the uniformities of nature.

We thus see that there are two kinds of laws sought after in induction. The one, the primary and the fundamental, are the laws of causation. In the inquiry into these, we seek to settle the precise nature of the causes acting—what is the precise nature of the power which keeps the moon in her sphere and makes the apple fall to the ground. Or, having discovered the cause and its nature, we try to find what will be its influence and effect in certain circumstances—how, for instance, gravity will produce tides in the ocean.

Canons of Induction.—There seem to be three grand ends which men of science have in view in their investigations. One is to discover the composition of the objects around us; the second is to discover natural classes; the

third is to discover causes. There are canons which guide and guard us in each of these investigations.

I. *Canons of Decomposition.*—Almost all the objects we meet with in the world, whether material or mental, are composite. It is the aim of many departments of science, in particular of chemistry and psychology, to analyze them. This can, so far, be effectively done. There are certain rules to guide us, and these may be made more and more specific as the analytic sciences advance.

A. We must separate the object we wish to decompose from all other objects. If we wish to analyze water, we must have pure water separate from all other ingredients. If we wish to analyze intuition or reasoning, we must separate it from all associated observations and fancies.

B. When we have found the composition of any piece or portion of a substance, we have determined the composition of every other part, and, indeed, of the whole. When we have ascertained that a pint of water is formed of hydrogen and oxygen, we have settled that water everywhere is composed of the same elements. This arises from the circumstance that every substance in nature has its properties which it retains. Having detected these properties in one case, we have found what they are in all.

C. The elements reached are to be regarded as being so only provisionally. We are not sure that in any cases we have found the ultimate elements of bodies. At present it is supposed that there are sixty-four elements, but we are not sure of any one of these that it will never be resolved into simpler substances. Meanwhile the chemical analysis is correct so far as it goes. It will always hold true that water is composed of oxygen and hydrogen, though it is possible that oxygen or hydrogen, one or both, may be resolved into something simpler.

Canons of Natural Classes.—There are certain sciences

which are called by Whewell classificatory. They are such as botany, zoology, and mineralogy. We may have two ends in view in classifying; one may be simply to aid the memory by having the innumerable objects of nature put into a convenient number of groups. For this purpose we fix on certain obvious and convenient characteristics and put all the objects possessing them into one class. It was thus that Linnæus put under one head all plants possessing the same number of stamens and pistils. This arrangement, though it does not come up to the requisitions of a perfect classification, is found to be very convenient. Second, our object may be to increase our knowledge by so arranging objects that one characteristic may be a sign of others. In natural classification we should always aim at securing both these ends. There are canons which may assist us in determining when we have reached natural classes.

A. We must have observed the resemblance in many and varied cases, say in different countries and at different times.

B. We must be in a position to say that if there had been exceptions, we must have met them. These two rules guard against forming a law from a limited class of facts.

C. There are classes in nature called Kinds, in which the possession of one quality is a mark of a number of others. All classes entitled to be called natural are more or less of this description. Thus, mammals are so designated because they suckle their young; but this characteristic is a mark of a number of others—that the animals are warm-blooded, and have four compartments in their hearts. Reptiles are recognized as producing their young by eggs, but they are also marked as having three compartments in the heart, and being cold-blooded.

These canons guarantee truth. When we are able to place objects in a class, we know that they possess the properties of the class.

Canons of Causes.—The most lucid and, upon the whole, the clearest and most satisfactory exposition of these methods is by Mr. John S. Mill in his "Logic." It should be noticed that his methods relate to causes, and we have not had from him an exposition of the canons of decomposition and classes as given above. He mentions four or five methods.

A. The Method of Agreement.—In the spring season we see innumerable buds, leaves, and blossoms appearing upon the plants, and we find the common cause to be the heat of the sun shining more directly upon the earth. The canon is, "If two or more effects have only one antecedent in common, that antecedent is the cause, or, at least, part of the cause." That canon is too loose to admit of a universal application, as we may not be sure that the point of agreement we have fixed on is the only one.

B. The Method of Difference.—In the very middle of the day I find the scene around me on the earth suddenly darkened. There must be a cause. I find that the moon has come between us and the sun, and this seems the only difference between the two states—the one in which everything was bright, and the other in which it is in gloom. The canon is, "If in comparing one case in which the effect takes place and another in which it does not take place, we find the latter to have every antecedent in common with the former except one, that one circumstance is the cause of the former, or, at least, part of the cause." This method is the one employed in cases in which experiment, with its separating power, is available. It is the most decisive of all tests when the circumstances admit of its application. There are cases in which this

method is not applicable, when a sort of intermediate one may come to our aid.

C. The Indirect Method of Difference, or the Joint Method of Agreement and Difference.—The canon is, "If two or more cases in which the phenomenon occurs have only one antecedent in common, while two or more instances in which it does not occur have nothing in common but the absence of that antecedent, the circumstance in which alone the two sets of cases differ is the cause, or part of the cause, of the phenomenon." The illustration given by Mr. Mill is: "All animals which have a well-developed respiratory system, and therefore aërate the blood, perfectly agree in being warm-blooded, while those whose respiratory system is imperfect do not maintain a temperature much exceeding that of the surrounding medium; we may argue from the two-fold experience that the change which takes place in the blood by respiration is the cause of animal heat."

D. The Method of Concomitant Variations.—We want to know the cause of the rise of water in a pump or of mercury in a barometer. The ancients accounted for this by nature's horror of a vacuum, which is inconsistent with the fact that water will not rise above a certain number of feet in the pump. Torricelli and Pascal gave a better explanation when they referred the rising of the water or mercury to the weight of the incumbent atmosphere, which Pascal proved by ascending a mountain with a barometer, and finding that, as he rose higher and higher, the mercury fell lower and lower in the tube. Here we have the effect varying with its alleged cause, which is an evidence that the alleged cause is the true one. The canon is, "Whenever an effect varies according as its alleged cause varies, that alleged cause may be regarded as the true cause, or, at least, as proceeding from the true cause."

E. The Method of Residues.—A farmer knows how much grain a particular field has yielded in the past. He mixes manure with the earth on the field, and finds he has a larger crop, and he ascribes the increase to the manure. He knows what the previously existing antecedents will produce, and after subtracting this, he ascribes the residue to the new antecedent. The canon is, "Subtract from an effect whatever is known to proceed from certain antecedents, and the residue must be the effect of the remaining antecedents."

I do not need here to give anything more than the above general account of these canons, which are fully unfolded by Mr. Mill. I mention them simply to show that when they are applied they settle for us what is truth.

Reasoning in Induction.—The question is started, Is there reasoning in induction? I am sure that there is. From what has been ascertained by observation taken in a wide sense we infer something else—that there is a law which enables us to predict results.

How is it that the countryman is enabled to predict a coming storm? His father has told him, or he himself has observed that when the wind is in the East, and the clouds are thick and black, there will probably be rain or wind. Here there is evidently inference which can be stated syllogistically by the logician, the general observation being the major premise, the particular state of the wind and sky the minor, and the conclusion that there will be a storm. Every class of men, in fact all men, do thus reason on premises implied, though possibly not expressed. The laborer argues, in his own way, that there should be a rise of wages; the merchant purchases because he concludes there will be a demand for his goods. Before there were any precise rules laid down on the subject, scientific men drew true and important conclusions from common-sense principles in their own mind. The canons of in-

duction now expressed definitely enable us to put the reasoning in a more systematic form, which is a great advantage. We can now use the canons of induction (which, I believe, will become more definite and better expressed) as our majors in the syllogism of induction.

Major. When two or more effects have only one antecedent in common, that antecedent is the cause.

Minor. But the budding of innumerable plants in spring has only one common antecedent—the return of the sun to a higher altitude.

Conclusion, this one antecedent *is* the cause.

This is the method of agreement. Let us take a case from method of concomitant variations.

Major. Where an effect varies with its supposed cause, this is the true cause.

Minor. But the rising and falling of the mercury in the barometer varies with the less or greater weight of the superincumbent atmosphere.

Conclusion, the weight of the atmosphere is therefore the cause of the rise or fall of the barometer.

It should be observed that the canons, with their implied reasoning, do not guarantee to us absolute certainty, what is called apodictive truth or demonstration. None of these are certified, as first truths are, by the law of necessity; we can easily conceive any one of the ordinary physical laws not to be true universally, and we might believe so provided we have evidence. The evidence, after all, is merely a probability of a lower or higher degree, but may rise to a certainty only a little short of being absolute, and quite sufficient to justify us to put trust in it and act upon it in ordinary, indeed in all, circumstances. Such, for instance, is the proof which we have in favor of the law of gravitation. It is not demonstrative like a mathematical truth, but it satisfies the mind and is verified by constant observation.

SECTION VI.

THE JOINT INDUCTIVE AND DEDUCTIVE METHOD.

J. S. Mill argues that more progress will now be made even in observational sciences by deduction than by induction. This may be doubted. It seems to me that observation and experiment must always be the surest way of advancing research. But deduction may be joined to induction. When this is done the method may be called the Joint Inductive and Deductive. This is, in fact, the method represented by Mr. Mill as conducting to such fruitful results.

In this method the inquirer begins in the inductive method, that is, he observes facts with care and with the view of discovering a law. As he proceeds he will ever be asking whether the law is so and so, that is, devising an hypothesis. In order to determine whether this is a true law of nature, he has to examine further facts, it may be, facts of a different kind. As he acts thus, he may find he can apply deduction. He inquires what effects follow from the law in his mind, and he then compares these with the facts. If he finds these to correspond, he has a Verification of his Hypothesis. It is by combining the two in this way that the greater number of the established laws of nature have been discovered. In some cases there have been long processes, both of induction and deduction, before the law has been ascertained and adjusted. When the laws of nature are quantitative, as they commonly are, mathematics may be applied to them, and it becomes the instrument of the deduction, and often a far-reaching one, showing very distant consequences which can be compared with facts.

In the sciences of observation sometimes the inductive

element and sometimes the deductive method is the more prominent; in all cases the inductive, as I reckon, is the essential. In Galileo's researches experiment was the main instrument, but he also used mathematics. Kepler's fertile mind was always devising hypotheses, but he accepted them only as they were confirmed by observations. It would be wrong to say that Newton's method was mere induction. He had before him the observations of Galileo and Kepler, and also a measurement of the distance of the earth's surface from the centre, and he applied a powerful mathematics, created by himself, to these facts. It is a circumstance greatly to his credit that when, on having a wrong measurement of the distance of the earth's circumference from its centre, he found his theory that the moon was held in her sphere by the same power as draws an apple to the ground not in accordance with facts, he gave it up for a time, and only resumed it when it was found, on the proper distance of the earth's distance being ascertained, that the facts corresponded. In all departments of physics or natural philosophy the deductive mingles with the inductive. In optics, in thermotics, in theoretical astronomy, in mechanics, the deductive or mathematical element has a conspicuous place; but in all these sciences we have always to start with observed facts. In ethics we carry out indefinitely the laws of our moral nature; but these have been ascertained by a previous observation of that nature. In like manner, in logic we deduce consequences from the laws of discursive thought, which we have found by observing how they act in the mind. In all the social sciences there is a mixture of the two elements, sometimes the one and sometimes the other being the more predominant. Jurisprudence is forever appealing to fundamental principles, and inquiring how they apply to a given case. The science of national wealth must be

constructed mainly by the observation and collection of facts, in statistical and other forms; but there are universally operating principles ever called in. Thus it is supposed that men are usually swayed by a desire to promote their interest so far as they know it. This is certainly a powerful motive. But there are others, such as the desire for fame, for power, for society, for the beautiful, for the promoting education and religion, all actuating individuals, and the influence may be traced in the progress of nations. In chemistry the laws have to be ascertained by observation, particularly by experiment; but when principles have been discovered, such as that of affinity, they may be carried out indefinitely. Psychology, as a science, is constructed mainly by the observations of consciousness; but having ascertained certain laws, such as those of the association of ideas, we can explain how they affect our beliefs and feelings. In pedagogics, or the science of teaching, we must carefully observe the ways of children; but, in doing so, we discover their actuating motives, such as the love of knowledge, the love of play, the love of approbation, which have to be taken into account in constructing our methods of instruction and discipline. In æsthetics there are ascertained laws of taste which must be taken along with us in the construction of the science. In all departments of natural history, observation must play the most important part; but there are laws of life and of form to guide biologists in all their investigations.

The principles from which we deduce conclusions are of two kinds. Some are self-evident or demonstrative. Such are moral laws and maxims. These are assumed, and are applied extensively and constantly in history and in all the social sciences, in all sciences which deal with motives and character. Of this description is the maxim that men are likely to be happy and comfortable when

they are moral. To this same class belong all mathematical propositions founded on axioms. These self-evident truths are seldom formally enunciated, they are simply assumed and applied. So far as science uses them, it is very much employing the joint Dogmatic and Deductive method. But there is a second kind of principles used in deduction even more extensively; these are acknowledged truths and wise saws established by a large induction. For example, any one may now assume the law of gravitation. In optics it is allowed that the angle of reflection is equal to the angle of incidents, and from this a great many particular truths may be drawn. In chemistry it is taken for granted that the elements combine in certain proportions, and from this a multitude of consequences follow.

In this joint method the induction is tested by the canons of induction and the deduction by the rules of reasoning.

Hypotheses and Verification. Consilience of Inductions.—"Hypotheses non fingo," said Newton, meaning, perhaps, that he introduced no fictitious agency, but merely *veræ causæ*, such as existed in nature; or, more probably, that he accepted no truth till it was established. Since Newton's time, especially within the last age, hypotheses have played a very important part in all departments in which the laws have not been settled, as, for example, in electricity and biology. The investigator is bent on knowing what laws certain phenomena follow. But in nature divers agents are mixed up with one another, and we cannot determine what they are by a loose inspection. As he observes tentatively, he makes a supposition suggested by the facts as to what the law should be. When he notices the descent of plants and animals, he says to himself, Let us suppose the law to be that of development or heredity. He has now a specific end to work for, and he observes

and collects facts, and inquires whether they agree with the hypothesis he has formed. If he finds that many of them do so, he has a probability, and is encouraged to proceed; and if the hypothesis explains a large body of events it rises to the rank of a theory. When it takes in all the facts bearing on the particular case, and no exceptions can be discovered, it is regarded as a law of nature, which, however, may require to be modified and adjusted before it suits all the facts, and so becomes the true law. This process is called

The Verification of Hypotheses.—When first suggested the supposition may have little to support it, and there may seem to be facts opposed to it. But if it is the correct one, there will come confirmations from a variety of quarters, difficulties will disappear, and the seeming exceptions may corroborate it. The hypothesis started is that light consists in vibrations, not a very probable supposition beforehand, but then it is found to explain one set of phenomena after another, till at last it seems to account for everything, and is counted as an established law. Or the hypothesis is that of the conservation of energy, or that the amount of energy in the world, real and potential, cannot be increased or diminished. On the first consideration of this view, obvious objections will present themselves. We strike with a hammer upon a piece of iron till our strength is exhausted, and it looks as if force had been expended and lost. But, on further inquiry, we detect the energy that had gone out of the body to be conserved in the molecular motion or heat of the metal.

Hypotheses, I rather think, must be resorted to in the early stages of the investigation of every sort of phenomena. They are simply tentatives, and most of them may have to be abandoned. They may or they may not be announced: they may, in the first instance, be simply

guesses, and only a few or one of them prosecuted to any great extent. The law of gravitation was for a time only an hypothesis, taking the erroneous form that matter attracts other matter, not according to the square of the distance, which is the true law, but according to the distance. Hypotheses are necessary, but are to be carefully watched and limited.

First.—The hypothesis must be suggested by the facts and not be feigned by the mind; this may be the meaning of Newton.

Second.—It must be regarded as a mere hypothesis till it is established by the criteria applicable to the department. We are much troubled in the present day by hypotheses being represented as established laws.

Third.—The hypothesis is to be abandoned when it is found that there are facts inconsistent with it. It requires much courage to abandon an hypothesis which has long been cherished and perhaps published to the world.

Fourth.—It is established as a law when it explains all the phenomena bearing on the subject and is not contradicted by any known fact.

It is a powerful confirmation of an hypothesis when it enables us to predict occurrences. If the alleged law be the true one, the facts will correspond to it in the future as in the past, and as they fall out will tend to prove that the hypothesis is a sound one. Dr. Whewell has shown that the evidence in favor of our induction is of a much higher and more forcible character when it enables us to explain and determine cases of a kind different from those which were contemplated in the formation of our hypothesis. "Thus it was found by Newton that the doctrine of the attraction of the sun, varying according to the inverse square of the distance, which explained Kepler's third law of the proportionality of the cubes of the distances to the

squares of the periodic times of the planets, explained, also, his first and second laws of the elliptical motion of each planet, although no connection of these laws had been visible before. Again, it appeared that the force of universal gravitation, which had been inferred from the perturbations of the moon and planets, by the sun, and by each other, also accounted for the fact, apparently altogether dissimilar and remote, of the precession of the equinoxes." He designates this process as the Consilience of Inductions. He declares: "No example can be pointed out in the whole history of science, so far as I am aware, in which this consilience of inductions has given testimony in favor of an hypothesis afterward discovered to be false."

SECTION VII.

CHANCE.

In one sense there is and can be no such thing as chance, that is, an event without a cause or without a purpose. Every occurrence has a cause in God. Not only so, but in the ordinary affairs of this world it has a mundane cause. Further, it falls out according to the uniformity of nature.

But there are senses in which there is a chance in our world. The oldest definition of chance (τύχη) was by Anaxagoras, who makes it an event whose cause cannot be discerned by human reason (λογισμῷ). This account needs only to be a little expanded and made more definite. There are occurrences of which the cause or the law is unknown, and, in consequence, we cannot anticipate their occurrence. This may arise from the cause being utterly unknown to us. More frequently it arises from the com-

plexity of nature, from there being a number of agents working, or from the nature of their operation. We may know all the agencies at work, but we cannot tell how they are working. In all cases the events do not recur with such regularity as to constitute a law. There was a time when eclipses were regarded as coming according to no law, and men, following the law of causality, referred them to a deity. When these causes were discovered they were found to have periods, and astronomers could predict their recurrence, and they were viewed in a different light. Till lately meteors were supposed to appear capriciously, but now showers of them are expected at certain seasons of the year, and nobody ascribes them to chance. When we shake a die in a dice-box, we are acquainted with the mechanical law which it obeys in its movements, but we cannot say which side will cast up. We know, in a general way, what physiological agencies produce death, but we cannot predict at what precise time any man will die.

Still, even in such cases a certain kind and amount of truth may be had, and this from the circumstance that the event proceeds, after all, from causes which operate regularly and from there being a limited number of causes. We find that, given a sufficient number of trials, each side of the die will come up the same number of times; if any side comes up more frequently than another, we argue that the dice have been loaded. We do not know when any one man will die, but we can ascertain what number of people will die in a given time in a community.

In such cases we can strike an average, and we can foretell average results and estimate the probability of a given event. When we speak of the probability of an occurrence, we are not to understand this as implying the uncertainty of the occurrence considered in itself. The event, say the death of a person on a certain day, may be abso-

lutely sure, owing to causes operating. We can conceive that there are higher intelligences to whom it would not be uncertain. We are sure that it would not be so to the view of the Omniscient. It is so to us because of the limited nature of our faculties and of our knowledge of the causes operating. Were we cognizant of all the antecedent circumstances we might in many cases be able to predict the result. It is because of our ignorance that the event is uncertain to us. The probability or improbability is not in the event which we have for expecting it; it is subjective and not objective.

In all cases we must have certain data gained by observation and yielding a general average. In some departments we can express numerically the probability or improbability of the particular occurrence. An event reckoned impossible may be represented by 0, an event certain to happen by 1. All degrees of probability may be denoted by the fractions representing value from zero to unity. The probability of an uncertain event is represented by the number of chances favorable and unfavorable. Thus the casting up of a head or a tail being 1, and the chances against it being 2, the proper chance is one-half. The tables that have been prepared for life insurance companies have been very elaborate, but need not here be given.

There is another sense in which it may be said that there is such a thing as chance. There cannot be an occurrence without a purpose on the part of God, who has ordered the causes producing it. But there may be a concurrence without a design. It is by chance that certain rocks take the form of the face of Napoleon or Wellington. I do not know that there was any purpose designed or effected by so many men of genius being born in the year 1759, or by Cervantes dying on the same day as Shakespeare

died. There are certain minds that take the keenest interest in observing such coincidences and discover a deep meaning in what is in itself meaningless; for example, connecting a calamity with the spilling of salt at a table, or from thirteen persons meeting at that table. On the other hand, when there is an immense congregation of agents that are independent, to produce an evident benevolent end, for instance, of vibrations of light of coats, and humors, of rods and cones, to enable us to see through the eye, there is evidence of design, the chances being all against such a concurrence.

SECTION VIII.

PSYCHOLOGY.

Here, as well as in all the physical sciences, we have to begin with the observation of facts. There is, however, an important difference between the two departments. The facts in physical science are obtained by the senses; whereas, in mental science, the observing agent is self-consciousness. It is only thus we can find out what any psychical act is. An examination of the nerves and brain may show how a mental state arises, but can give no idea of the mental act itself, say of a sensation, a recollection, an imagination, of moral approbation, of emotion or wish. But in making consciousness our witness we have to allot to it a large province. We must include in it not only immediate introspection, but also the observation of the mental acts of others, as disclosed in their words, their writings, and their deeds. We cannot, indeed, look directly into the bosoms of our fellow-men so as to ascertain what is passing within, but we can gather what this is by the

expression of it, which, be it observed, we can understand because we are conscious of our own acts. History, biography, travels, plays, novels, newspapers, and especially conversation and familiar letters, may all show us human nature quite as much as they do external incidents. Without these supplements we should have a very contracted view of the mind by inspection of our own souls.

The individual facts are made known in this way. The criterion of consciousness is in itself, it is self-evidencing. As we observe the facts we distinguish between those that differ and co-ordinate them into laws. The criteria of the laws are much the same as those of physical science.

Psychology proceeds on the same two fundamental principles as physics. It is seeking for causes. Without determining the question of the freedom of the will, we may confidently affirm that causation, that the persistence of force, rules in the mind as it does in the body. Certain antecedents are sure to be followed by certain consequences. The orator urges the considerations which may persuade those whom he is addressing and lead them to action. The poet raises up images that please and elevate the mind. The father and the teacher inculcate principles which may guide the young in all their future lives. Investigators in this department have been seeking to discover faculties and the rule and mode of their operation. The early Greeks found sensation, the discursive power, and reason. Aristotle had in the soul the nutritive power sensation, memory, phantasy, and above these, the reason, active and passive. In all ages there has been a grand distinction drawn, in a loose form, between the intellect and the will, the cognitive and the motive powers. Everybody talks of the memory, the judgment, of reasoning, and of sentiment and feeling, of the power of abstracting, generalizing, distinguishing, of loving and of hating.

There seem, also, to be laws of uniformity in nature. It does not appear that in the association of ideas one idea is the cause of that which succeeds; that when height suggests hollow, and the dwarf suggests the giant, and prosperity, adversity, and a portrait the original; that when we count up from one to one hundred, there is a causal connection between the ideas—they are the joint effect of a number of causes. In the science of psychology we seek to discover these laws, such as the law of habit, the connection between the idea and the feeling raised by it, the kind of acts which conscience approves of.

Now, there may be criteria of these laws, both of causation and uniformity. These have not been so carefully enunciated as those of physical science. I believe that, *mutatis mutandis*, they may be considered as very much the same.

The Method of Agreement.—Washington is named, and we find the mind following a certain train. We think of his education, his training, the revolution, his battles, his character, all of which have been previously in the mind together, and we reach the law of contiguity, that when ideas have been in the mind at the same time, when one comes up the others are apt to follow.

The Method of Difference.—We see a portrait of Washington for the first time. The two, the portrait and Washington, were never before in the mind together, yet the portrait calls up Washington, and the law is, things that are related, especially things that are like, recall each other.

The Joint Method of Agreement and Difference.—There are days in which we find that we can easily recall the things we would remember, other days in which they will not come up. The difference is in the time: that in the first few days our brain was in perfect health; in the

other we had a headache, and we discover that the state of the brain affects our associations.

Method of Concomitant Variations.—When we are interested in an event known to us, we are apt to think of it more frequently, and we conclude that feeling, as a secondary law, influences our associations, and according to the feeling with which it is accompanied, so do ideas come up.

Method of Residues.—On contemplating kind actions, we feel a pleasure which can be explained by our social feelings; but we find that on contemplating some of these we have a feeling of moral approbation. This cannot be explained by the mere social feeling, and we have to call in a moral principle.

SECTION IX.

NATURAL THEOLOGY.

Attempts have been made to conduct this science on the joint dogmatic and deductive method, but, in my opinion, without much success. It has to deal with facts, the existence of God and the immortality of the individual soul, and therefore must have an inductive or observational element. I have my doubts whether, from a mere idea or principle in the mind, we can argue the existence of the living God. It should proceed, I reckon, mainly in the joint inductive and deductive method. It looks at God's works within and without us, and, discovering wonderful mutual fittings, means and end, traces of love and just government, it rises to the belief in a being of power, wisdom, benevolence, and justice. The inductions are collected in such works as Ray's "Wisdom of God," in Paley's

"Natural Theology," in the Bridgewater treatises, and the ordinary works of natural religion.

But there are deductive processes involved. The premises here are supplied mainly by *à priori* principles or by intuition, all to be justified by the criteria of First Truths. In the mind of man there are high and deep truths in the germ, all capable of being developed and actually working in the mature man, being called forth by the circumstances in which he is placed. There is the principle of causation, requiring us, on a new thing or a change appearing, to seek for a cause. This can stand the tests of intuition, being self-evident, necessary, universal, in our very nature and constitution, and it leads us to believe that where there are traces of design there must be a designer. There is a moral power within us, with its law and its obligations, implying a law-giver. We have not an adequate idea of infinity, but we believe that there is something beyond our widest idea or concept, something to which nothing can be added, and we are led to apply it to the powerful, the good and holy One.

We are entitled, we are required, to trust and follow these principles. They are elements and the highest elements of the reason with which we are endowed. We begin with trusting the senses, and find, as we do so, constant confirmations in our daily experience; what appeared at first to be realities we discover to be more real as we bring one sense after another to bear upon them, and find that meat nourishes us and pure air refreshes us, and the due use of the good things of this world prolongs life. We should confide in the same way in our higher ideas and beliefs, and as we do so we find them expanding and elevating the mind, opening grand vistas which look beyond the seen and temporal into the unseen and eternal. If we do not follow our lower instincts, if

we do not eat and drink, our bodies will become feeble and die; and if we deny our higher reason, our souls will lose their freshness, vigor, and aspirations.

But when we would construct the argument, indeed, in all scientific investigations and in all true philosophy we must be careful to ascertain the exact nature of the intuitions or intuitive reason we call in, and only use them accordingly. Those who neglect this are sure to present them in an extravagant form or make a perverted use of them. This has been done by the mystics of the East and of mediæval times, indeed, of all ages. Almost always they have got a glimpse of a reality, but they have seen it only under partial aspects, and they have shown it to us through a cloud, or irradiated it with reflected light, and have represented it to us as vision, inspiration, and ecstacy, whereas it is only one of the higher elevations of our nature.

All our profound thinkers have seen these truths, but have not always properly represented them. We may hold with Plato that there is a grand, indeed, a Divine idea; but I wish that idea, as in the mind, carefully examined, and its forms or law exactly determined, and it is for inductive science, and not speculation, to tell us what are the types which represent it in nature. I hold with Aristotle that there are formal and final as well as material and efficient causes in nature; but it is for a careful induction to determine the nature of these and to show how matter and force are made to work for order and for ends. I am as sure as Descartes, and as Augustine and Anselm were before him, that there is in the mind a germ of the idea of the infinite and perfect; but we must show what is the precise nature of the idea, so as to secure that we draw only legitimate inferences from it. I discover, as Leibnitz did, a pre-established harmony in nature, but it

consists mainly, not in things acting independently of each other, but in the harmony produced by things acting on each other. I attach as much importance to experience as Locke did, but I maintain that observation discovers that the intuition (which he acknowledged) looks at principles in the mind prior to all experience. I allow to Kant his forms, his categories, and his ideas, but their nature is to be discovered, not by criticism, but by induction, when they will be found not to superinduce qualities on things, but simply to enable us to perceive what is in things. I believe with Schelling in intuition (Anschauung), but it is an intuition viewing realities. I hold with Hegel that there is an Absolute, but I believe that our knowledge, after all, is finite, implying an infinite, and that the doctrine can be enunciated so as not to issue in pantheism. I turn away with scornful aversion from the pessimism of Schopenhauer and Von Hartmann, but I believe they have done good by calling attention to the existence of evil, to remove which is an end worthy of the labors and sufferings of the Son of God. I believe with Herbert Spencer in a vast unknown above, beneath, and around us, but I rejoice in a light shining in the darkness and revealing the known. I believe in the gems so rich and varied which the higher poets have left us as a rich inheritance; but before they can enter into philosophy they must be cut and set, and it will require a skilful hand to adjust them, and when they are cut it must be as skilfully as diamonds are, and this only to show more fully their form and beauty.

SECTION X.

THE SUPERNATURAL.

We have to posit the Supernatural as the origin of the natural. This we do on the principle of cause and effect. We discover in nature evidences of its being an effect. It has, as Sir John Herschel says, the appearance of "a manufactured article." This is seen particularly in the adaptation of one thing to another all throughout nature. We argue a cause above and beyond nature, and this is Supernatural.

Miracles.—It is asserted that in the very midst of the natural occurrences there are events which cannot be accounted for by natural agents. These are called miracles. Of most of these, when we examine them, we find that they cannot stand our criteria; they are the products of superstitious fears and of credulity. But there are events recorded in the Old and New Testaments which are worthy of having the tests of truth applied to them. These are not to be regarded as occurring without a cause. They are not inconsistent with the intuitive conviction of causation. They have a sufficient cause in that power in which nature originated. We are only following out the principle of causation in arguing thus. We rise to a supernatural cause because there is no agent in nature adequate to produce such occurrences as the resurrection of Lazarus or Jesus.

I would not describe miracles with Hume, as "violations of the laws of nature;" but they cannot be accounted for by these laws. They do not fall in with that general fact that every event has not only a cause in God but a cause in a physical agent. As physical agents cannot produce them, we argue that they are effected by the immediate power of God. Further, they are

not in accordance with the uniformity of nature. It is not in conformity with this that fishermen and mechanics of Galilee should produce our Lord's discourses. They accomplish their ends, in guaranteeing revealed truth, because they are above the causes and laws of nature.

The evidences of Christianity are of two kinds: one internal and the other external. The external are facts attested by witnesses, whose depositions are to be tested by the criteria of testimony. The others are those derived from the suitableness of the truth revealed to our nature, moral and spiritual, to our sinful state and our wants. Take the Sermon on the Mount as so conformable to our moral nature. Take the life and character of Jesus, so perfect, so full of love in a world of sin and selfishness. Take his sufferings and his death, so fitted to accomplish their avowed end, that is, make atonement for sin.

There is proof of a uniformity of laws in nature, not from intuition, but the combined result of the experience of all times and countries. But it can be shown that there is a like uniformity in revelation, in its types, its prophecies, its doctrines. Its miracles are of a certain kind. Those of our Lord were mostly the healing of diseases, the cure of evils. Each one is part of a system; each part bearing up the others and the whole. By the one uniformity we are sure that every event is according to law. By the other we find a conformity in a whole supernatural system.

SECTION XI.

CONCLUSION—LIMITS TO HUMAN KNOWLEDGE.

The aim of this treatise has been to show that the human mind is capable of reaching knowledge, and that it has tests to determine when it has done so. I have faced the agnostic, but have not entered into a wrestling with him, which would be endless, because he refuses to take a form by which I may lay hold of him. I have pursued a more effectual method. I have shown objects where he assures us that there is nothing. It is in this way we can command assent and gain assurance.

I have proceeded on the idea that there is a difference in the certitude of truths. Some I have shown are self-evident, necessary, and universally held, and therefore certain beyond doubt or dispute; others are only probable, some with only a slight balance in their favor, others rising to certainty. This is not so much a difference in the truths as a difference in the evidence to us. To God and to higher beings, the one kind may be as certain as the other. We cannot tell whether there will or will not be a good harvest next year. But to Omniscience it may be as certain that there is to be a good harvest as that all the angles of a triangle are equal to two right angles. It is of vast moment that we should know what kind of evidence we have, and what the validity of the evidence which we have in favor of any proposition we are required to believe, whether it is demonstrative or merely probable, and if only probable, what the degree of probability. It is also of moment that we should note what kind of truth admits of apodictic and what of only probable proof. It is vain to seek for demonstration in every kind of investigation. We can have such, as I reckon, only when we have

self-evident truth. But, then, it can be shown that inductive truth can rise to certainty. I doubt much whether we have immediate evidence of the existence of God as we have of the existence of ourselves. But we have quite as valid proof of the existence of God as we have of the existence of our fellow-men; in both we have a fact, the acts done, and we rise up by the principle of causation to a cause. The criteria of truth which I have been furnishing should assist us in all such investigations.

Man's knowledge is increasing and must continue to increase. His generalizations widen as his knowledge increases and take in more and more objects. He is constantly gaining more premises which lead to farther conclusions. One discovery leads on to another; one chamber opened shows us the door which opens into a second. Davy proved the correlation of electric and magnetic forces, Oersted of electric and magnetic, and at last the grand doctrine disclosed itself to a number of investigators, particularly to Mayer, that all the physical forces are correlated.

But man's power of discovering truth is and ever must be limited. First, there are limits to his mental powers. He has only five original inlets of knowledge into the material world. Had he fifty senses instead of five he might know vastly more. Then, his power of working on the materials required by sense and consciousness, his memory and his understanding, are also limited. Some men can discover more truth than others, and it is conceivable that there may be higher intelligences who see farther into the nature of things than the most far-sighted of men. Secondly, every man's individual experience is limited, and the same may be said of the experience of the race—it is confined within very stringent bounds.

Man can discover a vast amount of truth, speculative

and practical. We have enough revealed to exercise our faculties, to expand and elevate the mind, and to serve for all the purposes of the duty we owe to God, to ourselves, and our fellow-men. Every truth known leads, however, into the unknown. But this is to tempt us to penetrate into the unknown region that we may know it.

As we do so we shall find that there are things beyond our ken in a region beyond, above, or beneath us, and we must be content to allow them to lie there. We know as much as to know that there are truths which we cannot know. We see the objects within our proper range of vision, but we also see the darkness that encompasses them. "We know in part." Yes, we know, but we know only in part.

We who dwell in a world "where day and night alternate;" we who go everywhere accompanied by our own shadow—a shadow produced by our dark body, but produced because there is light—cannot expect to be absolutely delivered from the darkness. Man's faculties, exquisitely adapted to the sphere in which he moves, were never intended to enable him to comprehend all truth. The mind is in this respect like the eye. The eye is so constituted as to perceive things within a certain range, but as objects are removed farther and farther from us they become more indistinct, and at length are lost sight of altogether. It is the same with the intellect of man. It can penetrate a certain distance and understand certain subjects, but as they stretch away farther they look more and more confused, and at length they disappear from the view. And if the human spirit attempts to mount higher than its limited range, it will find all its flights fruitless. The dove, to use a well-known illustration of Kant's, may mount to a certain height in the heavens; but as she rises the air becomes lighter, and at length she finds that she

can no longer float upon its bosom, and should she attempt to soar higher her pinions flutter in emptiness, and she falters and falls. So it is with the spirit of man: it can wing its way a very considerable distance into the expanse above it, but there is a boundary which if it attempts to pass, it will find all its conceptions void and its ratiocinations unconnected.

Placed as we are in the centre of boundless space and in the middle of eternal ages, we can see only a few objects immediately around us, and all others fade in outline as they are removed from us by distance, till at length they lie altogether beyond our vision. And this remark holds true not only of the more ignorant, of those whose eye can penetrate the least distance; it is true also of the learned; it is perhaps true of all created beings that there is a bounding sphere of darkness surrounding the space rendered clear by the torch of science. Nay, it almost looks as if the wider the boundaries of science are pushed, and the greater the space illuminated by it, the greater in proportion the bounding sphere of darkness into which no rays penetrate, just as (to use a very old comparison) when we strike up a light in the midst of darkness, in very proportion as the light becomes stronger so does also that surface dark and black which is rendered visible.

PROGRAMME OF A PHILOSOPHIC SERIES.

For the last thirty years I have been taking my part in the philosophic discussions of the age. I have a few things yet to say before I willingly leave the arena. These have long occupied my thoughts, and they relate to thrilling topics of the day on which many are anxious to have light thrown. In order to bring my views before the thinking public, I start A PHILOSOPHIC SERIES to consist of small volumes, of about sixty pages each, in stout paper, at Fifty Cents per volume, and issued quarterly, and each embracing an exposition complete in itself of one theme. I begin with

I. THE CRITERIA OF DIVERSE KINDS OF TRUTH AS OPPOSED TO AGNOSTICISM BEING A TREATISE ON APPLIED LOGIC. — This will confront me with the leading philosophic heresy of the day, which is working secretly where it does not appear above ground and undermining some of our most precious faiths. It has been shown again and again that Agnosticism is suicidal. It is an evident contradiction to affirm that we know that we can know nothing. But when we have done all this we have only strengthened the position of Agnosticism which holds that all truth is contradictory. Without entering into a wrestling match with a spectre I have set before the mind the truth which is seen in its own light. It has again and again been shown that we have no one absolute criterion of all truth. I have allowed this and approached the subject in a different way, and I show that we have now satisfactory criteria of the diverse kinds of truth which we are required to believe. The little treatise which can be read in a few hours is intended to give assurance to thinking minds, especially young men, in this age of unsettled opinion. It may also be used as a text-book in our upper schools. It may be followed by

II. ON THE NATURE OF CAUSATION IN RELATION TO THE LATELY DISCOVERED DOCTRINE OF THE CONSERVATION OF ENERGY OR THE PERSISTENCE OF FORCE. — It is a fact that most scientific men now acknowledge that they do not know what to make of the doctrine of Causation. The old doctrine is as true as ever that every effect implies a cause, but it requires to be modified and explained anew in conformity with recent science.

III. ON WHAT DEVELOPMENT CAN DO AND WHAT IT CAN NOT DO.— Religious people in the present day do not very well know what to make of Development. Irreligious people are turning it to the worst of purposes, making it supersede the power of God. Surely some good may be done by explaining what is meant by Development which is just a form of causation, which can do much, but can not do everything.

IV. A CRITICISM OF THE PHILOSOPHY OF KANT—Specifying its truths and its errors.—Kantism is the most influential philosophy of the day both in Europe and America. Kant has established a body of most important philosophic truth, but without meaning it he has allowed principles which are fitted to undermine our knowledge and the reality of things.

V. A CRITICISM OF HERBERT SPENCER'S PHILOSOPHY AS CULMINATED IN HIS ETHICS.—Mr. Spencer is the most powerful speculative thinker of our day and we now see the full philosophic and practical issue of the principles which he has been developing for many years in eight or ten volumes. It is surely desirable to have these principles thoroughly sifted.

But I have proposed enough till such time as I find that my project is to be countenanced by the friends of a sober philosophy.

JAMES McCOSH.

CHAPTERS IN LOGIC;

CONTAINING

SIR WILLIAM HAMILTON'S LECTURES ON MODIFIED LOGIC,

AND SELECTIONS FROM

THE PORT ROYAL LOGIC.

WITH PREFACE

BY THE

REV. S. S. NELLES, D.D.,

Professor of Logic in Victoria College.

TORONTO:

THE WESLEYAN METHODIST BOOK-ROOM,

PREFACE.

THIS little volume is a reprint of Sir WILLIAM HAMILTON'S *Lectures on Modified Logic*, and of the most valuable portions of the famous *Port Royal Logic*, translated by T. S. BAYNES. The design of the publication is to provide, in cheap and convenient form, a Manual or Text-Book, on what Hamilton calls "Modified or Concrete Logic," but what others have variously designated as Applied or Practical Logic.

Whatever may be thought of the propriety of including this department of study within the science of Logic, there can be no doubt of its very great importance, and just as little doubt of its having been sadly neglected. Those who have not mastered the elements of formal or technical Logic, as well as those who have, may derive immense advantage from a careful perusal of these pages.

The merits of Sir William Hamilton are so well known, that it is perhaps unnecessary here to say anything in commendation of that part of the volume which was written by him. It may, however, be well to mention,

that his *Lectures on Modified Logic* are here given in full, without alteration either of the arrangement or the text. From the nature of their topics, they form a distinct discussion in themselves, and suffer nothing in being separated from the other lectures in which the eminent author has so ably treated of the formal laws of thought.

The other work,—the *Port Royal Logic*,—is less generally known, but is regarded by high authorities as one of the very best of the many books extant on the science of Logic. "The treatise," says Mr. Baynes, "is characterised throughout by a vigor of thought, a vivacity of criticism, a freshness and variety of illustration, an honesty and love of truth, and withal a human sympathy, which rendered it a work not only of specific scientific value, but of general interest and instruction. Logic was thus redeemed from the contempt into which it had fallen, and placed on a level with the advancing philosophy of the time."

To this may be added the testimony of Baron de Gerando, as cited by Mr. Baynes. Speaking of the parts which especially merit praise, he says,—"Above all, that beautiful Dissertation on the Origin of Prejudices, and their influence on the vices of reasoning in civil life. This Dissertation, indeed, constitutes, of itself, an entirely new Logic —one almost sufficient, and far more important than all the apparatus of the peripatetic Logic; and it must be recorded to the praise of the Port Royal writers that this is a part of their work which is peculiarly their own."

Dugald Stewart, also, in his *Dissertation on the Progress of Philosophy*, speaks of the *Port Royal Logic* as "a treatise of which it is hardly possible to estimate the merits too highly." And again:—"No publication certainly, prior to *Locke's Essay*, can be named, containing so much good sense and so little nonsense on the science of Logic; and very few have *since* appeared on the same subject which can be justly preferred to it in point of practical utility. If the author had lived in the present age, or had been less fettered by a prudent regard to existing prejudices, the technical part would probably have been reduced within a still narrower compass; but even there he has contrived to substitute, for the puerile and contemptible examples of common logicians, several interesting illustrations from the physical discoveries of his immediate predecessors; and has indulged himself in some short excursions, which excite a lively regret that he has not more frequently and freely given scope to his original reflections. Among these excursions, the most valuable, in my opinion, is *the Twentieth Chapter of the Third Part*, which deserves the attention of every logical student, as an important and instructive supplement to the enumeration of sophisms given by Aristotle."

The Editor of this compilation has confined his selections from the *Port Royal Logic* to this "twentieth chapter," which is given entire (with the exception of a few lines), and to those portions of the Preliminary Discourse which

are of general application. These selections make a suitable introduction to the Lectures of Hamilton on *Modified Logic*, and the two together furnish about the best instruction that can be had on this important branch of the science of Logic.

We live in times remarkable for the awakening and emancipation of thought. This is matter of rejoicing; but freedom of thought brings corresponding dangers and responsibilities, and we cannot do too much to aid the inquiring multitudes in the proper use of that right of private judgment of which we are so justly proud. Works like the one here presented may serve to show that all intellectual activity has its laws, the violation of which brings invariable and heavy penalties; may teach us to beware of the immoralities of the intellect; may put those who are trying to think, in the way of thinking soundly, by furnishing them with the best rules and cautions known to the world's great thinkers; and may help us forward to that "good time coming," when in moral, political, and religious affairs, men shall proceed with something like the steadiness, precision, and certainty, which have already begun to mark the pursuit of mathematical and physical science.

VICTORIA COLLEGE,
March 31st, 1870.

THE PORT-ROYAL LOGIC

CHAPTER I.

PRELIMINARY—IN WHICH THE DESIGN OF THIS NEW LOGIC IS SET FORTH.

THERE is nothing more desirable than good sense, and accuracy of thought, in discriminating between truth and falsehood. All other qualities of mind are of limited use; but exactness of judgment is of general utility in every part, and in all the employments of life. It is not alone in the sciences that it is difficult to distinguish truth from error, but also in the greater part of those subjects which men discuss in their every-day affairs. There are, in relation to almost everything, different routes—the one true, the other false—and it is reason which must choose between them. Those who choose well, are they who have minds well-regulated; those who choose ill, are those who have minds ill-regulated: and this is the first and most important difference which we find between the qualities of men's minds.

Thus the main object of our attention should be, to form our judgment, and render it as exact as possible; and to this end, the greater part of our study ought to tend. We

employ reason as an instrument for acquiring the sciences; whereas, on the contrary, we ought to avail ourselves of the sciences as an instrument for perfecting our reason—justness of mind being infinitely more important than all the speculative knowledges which we can obtain, by means of sciences the most solid and well-established. This ought to lead wise men to engage in these only so far as they may contribute to that end, and to make them the exercise only, and not the occupation, of their mental powers.

If we have not this end in view, the study of the speculative science—such as geometry, astronomy, and physics—will be little else than a vain amusement, and scarcely better than the ignorance of these things, which has at least this advantage—that it is less laborious, and affords no room for that empty vanity which is often found connected with these barren and unprofitable knowledges. These sciences not only have nooks and hidden places of very little use; they are even totally useless, considered in themselves, and for themselves alone. Men are not born to employ their time in measuring lines, in examining the relations of angles, and considering the different movements of matter; their minds are too great, their life too short, their time too precious, to be engrossed with such petty objects: but they ought to be just, equitable, prudent, in all their converse, in all their actions, and in all the business they transact; and to these things they ought specially to discipline and train themselves. This care and study are so very neccessary, that it is strange that this exactness of judgment should be so rare a quality. We find, on every side, ill-regulated minds which have scarcely any discernment of the truth; men who receive all things with a wrong bias; who allow themselves to be carried away by the slightest appearances; who are always

in excess and extremes; who have no bond to hold them firm to the truths which they know, since they are attached to them rather by chance than by any clear insight; or who, on the other hand, entrench themselves in their opinions with such obstinacy, that they will not listen to anything that may undeceive them; who determine rashly about that of which they are ignorant, which they do not understand, and which, perhaps, no one ever can understand; who make no difference between one speech and another, or judge of the truth of things by the tone of voice alone,—he who speaks fluently and impressively being in the right, he who has some difficulty in explaining himself, or displays some warmth, in the wrong: they know nothing beyond this.

Hence it is, that there are no absurdities too groundless to find supporters. Whoever determines to deceive the world, may be sure of finding people who are willing enough to be deceived; and the most absurd follies always find minds to which they are adapted. After seeing what a number are infatuated with the follies of judicial astrology, and that even grave persons treat this subject seriously, we need not be surprised at anything more. There is a constellation in the heavens which it has pleased certain persons to call the Balance, and which is as much like a balance as a windmill. The Balance is the symbol of justice; those, therefore, that are born under that constellation, will be just and equitable. There are three other signs in the zodiac, which are called, one the Ram, another the Bull, another the Goat, and which might as well have been called the Elephant, the Crocodile, and the Rhinoceros. The Ram, the Bull, and the Goat, are ruminant animals; those, therefore, who take medicines when the moon is under

these constellations, are in danger of vomiting them again. Such extravagant reasonings as these have found persons to propagate them, and others who allow themselves to be persuaded by them.

This inaccuracy of thought is the cause, not only of the errors we meet with in the sciences, but also the majority of the offences which are committed in civil life,—of unjust quarrels, unfounded lawsuits, rash counsel, and ill-arranged undertakings. There are few of these which have not their origin in some error, and in some fault of judgment, so that there is no defect which it more concerns us to correct. But this correction is as difficult of accomplishment as it is desirable, since it depends very much on the measure of intelligence with which we are endowed. Common-sense is not so common a quality as we imagine. There are a multitude of minds heavy and dull, which we cannot reform by giving them the understanding of the truth, but only by restricting them to those things which are suited to them, by withholding them from judging about those things which they are not capable of knowing. It is true, nevertheless, that a great part of the false judgment of men does not spring from this principle, but is caused solely by precipitancy of mind and want of attention, which lead us to judge rashly about that which we know only obscurely and confusedly. The little love men have for truth leads them to take no pains, for the most part, in distinguishing what is true from what is false. They allow all sorts of reasonings and maxims to enter their minds; they like better to suppose things true, than to examine them; if they do not comprehend them, they are willing to believe that others understand them well: and thus they fill the memory with a mass of things false, obscure, and unintelli-

gible, and then reason on these principles, scarcely considering at all either what they speak or what they think. Vanity and presumption contribute still more to this effect. We think it a disgrace to doubt, and to be ignorant; and we prefer rather to speak and determine at random, than to confess that we are not sufficiently informed on the subject to give an opinion. We are all of us full of ignorance and errors; and yet it is the most difficult thing in the world to obtain from the lips of man this confession, so just, and so suited to his natural state,—I am in error, and I know nothing about the matter.

We find others, on the contrary, who, having light enough to know that there are a number of things obscure and uncertain, and wishing, from another kind of vanity, to show that they are not led away by the popular credulity, take a pride in maintaining that there is nothing certain. They thus free themselves from the labour of examination, and on this evil principle they bring into doubt the most firmly established truths, and even religion itself. This is the source of Pyrrhonism [or Scepticism], another extravagance of the human mind which, though apparently opposed to the rashness of those who believe and decide everything, springs nevertheless from the same source, which is, want of attention. For as the one will not give themselves the trouble of discerning errors, the others will not look upon truth with that care which is necessary to perceive its evidence. The faintest glimmer suffices to persuade the one of things very false, and to make the other doubt of things the most certain; and in both cases it is the same want of application which produces effects so different.

True reason places all things in the rank which belongs to them; it questions those which are doubtful, rejects those

which are false, and acknowledges, in good faith, those which are evident, without being embarrassed by the vain reasons of the Pyrrhonists, which never could, even in the minds of those who proposed them, destroy the reasonable assurance we have of many things. None ever seriously doubted the existence of the sun, the earth, the moon, or that the whole was greater than its parts. We may indeed easily say outwardly with the lips that we doubt of all these things, because it is possible for us to lie; but we cannot say this in our hearts. Thus Pyrrhonism is not a sect composed of men who are persuaded of what they say, but a sect of liars. Hence they often contradict themselves in uttering their opinion, since it is impossible for their hearts to agree with their language. We see this in Montaigne, who attempted to revive this sect in the last century; for, after having said that the Academics were different from the Pyrrhonists, inasmuch as the Academics maintained that some things were more probable than others, which the Pyrrhonists would not allow, he declares himself on the side of the Pyrrhonists in the following terms: "The opinion," says he, "of the Pyrrhonists is bolder, and much more probable." There are, therefore, some things which are more probable than others. Nor was it for the sake of effect that he spoke thus: these are words which escaped him without thinking of them, springing from the depths of nature which no illusion of opinions can destroy. But the evil is, that in relation to those things which are more removed from sense, these persons, who take a pleasure in doubting everything, withhold their mind from any application, or apply it only imperfectly to that which might persuade them, and thus fall into a voluntary uncertainty in relation to the affairs of religion; for the state of darkness into which they have

brought themselves is agreeable to them, and very favourable for allaying the remorse of their conscience, and for the unrestrained indulgence of their passions. Thus, these disorders of the mind, though apparently opposed (the one leading to the inconsiderate belief of what is obscure and uncertain, the other to the doubting of what is clear and certain), have nevertheless a common origin, which is, the neglect of that attention which is necessary in order to discover the truth. It is clear, therefore, that they must also have a common remedy, and that the only way in which we can preserve ourselves from them is by fixing minute attention on our judgments and thoughts. This is the only thing that is absolutely necessary to preserve us from deceptions. For that which the Academics were wont to say,—that it was impossible to discover the truth unless we had its characters, as it would be impossible to identify a runaway slave we might be in search of, unless we had some signs by which, supposing we were to meet him, we could distinguish him from others,—is only a vain subtlety. As no marks are necessary in order to distinguish light from darkness but the light which reveals itself, so nothing else is necessary in order to recognize the truth but the very brightness which environs it, and which subdues and persuades the mind, notwithstanding all that may be said against it; so that all the reasonings of these philosophers are no more able to withhold the mind from yielding to the truth, when it is strongly imbued with it, than they are capable of preventing the eyes from seeing, when, being open, they are assailed by the light of the sun.

But since the mind often allows itself to be deceived by false appearances in consequence of not giving due attention to them, and since there are many things which cannot be

known, save by long and difficult examination, it would certainly be useful to have some rules for its guidance, so that the search after truth might be more easy and certain. Nor is it impossible to secure such rules: for since men are sometimes deceived in their judgments, and at other times are not deceived, as they reason sometimes well and sometimes ill, and as, after they have reasoned ill, they are able to perceive their error, they may thus notice, by reflecting on their thoughts, what method they have followed when they have reasoned well, and what was the cause of their error when they were deceived; and thus on these reflections form rules by which they may avoid being deceived for the future.

This is what philosophers have specially undertaken to accomplish, and in relation to which they make such magnificent promises. If we may believe them, they will furnish us, in that part which is devoted to that purpose, and which they call *logic*, with a light capable of dispelling all the darkness of the mind; they correct all the errors of our thoughts; and they give us rules so sure that they conduct us infallibly to the truth,—so necessary, that without them it is impossible to know anything with complete certainty. These are the praises which they have themselves bestowed on their precepts. But if we consider what experience shows us of the use which these philosophers make of them, both in logic and in other parts of philosophy, we shall have good grounds to suspect the truth of their promises.

Since it is not, however, just to reject absolutely the good there is in logic because of the abuse which has been made of it, and as it is not possible that all the great minds which have applied themselves with so much care to the rules of reasoning, have discovered nothing at all solid; and finally,

since custom has rendered it necessary to know (at least generally) what logic is, we believed that it would contribute something to public utility to select from the common logics whatever might best help towards forming the judgment. This is the end we specially propose to ourselves in this work ; with the view of accomplishing which, we have inserted many new reflections which have suggested themselves to our mind while writing it, and which form the greatest and perhaps the most important part of it, for it appears the common philosophers have attempted to do little more than to give the rules of good and bad reasoning. Now, although we cannot say these rules are useless, since they often help to discover the vice of certain intricate arguments, and to arrange our thoughts in a more convincing manner, still this utility must not be supposed to extend very far. The greater part of the errors of men arise, not from their allowing themselves to be deceived by wrong conclusions, but in their proceeding from false judgments, whence wrong conclusions are deduced. Those who have previously written on logic have little sought to rectify this, which is the main design of the new reflections which are to be found scattered through this book.

These, in brief, are the views we have had in writing this Logic. Perhaps, after all there are few persons who will profit by it, or be conscious of the good they have obtained, because but little attention is commonly given to putting precepts in practice by express reflections on them. But we hope, nevertheless, that those who have read it with some care may receive an impression which will render them more exact and solid in their judgments, even without their being conscious of the good, as there are some remedies

which cure diseases by increasing the vigour and fortifying the parts. Be this as it may, it cannot trouble any one long,—since those who are a little advanced may read and understand it in seven or eight days; and it will be strange if, containing so great a diversity of things, each does not find something to repay him for the trouble of a perusal.

CHAPTER II.

OF THE BAD REASONINGS WHICH ARE COMMON IN CIVIL LIFE AND IN ORDINARY DISCOURSE.

We have seen some examples of the faults which are most common in reasoning on scientific subjects; but since the principal use of reason is not in relation to those kinds of subjects which enter but little into the conduct of life, and in which there is much less danger of being deceived, it would, without doubt, be much more useful to consider generally what betrays men into the false judgments which they make on every kind of subject,—especially on that of morals, and of other things which are important in civil life, and which constitute the ordinary subject of their conversation. But, inasmuch as this design would require a separate work, which would comprehend almost all the whole of morals, we shall content ourselves with indicating here, in general, some of the causes of those false judgments which are so common amongst men.

We do not stay to distinguish false judgments from bad reasonings, and shall inquire indifferently into the causes of each,—both because false judgments are the sources of bad reasonings, and produce them as a necessary consequence, and because in reality there is almost always a concealed and enveloped reasoning in what appears to be a simple judgment, there being always something which operates on

the motive and principle of that judgment. For example, when we judge that a stick which appears bent in the water is really so, this judgment is founded on that general and false proposition, that what appears bent to our senses is so really, and thus contains an undeveloped reasoning.

In considering them generally, the causes of our errors appear to be reducible to two principles: the one internal —the *irregularity of the will*, which *troubles and disorders the judgment;* the other external, which lies in the *objects of which we judge*, and which deceive our minds by *false appearances*. Now although these causes almost always appear united together, there are nevertheless certain errors, in which one prevails more than the other; and hence we shall treat of them separately.

OF THE SOPHISMS OF SELF-LOVE, OF INTEREST, AND OF PASSION.

I.

If we examine with care what commonly attaches men rather to one opinion than to another, we shall find that it is not a conviction of the truth, and the force of the reasons, but some bond of self-love, of interest, or of passion. This is the weight which bears down the scale, and which decides us in the greater part of our doubts. It is this which gives the greatest impetus to our judgments, and which holds us to them most forcibly. We judge of things, not by what they are in themselves, but by what they are in relation to us, and truth and utility are to us but one and the same thing.

No other proofs are needed than those which we see every day, to show that the things which are held everywhere else as doubtful, or even as false, are considered most certain

by all of some one nation, or profession, or institution. For, since it cannot be that what is true in Spain should be false in France, nor that the minds of all Spaniards are so differently constituted from those of Frenchmen, as that, judging by the same rules of reasoning, that which appears generally true to the one should appear generally false to the others, it is plain that this diversity of judgment can arise from no other cause except that the one choose to hold as true that which is to their advantage; and that the others, having no interest at stake, judge of it in a different way.

Nevertheless, what can be more unreasonable than to take our interest as the motive for believing a thing? All that it can do, at most, is to lead us to consider with more attention the reasons which may enable us to discover the truth of that which we wish to be true; but it is only the truth which must be found in the thing itself, independently of our desires, which ought to convince us. I am of such a country; therefore I must believe that such a saint preached the gospel there. I am of such an order; therefore I must believe that such a privilege is right. These are no reasons. Of whatever order, and of whatever country you may be, you ought to believe only what is true; and what you would have been disposed to believe, though you had been of another country, of another order, and of another profession.

II.

But this illusion is much more evident when any change takes place in the passions; for, though all things remain in their place, it appears, nevertheless, to those who are moved by some new passion, that the change which has taken place in their own heart alone has changed all external things which have any relation to them. How often do we see

persons who are able to recognize no good quality, either natural or acquired, in those against whom they have conceived an aversion, or who have been opposed in something to their feelings, desires, and interests! This is enough to render them at once, in their estimation, rash, proud, ignorant, without faith, without honour, and without conscience. Their affections and desires are not any more just or moderate than their hatred. If they love any one, he is free from every kind of defect. Everything which they desire is just and easy, everything which they do not desire is unjust and impossible, without their being able to assign any other reason for all these judgments than the passion itself which possesses them; so that, though they do not expressly realize to their mind this reasoning: I love him; therefore, he is the cleverest man in the world: I hate him; therefore, he is nobody;—they realize it to a great extent in their hearts; and therefore, we may call sophisms and delusions of the heart those kinds of errors which consist in transferring our passion to the objects of our passions, and in judging that they are what we will or desire that they should be; which is without doubt very unreasonable, since our desires can effect no change in the existence of that which is without us, and since it is God alone whose will is efficacious enough to render all things what he would have them to be.

III.

We may reduce to the same illusion of self-love that of those who decide everything by a very general and convenient principle, which is, that they are right, that they know the truth; from which it is not difficult to infer that those who are not of their opinion are deceived,—in fact, the conclusion is necessary.

The error of these persons springs solely from this, that the good opinion which they have of their own insight leads them to consider all their thoughts as so clear and evident, that they imagine the whole world must accept them as soon as they are known. Hence it is that they so rarely trouble themselves to furnish proofs,—they seldom listen to the opinions of others, they wish all to yield to their authority, since they never distinguish their authority from reason. They treat with contempt all those who are not of their opinion, without considering that if others are not of their opinion, so neither are they of the opinion of others, and that it is unjust to assume, without proof, that we are in the right when we attempt to convince others, who are not of our opinion, simply because they are persuaded that we are not in the right.

IV.

There are some, again, who have no other ground for rejecting certain opinions than this amusing reasoning:—If this were so, I should not be a clever man; now, I am a clever man; therefore, it is not so. This is the main reason which, for a long time, led to the rejection of some most useful remedies, and most certain discoveries; for those who had not known them previously fancied that, by admitting them, they would have confessed themselves to have been hitherto deceived. "What," said they, "if the blood circulate; if the food is not carried to the liver by the mesaraic veins; if the venous artery carry the blood to the heart; if the blood rise by the descending hollow vein; if nature does not abhor a vacuum; if the air be heavy and have a movement below,—I have been ignorant of many important things in anatomy and in physics.

these things, therefore, cannot be." But, to remedy this folly, it is only necessary to represent fully to such, that there is very little discredit in being mistaken, and that they may be accomplished in other things, though they be not in those which have been recently discovered.

V.

There is, again, nothing more common than to see people mutually casting on each other the same reproaches, and accusing one another—for example, of obstinacy, passion, and chicanery—when they are of different opinions. There are scarcely any advocates who do not accuse each other of delaying the process, and concealing the truth by artifices of speech; and thus those who are in the right, and those who are in the wrong, with almost the same language make the same complaints, and attribute to each other the same vices. This is one of the most injurious things possible in the life of men, for it throws truth and error, justice and injustice, into an obscurity so profound, that the world, in general, cannot distinguish between them; and hence it happens, that many attach themselves, by chance and without knowledge, to one of these parties, and that others condemn both as being equally wrong.

All this confusion springs, again, from the same malady which leads each one to take, as a principle, that he is in the right; for from this it is not difficult to infer, that all who oppose us are obstinate, since to be obstinate is not to submit to the right.

But still, although it be true that these reproaches of passion, of blindness, and of quibbling, which are very unjust on the part of those who are mistaken, are just and right on the part of those who are not so; nevertheless,

since they assume that truth is on the side of him who makes them, wise and thoughtful persons, who treat of any contested matter, should avoid using them, before they have thoroughly established the truth and justice of the cause which they maintain. They will never then accuse their adversaries of obstinacy, of rashness, of wanting common sense, before they have clearly proved this. They will not say, before they have shown it, that they fall into intolerable absurdities and extravagances; for the others, on their side, will say the same of them, and thus accomplish nothing. And thus they will prefer rather to observe that most equitable rule of St. Augustine:—*Omittamus ista communia, quæ dici ex utraque parte possunt, licet vere dici ex utraque parte non possint.* They will thus be content to defend truth by the weapons which are her own, and which falsehood cannot borrow. These are clear and weighty reasons.

VI.

The mind of man is not only in love with itself, but it is also naturally jealous, envious of and ill-disposed towards others. It can scarcely bear that they should have any advantage, but desires it all for itself; and as it is an advantage to know the truth, and furnish men with new views, a secret desire arises to rob those who do this of the glory, which often leads men to combat, without reason, the opinions and inventions of others.

Thus, as self-love often leads us to make these ridiculous reasonings: It is an opinion which I discovered, it is that of my order, it is an opinion which is convenient; it is, therefore, true; natural ill-will leads us often to make these others, which are equally absurd: Some one else said such

a thing; it is, therefore, false: I did not write that book; it is, therefore, a bad one.

This is the source of the spirit of contradiction so common amongst men, and which leads them, when they hear or read anything of another, to pay but little attention to the reasons which might have persuaded them, and to think only of those which they think may be offered against it; they are always on their guard against truth, and think only of the means by which it may be repressed and obscured—in which they are almost invariably successful, the fertility of the human mind in false reasons being inexhaustible.

When this vice is in excess, it constitutes one of the leading characteristics of the spirit of pedantry, which finds its greatest pleasure in quibbling with others on the pettiest things, and in contradicting everything with a pure malignity. But it is often more imperceptible and concealed; and we may say, indeed, that no one is altogether free from it, since it has its root in self-love, which always lives in men.

The knowledge of this malignant and envious disposition, which dwells deep in the heart of men, shows us that one of the most important rules which we can observe, in order to win those to whom we speak from error, and bring them over to the truth of which we would persuade them, is to excite their envy and jealousy as little as possible by speaking of ourselves, and the things which concern us.

For, since men love scarcely any but themselves, they cannot bear that another should intrude himself upon them, and thus throw into shade the main object of their regard. All that does not refer to themselves is odious and impertinent, and they commonly pass from the hatred of the man to the hatred of his opinions and reasons. Hence, wise persons avoid as much as possible revealing to others the

advantages which they have; they avoid attracting attention to themselves in particular; and seek rather, by hiding themselves in the crowd, to escape observation, in order that the truth which they propose may be seen alone in their discourse.

The late M. Pascal, who knew as much of true rhetoric as any one ever did, carried this rule so far as to maintain that a well-bred man ought to avoid mentioning himself, and even to avoid using the words *I* and *me;* and he was accustomed to say, on this subject, that Christian piety annihilated the human *me*, and that human civility concealed and suppressed it. This rule, however, is not to be observed too rigidly, for there are many occasions on which it would uselessly embarrass us to avoid these words; but it is always good to keep it in view, in order to preserve us from the wretched custom of some individuals, who speak only of themselves, and who quote themselves continually, when their opinion is not asked for. This leads those who hear them to suspect that this constant recurrence to themselves arises only from a secret pleasure, which leads them continually to that object of their love, and thus excites in them, by a natural consequence, a secret aversion to these people, and towards all that they say. This shows us that one of the characteristics most unworthy of a sensible man is that which Montaigne has affected in entertaining his readers with all his humours, his inclinations, his fancies, his maladies, his virtues, and his vices, which could arise only from a weakness of judgment, as well as a violent love for himself. It is true that he attempted, as far as possible, to remove from himself the suspicion of a low and vulgar vanity, by speaking freely of his defects, as well as of his good qualities, which has something amiable in it, from the appear-

ance of sincerity; but it is easy to see that all this is only a trick and artifice; which should only render it still more odious. He speaks of his vices in order that they may be known, not that they may be detested; he does not think for a moment that he ought to be held in less esteem; he regards them as things very indifferent, and rather as creditable than disgraceful; if he reveals them it gives him no concern, and he believes that he will not be, on that account, at all more vile or contemptible. But when he apprehends that anything will degrade him at all, he is as careful as any one to conceal it; hence, a celebrated author of the present day pleasantly remarks, that though he takes great pains, without any occassion, to inform us, in two places of his book, that he had a page, (an officer of very little use in the house of a gentleman of six thousand livres a-year) he has not taken the same pains to inform us that he had also a clerk, having been himself counsellor of the parliament of Bordeaux. This employment, though very honourable in itself, did not satisfy the vanity he had of appearing always with the air of a gentleman and of a cavalier, and as one unconnected with the brief and gown.

It is nevertheless probable, however, that he would not have concealed this circumstance of his life if he could have found some Marshal of France who had been counsellor of Bordeaux, as he has chosen to inform us that he had been mayor of that town, but only, after having informed us that he had succeeded Marshal De Biron in that office, and had been succeeded by Marshal De Matignon.

But the greatest vice of this author is not that of vanity, for he is filled with such a multitude of shameful scandals, and of epicurean and impious maxims, that it is wonderful that he has been endured so long by everybody, and

that there are even men of mind who have not discovered the poison.

No other proofs are necessary, in order to judge of his libertinism, than that very manner even in which he speaks of his vices; for allowing, in many places, that he had been guilty of a great number of criminal excesses, he declares, nevertheless, that he did not repent of them at all, and that if he had to live over again he would live as he had done. "As for me," says he, "I cannot desire in general to be other than I am. I cannot condemn my universal form, though I may be displeased with it, and pray God for my entire reformation, and for the pardon of my natural weakness; but this I ought not to call repentance any more than the dissatisfaction I may feel at not being an angel, or Cato; my actions are regulated and conformed to my state and condition; I cannot be better, and repentance does not properly refer to things which are not in our power. I never expected incongruously to affix the tail of a philosopher to the head and body of an abandoned man, or that the meagre extremity of my life was to disavow and deny the most beautiful, complete, and largest portion of the whole. If I had to live over again I would live as I have done; I do not lament over the past; I do not fear for the future." Awful words, which denote the entire extinction of all religious feeling, but which are worthy of him who said also, in another place: "I plunge myself headlong blindly into death, as into a dark and silent abyss, full of a mighty sleep, full of unconsciousness and lethargy, which engulphs me at once, and overwhelms me in a moment." And in another place: "Death, which is only a quarter of an hour's passion, without consequence, and without injury, does not deserve any special precepts."

Although this digression appears widely removed from this subject, it belongs to it nevertheless, for this reason—that there is no book which more fosters that bad custom of speaking of one's self, being occupied with one's self, and wishing all others to be so too. This wonderfully corrupts reason, both in ourselves, through the vanity which always accompanies these discourses, and in others, by the contempt and aversion which they conceive for us. Those only may be allowed to speak of themselves who are men of eminent virtue, and who bear witness by what means they have become so, so that if they make known their good actions, it is only to excite others to praise God for these, or to instruct them; and if they publish their faults, it is only to humble themselves before men, and to deter them from committing these. But for ordinary persons it is a ridiculous vanity to wish to inform others of their petty advantages; and it is insufferable effrontery to reveal their excesses to the world without expressing their sorrow for them, since the last degree of abandonment in vice is, not to blush for it, and to have no concern or repentance on account of it, but to speak of it indifferently as of anything else; in which mainly lies the wit of Montaigne.

VII.

We may distinguish to some extent from malignant and envious contradiction another kind of disposition not so bad, but which produces the same faults of reasoning; this is the spirit of debate, which is, however, a vice very injurious to the mind.

It is not that discussions, generally, can be censured. We may say on the contrary that, provided they be rightly used, there is nothing which contributes more towards

giving us different hints, both for finding the truth, and for recommending it to others. The movement of the mind, when it works alone in the examination of any subject, is commonly too cold and languid. It needs a certain warmth to inspire it, and awaken its ideas, and it is commonly through the varied opposition which we meet with that we discover wherein the obscurity and the difficulties of conviction consist, and are thus led to endeavor to overcome them.

It is true, however, that just in proportion as this exercise is useful when we employ it aright, and without any mixture of passion, so, in that proportion, is it dangerous when we abuse it, and pride ourselves on maintaining our opinion at whatever cost, and in contradicting that of others. Nothing can separate us more widely from the truth, and plunge us more readily into error, than this kind of disposition. We become accustomed, unconsciously, to find reasons for everything, and to place ourselves above reason by never yielding to it, which leads us by degrees to hold nothing as certain, and to confound truth with error, in regarding both as equally probable. This is why it is so rare a thing for a question to be determined by discussion; and why it scarcely ever happens that two philosophers agree. They always find replies and rejoinders, since their aim is to avoid not error but silence, and since they think it less disgraceful to remain always in error than to avow that they are mistaken.

Thus, unless at least we have been accustomed by long discipline to retain the perfect mastery over ourselves, it is very difficult not to lose sight of truth in debates, since there are scarcely any exercises which so much arouse our passions. What vices have they not excited, says a cele-

brated author [Montaigne], being almost always governed by anger! We pass first to a hatred of the reasons, and then of the persons. We learn to dispute only to contradict; and each contradicting and being contradicted, it comes to pass that the result of the debate is the annihilation of truth. One goes to the east and another to the west—one loses the principle in dispute, and another wanders amidst a crowd of details—and after an hour's storm, they know not what they were discussing. One is above, another below, and another at the side—one seizes on a word or similitude—another neither listens to, nor at all understands what his opponent says, and is so engaged with his own course that he only thinks of following himself, not you.

There are some, again, who, conscious of their weakness, fear everything, refuse everything, confuse the discussion at the onset, or in the midst of it, become obstinate, and are silent, affecting a proud contempt, or a stupid modesty of avoiding contention. One, provided only that he is striking, cares not how he exposes himself—another counts his words and weighs his reasons—a third relies on his voice and lungs alone. We see some who conclude against themselves, and others who weary and bewilder everyone with prefaces and useless digressions. Finally, there are some who arm themselves with abuse, and make a German quarrel in order to finish the dispute with one who has worsted them in argument. These are the common vices of our debates, which are ingeniously enough represented by this writer,* who, without ever having known the true grandeur of man, has sufficiently canvassed his defects.

* The greater part of this page is taken directly from Montaigne, *Essays* iii. 8. His sentiments are here referred to with approbation; and it would have been but fair, since when quoted for condemna-

We may hence judge how liable these kinds of conferences are to disorder the mind, at least unless we take great care not only not to fall ourselves first into these errors, but also not to follow those who do, and so to govern ourselves that we may see them wander without wandering ourselves, and without losing the end we ought to seek, which is the elucidation of the truth under discussion.

VIII.

We find some persons, again, principally amongst those who attend at court, who, knowing very well how inconvenient and disagreeable these controversial dispositions are, adopt an immediately opposite course, which is that of contradicting nothing, but of praising and approving everything indifferently. This is what is called complaisance, which is a disposition convenient enough indeed for our fortune, but very injurious to our judgment, for as the controversial hold as true the contrary of what is said to them, the complaisant appear to take as true everything which is said to them, and this habit corrupts, in the first place, their discourse, and then their minds.

Hence it is that praises are become so common, and are given so indifferently to everyone, that we know not what to conclude from them. There is not a single preacher in the "Gazette," who is not most eloquent, and who does not ravish his hearers by the profundity of his knowledge. All who die are illustrious for piety; and the pettiest authors

---

tion he is always mentioned by name, that he should here also have been expressly referred to. The gay and easy scepticism of Montaigne, however, so offended the moral earnestness of the Port-Royal writers, that they can scarcely allow him any merit; and rarely, when referring to him, do him justice.

might make books of praises which they receive from their friends. So that, amidst this profusion of praises, which are made with such little discernment, it is matter of wonder that there are found some so eager for them, and who treasure them so carefully when given.

It is quite impossible that this confusion in the language should not produce some confusion in the mind, for those who adopt the habit of praising everything, become accustomed also to approve of everything. But though the falsehood were only in the words, and not in the mind, this would be sufficient to lead those who sincerely love the truth to avoid it. It is not necessary to reprove everything which may be bad, but it is necessary to praise only what is truly praiseworthy, otherwise we lead those whom we praise in this way into error. We help to deceive those who judge of their persons by these praises; and we commit a wrong against those who truly deserve praises, by giving them equally to those who do not deserve them. Finally, we destroy all the trustworthiness of language, and confuse all ideas and words, by causing them to be no longer signs of our judgments and thoughts, but simply an outward civility which we give to those whom we praise as we might do a bow, for this is all that we can infer from ordinary praises and compliments.

IX.

Amongst the various ways by which self-love plunges men into error, or rather strengthens them in it, and prevents their escape from it, we must not forget one which is without doubt among the principal and most common. This is the engaging to maintain any opinion, to which we may attach ourselves from other considerations than those

of its truth. For this determination to defend our opinion leads us no longer to consider whether the reasons we employ are true or false, but whether they will avail to defend that which we maintain. We employ all sorts of reasons, good or bad, in order that there may be some to suit every one; and we sometimes proceed even to say things which we well know to be absolutely false, if they will contribute to the end which we seek. The following are some examples:—

An intelligent man would hardly ever suspect Montaigne of having believed all the dreams of judicial astrology. Nevertheless, when he needs them for the purpose of foolishly degrading mankind, he employs them as good reasons. "When we consider," says he, "the dominion and power which these bodies have, not only on our lives, and on the state of our fortune, but also on our inclinations, which are governed, driven, and disturbed, according to their influences, how can we deprive them of a soul, of life, and of discourse?"

Would he destroy the advantages which men have over beasts through the intercourse of speech, he relates to us absurd stories, whose extravagance no one knew better than himself, and derives from them these still more absurd conclusions:—"There have been," says he, "some who boasted that they understood the language of brutes, as Appollonious Thyaneous, Melampus, Tiresias, Thales, and others; and since what the cosmographers say is true, that there are some nations which receive a dog as their king, they must give a certain interpretation to his voice and movements." [Essays, ii. 12.]

We might conclude, for the same reason, that when Caligula made his horse consul, the orders which he gave

in the discharge of that office must have been clearly understood. But we should do wrong in accusing Montaigne of this bad consequence; his design was not to speak reasonably, but to gather together a confused mass of everything which might be said against men, which is, however, a vice utterly opposed to the justness of mind and sincerity of a good man.

Who, again, would tolerate this other reasoning of the same author on the subject of the auguries which the pagans made from the flight of birds, and which the wisest amongst them derided? "Amongst all the predictions of time past," says he, "the most ancient, and the most certain, were those which were derived from the flight of birds. We have nothing of the like kind—nothing so admirable; that rule, that order of the moving of the wing, through which the consequences of things to come were obtained, must certainly have been directed by some excellent means to so noble an operation; for it is insufficient to attribute so great an effect to some natural ordinance, without the intelligence, agreement, or discourse of the agent which produces it; and such an opinion is evidently false." [Essays, ii. 12.]

Is it not a delightful thing to see a man who holds that nothing is either evidently true or evidently false, in a treatise expressly designed to establish Pyrrhonism, and to destroy evidence and certainty, deliver to us seriously these dreams as certain truths, and speak of the contrary opinion as evidently false? But he is amusing himself at our expense when he speaks in this way, and he is without excuse in thus sporting with his readers, by telling them things which he does not, and could not without absurdity, believe.

He was, without doubt, as good a philosopher as Virgil, who does not ascribe to any intelligence in the birds even those periodical changes which we observe in their movement according to the difference of the air, from which we may derive some conjecture as to rain and fine weather.

But these mistakes being voluntary, all that is necessary to avoid them is a little good faith. The most common, and the most dangerous, are those of which we are not conscious, because the engagement into which we have entered to defend an opinion disturbs the view of the mind, and leads it to take as true that which contributes to its end. The only remedy which can be applied to these is to have no end but truth, and to examine reasonings with so much care, that even prejudice shall not be able to mislead us.

CHAPTER III.

OF THE FALSE REASONINGS WHICH ARISE FROM OBJECTS THEMSELVES.

We have already noticed that we ought not to separate the inward causes of our errors from those which are derived from objects, which may be called the outward, because the false appearance of these objects would not be capable of leading us into error, if the will did not hurry the mind into forming a precipitate judgment, when it is not as yet sufficiently enlightened.

Since, however, it cannot exert this power over the understanding in things perfectly evident, it is plain that the obscurity of the objects contributes somewhat to our mistakes; and, indeed, there are often cases in which the passion which leads us to reason ill is almost imperceptible. Hence it is useful to consider separately those illusions which arise principally from the things themselves :—

I.

It is a false and impious opinion, that truth is so like to falsehood, and virtue to vice, that it is impossible to distinguish between them; but it is true that, in the majority of cases, there is a mixture of truth and error, of virtue and vice, of perfection and imperfection, and that this mixture is one of the most ordinary sources of the false judgments of men.

For it is through this deceptive mixture that the good qualities of those whom we respect lead us to approve of their errors, and that the defects of those whom we do not esteem lead us to condemn what is good in them, since we do not consider that the most imperfect are not so in everything, and that God leaves in the best imperfections, which, being the remains of human infirmity, ought not to be the objects of our respect or imitation.

The reason of this is, that men rarely consider things in detail ; they judge only according to their strongest impression, and perceive only what strikes them most ; thus, when they perceive a good deal of truth in a discourse, they do not notice the errors which are mixed with it ; and, on the contrary, when the truths are mingled with many errors, they pay attention only to the errors,—the strong bears away the weak, and the most vivid impression effaces that which is more obscure.

It is, however, a manifest injustice to judge in this way. There can be no possible reason for rejecting reason, and truth is not less truth for being mixed with error. It does not belong to men, although men may propound it. Thus, though men, by reason of their errors, may deserve to be condemned, the truth which they advance ought not to be rejected.

Thus justice and truth require, that in all things which are thus made up of good and evil we distinguish between them ; and in this wise separation it is that mental precision mainly appears. Hence the fathers of the church have taken from pagan books very excellent things for their morals, and thus St. Augustine has not scrupled to borrow from a heretical Donatist seven rules for interpreting Scripture.

Reason obliges us, when we can, to make this distinction; but since we have not always time to examine in detail the good and evil that may be in everything, it is right, in such circumstances, to give to them the name which they deserve from their preponderating element. Thus we ought to say that a man is a good philosopher who commonly reasons well, and that a book is a good book which has notoriously more of good than of evil in it.

Men, however, are very much deceived in these general judgments; for they often praise and blame things from the consideration only of what is least important in them,—want of penetration leading them not to discover what is most important, when it is not the most striking: thus, although those who are wise judges in painting value infinitely more design than colour, or delicacy of touch, the ignorant are, nevertheless, more impressed by a painting whose colours are bright and vivid, than by another more sober in colour, however admirable in design.

It must, however, be confessed, that false judgments are not so common in the arts, since those who know nothing about them defer more readily to the opinion of those who are well informed; but they are most frequent in those things which lie within the jurisdiction of the people, and of which the world claims the liberty of judging, such as eloquence.

We call, for example, a preacher eloquent, when his periods are well turned, and when he uses no inelegant words; and from this M. Vaugelas says, in one place, that a bad word does a preacher or an advocate more harm than a bad reasoning. We must believe that this is simply a truth of fact which he relates, and not an opinion which he supports. It is true that we find people who judge in

this way, but it is true also that there is nothing more unreasonable than these judgments; for the purity of language, and the multitude of figures, are but to eloquence what the colouring is to a painting—that is to say, only its lower and more sensuous part; but the most important part consists in conceiving things forcibly, and in expressing them so that we may convey to the minds of the hearers a bright and vivid image, which shall convey these things not only in an abstract form, but with the emotions also with which we conceive them; and this we may find in men of inelegant speech and unbalanced periods, while we meet with it rarely in those who pay so much attention to words and embellishments, since this care distracts their attention from things, and weakens the vigor of their thoughts,—as painters remark, that those who excel in colours do not commonly excel in design—the mind not being capable of this double application, and attention to the one injuring the other.

We may say, in general, that the world values most things by the exterior alone, since we find scarcely any who penetrate to the interior and to the foundation of them; everything is judged according to the fashion, and unhappy are those who are not in favour. Such a one is clever, intelligent, profound, as much as you will, but he does not speak fluently, and cannot turn a compliment well; he may reckon on being little esteemed through the whole of his life by the generality of the world, and on seeing a multitude of insignificant minds preferred before him. It is no great evil not to have the reputation which we merit, but it is a vast one to follow these false judgments, and to judge of things only superficially; and this we are bound, as far as possible, to avoid.

II.

Amongst the causes which lead us into error by a false lustre, which prevents our recognising it, we may justly reckon a certain grand and pompous eloquence, which Cicero calls *abundantem sonantibus verbis uberibusque sententiis;* for it is wonderful how sweetly a false reasoning flows in at the close of a period which well fits the ear, or of a figure which surprises us by its novelty, and in the contemplation of which we are delighted.

These ornaments not only veil from our view the falsehoods which mingle with discourse, but they insensibly engender them, since it often happens that they are necessary to the completion of the period or the figure. Thus, when we hear an orator commencing a long gradation, or an antithesis of many members, we have reason to be on our guard, since it rarely happens that he finishes without exaggerating the truth, in order to accommodate it to the figure. He commonly disposes of it as we do the stones of a building, or the metal of a statue: he cuts it, lengthens it, narrows it, disguises it, as he thinks fit, in order to adapt it to that vain work of words which he wishes to make.

How many false thoughts has the desire of making a good point produced! How many have been led into falsehood for the sake of a rhyme! How many foolish things have certain Italian authors been led to write, through the affectation of using only Ciceronian words, and of what is called pure Latinity! Who could help smiling to hear [Cardinal] Bembo say that a pope had been elected by the favour of the immortal gods—*Deorum immortalium beneficiis?* There are poets even who imagine that the essence of poetry consists in the introduction of pagan divinities; and a German poet, a good versifier enough, though

not a very judicious writer, having been justly reproached by Francis Picus Mirandola with having introduced into a poem, where he describes the wars of Christians against Christians, all the divinities of paganism, and having mixed up Apollo, Diana, and Mercury, with the pope, the electors, and the emperor, distinctly maintained that, without this, it would not have been a poem,—in proof of which he alleged this strange reason, that the poems of Hesoid, of Homer, and of Virgil, are full of the names and the fables of these gods; whence he concluded that he might be allowed to do the same.

These bad reasonings are often imperceptible to those who make them, and deceive them first. They are deafened by the sound of their own words, dazzled with the lustre of their figures; and the grandeur of certain words attaches them unconsciously to thoughts of little solidity, which they would doubtless have rejected had they exercised a little reflection.

It is probable, for instance, that it was the word vestal which pleased an author of our time, and which led him to say to a young lady, to prevent her from being ashamed of knowing Latin, that she need not blush to speak a language which had been spoken by the vestals. For, if he had considered this thought, he would have seen that he might as justly have said to that lady that she ought to blush to speak a language which had been formerly spoken by the courtezans of Rome, who were far more numerous than the vestals; or that she ought to blush to speak any other language than that of her own country, since the ancient vestals spoke only their natural language. All these reasonings, which are worth nothing, are as good as that of this author;

and the truth is, that the vestals have nothing to do with justifying or condemning maidens who learn Latin.

The false reasonings of this kind, which are met with continually in the writings of those who most affect eloquence, show us how necessary it is for the majority of those who write or speak to be thoroughly convinced of this excellent rule,—*that there is nothing beautiful except that which is true;* which would take away from discourse a multitude of vain ornaments and false thoughts. It is true that this precision renders the style more dry and less pompous; but it also renders it clearer, more vigorous, more serious, and more worthy of an honourable man. The impression which it makes is less strong, but much more lasting; whereas that produced by these rounded periods is so transient, that it passes away almost as soon as we have heard them.

III.

It is a very common defect amongst men to judge rashly of the actions and intentions of others; and they almost always fall into it by a bad reasoning, through which, in not recognising with sufficient clearness all the causes which might produce any effect, they attribute that defect definitely to one cause, when it may have been produced by many others; or, again, suppose that a cause, which has accidentally, when united with many circumstances, produced an effect on one occasion, must do so on all occcasions.

A man of learning is found to be of the same opinion with a heretic, in a matter of criticism, independent of religious controversies: a malicious adversary concludes from this that he is favourable to heretics; but he concludes this rashly and maliciously, since it is perhaps reason and truth which have led him to adopt that opinion.

A writer may speak with some strength against an opinion which he believes to be dangerous; he will, from this, be accused of hatred and animosity against the authors who have advanced it; but he will be so unjustly and rashly, since this earnestness may arise from zeal for the truth, just as well as from hatred of the men who oppose it.

A man is the friend of a vicious man: it is, therefore, concluded that he is connected by some bond of interest with him, and is a partaker in his crimes. This does not follow: perhaps he knows nothing about them; and perhaps he has no part in them.

We fail to render true civility to those to whom it is due: we are said to be proud and insolent; but this was perhaps only an inadvertence or simple forgetfulness.

All exterior things are but equivocal signs, that is to say, signs which may signify many things; and we judge rashly when we determine this sign to mean a particular thing, without having any special reason for doing so. Silence is sometimes a sign of modesty and wisdom, and sometimes of stupidity. Slowness sometimes indicates prudence, and sometimes heaviness of mind. Change is sometimes a sign of inconstancy, and sometimes of sincerity. Thus it is bad reasoning to conclude that a man is inconstant, simply from the fact that he has changed his opinion; for he may have a good reason for changing it.

IV.

The false inductions by which general propositions are derived from some particular experiences, constitute one of the most common sources of the false reasonings of men. Three or four examples suffice them to make a *maxim* and a *common-place*, which they then employ as a principle fo deciding all things.

There are many maladies hidden from the most skilful physicians, and remedies often do not succeed: rash minds hence conclude that medicine is absolutely useless, and only a craft of charlatans.

There are light and loose women: this is sufficient for the jealous to conceive unjust suspicions against the most virtuous, and for licentious writers to condemn all universally.

There are some persons who hide great vices under an appearance of piety; libertines conclude from this that all devotion is no better than hypocrisy.

There are some things obscure and hidden, and we are often grossly deceived: all things are obscure and uncertain, say the ancient and modern Pyrrhonists, and we cannot know the truth of anything with certainty.

There is a want of equality in some of the actions of men, and this is enough to constitute a common-place, from which none are exempt. "Reason," say they, "is so weak and blind, that there is nothing so evidently clear as to be clear enough for it; the easy and the hard are both alike to it; all subjects are equal, and nature in general disclaims its jurisdiction. We only think what we *will* in the very moment in which we *will* it; we will nothing freely, nothing absolutely, nothing constantly."

Most people set forth the defects or good qualities of others only by general and extreme propositions. From some particular actions we infer a habit: from three or four faults we conclude a custom; and what happens once a month or once a year, happens every day, at every hour, and every moment, in the discourses of men,—so little pains do they take to observe in them the limits of truth and justice.

V.

It is a weakness and injustice which we often condemn, but which we rarely avoid, to judge of purposes by the event, and to reckon those who had taken a prudent resolution according to the circumstances, so far as they could see them, guilty of all the evil consequences which may have happened therefrom, either simply through accident, or through the malice of others who had thwarted it, or through some other circumstances which it was impossible for them to foresee.

Men not only love to be fortunate as much as to be wise, but they make no distinction between the fortunate and the wise, nor between the unfortunate and the guilty. This distinction is too subtile for them. We are ingenious in finding out the faults which we imagine have produced the want of success; and as astrologers, when they know a given event, fail not to discover the aspect of the stars which produced it, so also we never fail to find, after disgraces and misfortune, that those who have met with them have deserved them by some imprudence. He is unsuccessful, therefore he is in fault. In this way the world reasons, and in this way it has always reasoned, because there has always been little equity in the judgments of men, and because, not knowing the true causes of things, they substitute others according to the event, by praising those who are successful, and blaming those who are not.

VI.

But there are no false reasonings more common amongst men than those into which they fall, either by judging rashly of the truth of things from some authority insuffi-

cient to assure them of it, or by deciding the inward essence by the outward manner. We call the former the sophism of authority, the latter the sophism of the manner.

To understand how common these are, it is only necessary to consider that the majority of men are determined to believe one opinion rather than another, not by any solid and essential reasons which might lead them to know the truth, but by certain exterior and foreign marks which are more consonant to, or which they judge to be consonant to, truth, than to falsehood.

The reason of this is, that the interior truth of things is often deeply hidden; that the minds of men are commonly feeble and dark, full of clouds and false light, while their outward marks of truth are clear and sensible; so that, as men naturally incline to that which is easiest, they almost always range themselves on the side where they see those exterior marks of truth which are readily discovered.

These may be reduced to two principles,—the authority of him who propounds the thing, and the manner in which it is propounded. And these two ways of persuading are so powerful that they carry away almost all minds.

We may derive convincing arguments in matters of religion from the manner in which they are advanced. When we see, for example, in different ages of the church, and principally in the last, men who endeavour to propagate their opinions by bloodshed and the sword; when we see them arm themselves against the church by schism, against temporal powers by revolt; when we see people without the common commission, without miracles, without any external marks of piety, and with the plain marks rather of licentiousness, undertake to change the faith and discipline of the church in so criminal a manner, it is more than suffi-

cient to make reasonable men reject them, and to prevent the most ignorant from listening to them.

But in those things, the knowledge of which is not absolutely necessary, and which God has left more to the discernment of the reason of each one in particular, the authority and the manner are not so important, and they often lead many to form judgments contrary to the truth.

We do not undertake to give here the rules and the precise limits of the respect which is due to authority in human things, we simply indicate some gross faults which are committed in this matter.

We often regard only the number of the witnesses, without at all considering whether the number increases the probability of their having discovered the truth, which is, however, unreasonable; for, as an author of our time has wisely remarked, in difficult things, which each must discover for himself, it is more likely that a single person will discover the truth than that many will. Thus the following is not a valid inference: this opinion is held by the majority of philosophers; it is, therefore, the truest.

We are often persuaded, by certain qualities which have no connection with the truth, of the things which we examine. Thus there are a number of people who trust implicitly to those who are older, and who have had more experience, even in those things which do not depend on age or experience, but on the clearness of the mind.

Piety, wisdom, moderation, are without doubt the most estimable qualities in the world, and they ought to give great authority to those who possess them in those things which depend on piety or sincerity, and even on the knowledge of God, for it is most probable that God communicates more to those who serve him more purely; but there are a

multitude of things which depend only on human intelligence, human experience, and human penetration, and, in these things, those who have the superiority in intellect and in study, deserve to be relied on more than others. The contrary, however, often happens, and many reckon it best to follow, even in these things, the most devout men.

This arises, in part, from the fact that these advantages of mind are not so obvious as the external decorum which appears in pious persons, and in part, also, from the fact that men do not like to make these distinctions. Discrimination perplexes them; they will have all or nothing. If they trust to a man in one thing, they will trust to him in everything; if they do not in one, they will not in any; they love short, plain, and easy ways. But this disposition, though common, is nevertheless contrary to reason, which shows us that the same persons are not to be trusted to in anything, because they are not distinguished in anything; and that it is bad reasoning to conclude: he is a serious man, therefore he is intelligent and clever in everything.

VII.

It is true, indeed, that if any errors are pardonable, those into which we fall through our excessive deference to the opinion of good men are among the number. But there is a delusion much more absurd in itself, but which is nevertheless very common, that, namely, of believing that a man speaks the truth because he is a man of birth, of fortune, or high in office.

Not that any formally make these kinds of reasonings—he has a hundred thousand livres a year; therefore he possesses judgment: he is of high birth; therefore what he advances must be true: he is a poor man; therefore he

is wrong. Nevertheless, something of this kind passes through the minds of the majority, and unconsciously bears away their judgment.

Let the same thing be proposed by a man of quality, and by one of no distinction, and it will often be found that we approve of it in the mouth of the former, when we scarcely condescend to listen to it in that of the latter. Scripture designed to teach us this disposition of men, in that perfect representation which is given of it in the book of Ecclesiasticus.* "When a rich man speaketh, every one holdeth his tongue, and look, what he saith they extol it to the skies; but if the poor man speak, they say, 'What fellow is this?'" *(Dives locutus est, et omnes tacuerunt, et verbum illius usque ad nubes perducent; pauper locutus est, et dicunt, Quis est hic?)*

It is certain that complaisance and flattery have much to do with the approbation which is bestowed on the actions and words of people of quality; as also that they often gain this by a certain outward grace, and by a noble, free, and natural bearing, which is sometimes so distinctive that it is almost impossible for it to be imitated by those who are of low birth. It is certain, also, that there are many who approve of everything which is done and said by the great, through an inward abasement of soul, who bend under the weight of grandeur, and whose sight is not strong enough to bear its lustre; as, indeed, that the outward pomp which environs them always imposes a little, and makes some impression on the strongest minds.

This illusion springs from the corruption of the heart of man, who, having a strong passion for honours and pleasures,

---

Ecclesiasticus xiii. 23.

necessarily conceives a great affection for the means by which these honours and pleasures are obtained. The love which we have for all those things which are valued by the world, makes us judge those happy who possess them ; and, in thus judging them happy, we place them above ourselves, and regard them as eminent and exalted persons. This habit of regarding them with respect passes insensibly from their fortune to their mind. Men do not commonly do things by halves : we, therefore, give them minds as exalted as their rank ; we submit to their opinions ; and this is the reason of the credit which they commonly obtain in the affairs which they manage.

But this illusion is still stronger in the great themselves, when they have not laboured to correct the impression which their fortune naturally makes on their minds, than it is in their inferiors. Some derive from their estate and riches a reason for maintaining that their opinions ought to prevail over those who are beneath them. They cannot bear that those people whom they regard with contempt should pretend to have as much judgment and reason as themselves, and this makes them so impatient of the least contradiction. All this springs from the same source, that is, from the false ideas which they have of their grandeur, nobility, and wealth. Instead of considering them as things altogether foreign from their character, which do not prevent them at all from being perfectly equal to all the rest of men, both in mind and body, and which do not prevent their judgment even from being as weak and as liable to be deceived as that of all others, they, in some sort, incorporate with their very essence all these qualities of grand, noble, rich, master, lord, prince,—they exaggerate their idea of themselves with these

things, and never represent themselves to themselves without all their titles, their equipage, and their train.

They are accustomed from their infancy to consider themselves as of a different species from other men ; they never mingle in imagination with the mass of human kind ; they are, in their own eyes, always counts or dukes, and never simply men. Thus they shape to themselves a soul and judgment according to the measure of their fortune, and believe themselves as much above others in mind as they are above them in birth and fortune.

The folly of the human mind is such, that there is nothing which may not serve to aggrandise the idea which it has of itself. A beautiful horse, grand clothes, a long beard, make men consider themselves more clever ; and there are few who do not think more of themselves on horseback or in a coach than on foot. It is easy to convince everybody that there is nothing more ridiculous than these judgments, but it is very difficult to guard entirely against the secret impression which these outward things make upon the mind. All that we can do is to accustom ourselves as much as possible to give no influence at all to those qualities which cannot contribute towards finding the truth, and to give it even to those which do thus contribute only so far as they really contribute to this end. Age, knowledge, study, experience, mind, energy, memory, accuracy, labour, avail to find the truth of hidden things, and these qualities, therefore, deserve to be respected ; but it is always necessary to weigh with care, and then to make a comparison with the opposite reasons ; for from separate individual things we can conclude nothing with certainty, since there are very false opinions which have been sanctioned by men of great mental power, who possessed these qualities to a great extent.

VIII.

There is something still more deceptive in the mistakes which arise from the manner, for we are naturally led to believe that a man is in the right when he speaks with grace, with ease, with gravity, with moderation, and with gentleness; and, on the contrary, that a man is in the wrong when he speaks harshly, or manifests anything of passion, acrimony, or presumption, in his actions and words.

Nevertheless, if we judge of the essence of things by these outward and sensible appearances, we must be often deceived. For there are many people who utter follies gravely and modestly; and others, on the contrary, who, being naturally of a quick temper, or under the influence even of some passion, which appears in their countenance or their words, have nevertheless the truth on their side. There are some men of very moderate capacity, and very superficial, who, from having been nourished at court, where the art of pleasing is studied and practised better than anywhere else, have very agreeable manners, by means of which they render many false judgments acceptable; and there are others, on the contrary, who, having nothing outward to recommend them, have, nevertheless, a great and solid mind within. There are some who speak better than they think, and others who think better than they speak. Thus reason demands of those who are capable of it, that they judge not by these outward things, and hesitate not to yield to the truth, not only when it is proposed in ways that are offensive and disagreeable, but even when it is mingled with much of falsehood; for the same person may speak truly in one thing, and falsely in another; may be right in one thing, and wrong in another.

It is necessary, therefore, to consider each thing separately, that is to say, we must judge of the manner by the manner, and of the matter by the matter, and not of the matter by the manner, nor of the manner by the matter. A man does wrong to speak with anger, and he does right to speak the truth; and, on the contrary, another is right in speaking calmly and civilly, and he is wrong in advancing falsehoods.

But as it is reasonable to be on our guard against concluding that a thing is true or false, because it is proposed in such a way, it is right, also, that those who wish to persuade others of any truth which they have discovered, should study to clothe it in the garb most suitable for making it acceptable, and to avoid those revolting ways of stating it which only lead to its rejection.

They ought to remember that when we seek to move the minds of people, it is a small thing that we have right on our side; and it is a great evil to have only right, and not to have also that which is necessary for making it acceptable.

If they seriously honour the truth, they ought not to dishonour it by covering it with the marks of falsehood and deceit; and if they love it sincerely, they ought not to attach to it the hatred and aversion of men, by the offensive way in which they propound it. It is the most important, as well as the most useful precept of rhetoric, that it behoves us to govern the spirit as well as the words; for although it is a different thing to be wrong in the manner from being wrong in the matter, the faults, nevertheless, of the manner are often greater and more important than those of the matter.

In reality, all these fiery, presumptuous, bitter, obstinate, passionate manners, always spring from some disorder of the mind, which is often more serious than the defect of intelligence and of knowledge, which we reprehend in others. It is, indeed, always unjust to seek to persuade men in this way; for it is very right that we should lead them to the truth when we know it; but it is wrong to compel others to take as true everything that we believe, and to defer to our authority alone. We do this, however, when we propose the truth in this offensive manner. For the way of speaking generally enters into the mind before the reasons, since the mind is more prompt to notice the manner of the speaker than it is to comprehend the solidity of his proofs, which are often, indeed, not comprehended at all. Now the manner of the discourse being thus separated from the proofs, marks only the authority which he who speaks arrogates to himself; so that if he is bitter and imperious, he necessarily revolts the minds of others, since he appears to wish to gain, by authority, and by a kind of tyranny, that which ought only to be obtained by persuasion and reason.

This injustice is still greater when we employ these offensive ways in combating common and received opinions; for the judgment of an individual may indeed be preferred to that of many when it is more correct, but an individual ought never to maintain that his authority should prevail against that of all others.

Thus, not only modesty and prudence, but justice itself, obliges us to assume a modest air when we combat common opinions or established authority, otherwise we cannot escape the injustice of opposing the authority of an individual to an authority either public, or greater and more widely established than our own. We cannot exercise too much modera-

tion when we seek to disturb the position of a received opinion or of an ancient faith. This is so true, that St. Augustine extended it even to religious truths, having given this excellent rule to all those who have to instruct others :—

"Observe," says he, "in what way the wise and religious catholics taught that which they had to communicate to others. If they were things common and authorized, they propounded them in a manner full of assurance, and free from every trace of doubt by being accompanied with the greatest possible gentleness ; but if they were extraordinary things, although they themselves very clearly recognized their truth, they still proposed them rather as *doubts* and as *questions* to be examined, than as dogmas and fixed decisions, in order to accommodate themselves in this to the weakness of those who heard them." And so if a truth be so high that it is above the strength of those to whom it is spoken, they prefer rather to keep it back for a while, in order to give them time for growth, and for becoming capable of receiving it, instead of making it known to them that state of weakness in which it would have overwhelmed them.

SIR WILLIAM HAMILTON

ON

MODIFIED LOGIC.

LECTURES ON LOGIC.

LECTURE I.—MODIFIED LOGIC.

PART I.—MODIFIED STOICHEIOLOGY.

SECTION I.—DOCTRINE OF TRUTH AND ERROR.

TRUTH—ITS CHARACTER AND KINDS.

Modified Logic,—its object

HAVING now terminated the Doctrine of Pure or Abstract Logic, we proceed to that of Modified or Concrete Logic. In entering on this subject, I have to recall to your memory what has formerly been stated in regard to the object which Modified Logic proposes for consideration. Pure Logic takes into account only the necessary conditions of thought, as founded on the nature of the thinking process itself. Modified Logic, on the contrary, considers the conditions to which thought is subject, arising from the empirical circumstances, external and internal, under which exclusively it is the will of our Creator that man should manifest his faculty of thinking. Pure Logic is thus exclusively conversant with the form; Modified Logic is, likewise, occupied with the matter, of thought. And as their objects are different,

so, likewise, must be their ends. The end of Pure Logic is formal truth,—the harmony of thought with thought; the end of Modified Logic is the harmony of thought with existence. Of these ends, that which Pure Logic proposes is less ambitious, but it is fully and certainly accomplished; the end which Modified Logic proposes is higher, but it is far less perfectly attained. The problems which Modified Logic has to solve may be reduced to three: 1°, What is truth and its contradictory opposite,—Error? 2°, What are the Causes of Error, and the Impediments to Truth, by which man is beset in the employment of his faculties, and what are the Means of their Removal? And, 3°, What are the Subsidiaries by which Human Thought may be strengthened and guided in the exercise of its functions?

Its problems,—reduced to three.

From this statement it is evident that Concrete Logic might, like Pure Logic, have been divided into a Stoicheiology and a Methodology,—the former comprising the first two heads,—the latter the third. For if to Modified Stoicheiology we refer the consideration of the nature of concrete truth and error, and of the conditions of a merely not erroneous employment of thought,—this will be exausted in the First and Second Chapters; whereas, if we refer to Methodology a consideration of the means of employing thought not merely without error, but with a certain positive perfection,—this is what the Third Chapter professes to expound.

And distributed between its Stoicheiology and its Methodology.

I commence the First Chapter, which proposes to answer the question,—What is Truth? with its correlatives,—by the dictation of the following paragraphs:

Par. I. Truth and Certainty,—what.

¶ I. The end which all our scientific efforts are exerted to accomplish, is *Truth* and *Certainty*. Truth is the correspondence or agreement of a cognition with its object; its Criterion is the necessity determined by the laws which govern our faculties of knowledge; and Certainty is the consciousness of this necessity. Certainty, or the conscious necessity of knowledge, absolutely excludes the admission of any opposite supposition. Where such appears admissible, doubt and uncertainty arise. If we consider truth by relation to the degree and kind of Certainty, we have to distinguish *Knowledge*, *Belief*, and *Opinion*. Knowledge and Belief differ not only in degree, but in kind. Knowledge is a certainty founded upon insight; Belief is a certainty founded upon feeling. The one is perspicuous and objective; the other is obscure and subjective. Each, however, supposes the other; and an assurance is said to be a knowledge or a belief, according as the one element or the other preponderates. Opinion is the admission of something as true, where, however, neither insight nor feeling is so intense as to necessitate a perfect certainty. What prevents the admission of a proposition as certain is called *Doubt*. The approximation of the imperfect certainty of opinion to the perfect certainty of knowledge or belief is called *Probability*.

If we consider Truth with reference to Knowledge, and to the way in which this knowledge arises, we must distinguish *Empirical* or *a posteriori*, from *Pure* or *a priori Truth*. The former has reference to cognitions which have their source in the presentations of

Perception, External and Internal, and which obtain their form by the elaboration of the Understanding or faculty of Relations (διάνοια). The latter is contained in the necessary and universal cognitions afforded by the Regulative Faculty—Intellect Proper—or Common Sense (νοῦς).

Explication.

This paragraph, after stating that Truth and Certainty constitute the end of all our endeavors after knowledge, for only in the attainment of truth and certainty can we possibly attain to knowledge or science;—I say, after the statement of this manifest proposition,—it proceeds to define what is meant by the two terms *Truth* and *Certainty;* and, to commence with the former,—Truth is defined, the correspondence or agreement of a cognition or cofinitive act of thought with its object.

Truth,—what.

The question—What is truth? is an old and celebrated problem. It was proposed by the Roman Governor—by Pontius Pilate—to our Saviour; and it is a question which still recurs, and is still keenly agitated in the most recent schools of Philosophy. In one respect all are nearly agreed in regard to the definition of the term, for all admit that by truth is understood a harmony,—an agreement, a correspondence between our thought and that which we think about. This definition of truth we owe to the schoolmen. "*Veritas intellectus,*" says Acquinas, "*est adœquatio intellectus et rei, secundum quod intellectus dicit esse, quod est, vel non esse, quod non est.*" From the schoolmen, this definition has been handed down to modern philosophers, by whom it is currently employed, without, in general, a suspicion of its origin. It is not, therefore, in regard to the meaning of the term *truth*, that there is any

Definition of the term.

difference of opinion among philosophers. The questions which have provoked discussion, and which remain, as heretofore, without a definitive solution, are not whether truth be the harmony of thought and reality, but whether this harmony, or truth, be attainable, and whether we possess any criterion by which we can be assured of its attainment. Considering, however, at present only the meaning of the term, philosophers have divided the Truth (or the harmony of thought and its object) into different species, to which they have given diverse names; but they are at one neither in the division nor in the nomenclature.

Questions in debate regarding Truth.

It is plain that for man there can only be conceived two kinds of truth, because there are for human thought only two species of object. For that about which we think must either be a thought, or something which a thought contains. On this is founded the distinction of Formal Knowledge and Real Knowledge,—of Formal Truth and Real Truth. Of these in their order:

For man only two kinds of Truth,—Formal and Real.

I. In regard to the former, a thought abstracted from what it contains, that is, from its matter or what it is conversant about, is the more form of thought. The knowledge of the form of thought is a formal knowledge, and the harmony of thought with the form of thought is, consequently, Formal Truth. Now Formal Knowledge is of two kinds; for it regards either the conditions of the Elaborative Faculty,—the Faculty of Thought Proper,—or the conditions of our Presentations or Representations of external things, that is, the intuitions of Space and Time. The former of these sciences is Pure

I. Formal Truth.

Formal Truth of two kinds,—Logical and Mathematical.

Logic—the science which considers the laws to which the Understanding is astricted in its elaborative operations, without enquiring what is the object,—what is the matter, to which these operations are applied. The latter of these sciences is Mathematics, or the science of Quantity, which considers the relations of Time and Space, without enquiring whether there be any actual reality in space or time. Formal truth will, therefore, be of two kinds,—Logical and Mathematical. Logical truth is the harmony or agreement of our thoughts with themselves as thoughts, in other words, the correspondence of thought with the universal laws of thinking. These laws are the object of Pure or General Logic, and in these it places the criterion of truth. This criterion is, however, only the negative condition—only the *conditio sine qua non*, of truth. Logical truth is supposed in supposing the possibility of thought; for all thought presents a combination, the elements of which are repugnant or congruent, but which cannot be repugnant and congruent at the same time. Logic might be true, although we possessed no truth beyond its fundamental laws; although we knew nothing of any real existence beyond the formal hypothesis of its possibility.

Logical Truth.

But were the Laws of Logic purely subjective, that is, were they true only for our thought alone, and without any objective validity, all human sciences (and Mathematics among the rest) would be purely subjective likewise; for we are cognizant of objects only under the forms and rules of which Logic is the scientific development. If the true character of objective validity be universality, the Laws of Logic are really of that character, for these laws constrain

us, by their own authority, to regard them as the universal laws not only of human thought, but of universal reason.

Mathematical Truth.

The case is the same with the other formal science, the science of Quantity, or Mathematics. Without inquiring into the reality of existences, and without borrowing from, or attributing to, them anything, Arithmetic, the science of Discrete Quantity, creates its numbers, and Geometry, the science of Continuous Quantity, creates its figures; and both operate upon these their objects in absolute independence of all external actuality. The two mathematical sciences are dependent for their several objects only on the notion of time and the notion of space,—notions under which alone matter can be conceived as possible, for all matter supposes space, and all matter is moved in space and time. But to the notions of space and time the existence or non-existence of matter is indifferent; indifferent, consequently, to Geometry and Arithmetic, so long at least as they remain in the lofty regions of pure speculation, and do not descend to the practical application of their principles. If matter had no existence, nay, if space and time existed only in our minds, mathematics would still be true; but their truth would be of a purely formal and ideal character,—would furnish us with no knowledge of objective realities.

So much for Formal Truth, under its two species of Logical and Mathematical.

II. Real Truth.

Real and Formal Sciences.

The other genus of truth—(the end which the Real Sciences propose)—is the harmony between a thought and its matter. The Real Sciences are those which have a determinate reality for their object, and which are conversant about existences other than the forms of thought.

The Formal Sciences have a superior certainty to the real; for they are simply ideal combinations, and they construct their objects without inquiring about their objective reality. The real sciences are sciences of fact, for the point from which they depart is always a fact,—always a presentation. Some of these rest on the presentations of Self-consciousness, or the facts of mind; others on the presentations of Sensitive Perception, or the facts of nature. The former are the Mental Sciences, the latter the Material. The facts of mind are given partly as contingent, partly as necessary; the latter—the necessary facts—are universal virtually and in themselves; the former—the contingent facts—only obtain a fictitious universality by a process of generalization. The facts of nature, however necessary in themselves, are given to us only as contingent and isolated phænomena; they have, therefore, only that conditional, that empirical, generality, which we bestow on them by classification.

Under the Real Sciences are included the Mental and Material.

Real truth is, therefore, the correspondence of our thoughts with the existences which constitute their objects. But here a difficulty arises:—How can we know that there is, that there can be, such a correspondence? All that we know of the objects is through the presentations of our faculties; but whether these present the objects as they are in themselves, we can never ascertain, for to do this it would be requisite to go out of ourselves,—out of our faculties,—to obtain a knowledge of the objects by other faculties, and thus to compare our old presentations with our new. But all this, even were the supposition possible, would be incompetent to

How can we know that there is a correspondence between our thought and its object?

afford us the certainty required. For were it possible to leave our old, and to obtain a new, set of faculties, by which to test the old, still the veracity of these new faculties would be equally obnoxious to doubt as the veracity of the old. For what guarantee could we obtain for the credibility in the one case, which we do not already possess in the other? The new faculties could only assert their own truth; but this is done by the old; and it is impossible to imagine any presentations of the non-ego by any finite intelligence, to which a doubt might not be raised; whether these presentations were not merely subjective modifications of the conscious ego itself. All that could be said in answer to such a doubt is, that if such were true, our whole nature is a lie,—a supposition which is not, without the strongest evidence, to be admitted; and the argument is as competent against the sceptic in our present condition, as it would be were we endowed with any other conceivable form of Acquisitive and Cognitive Faculties. But I am here trenching on what ought to be reserved for an explanation of the Criterion of Truth.

Real Truth,—its subdivisions.

Such, as it appears to me, is the only rational division of Truth according to the different character of the objects to which thought is relative, —into Formal and into Real Truth. Formal Truth, as we have seen, is subdivided into Logical and into Mathematical. Real Truth might likewise be subdivided, were this requisite, into various species. For example, Metaphysical Truth might denote the harmony of thought with the necessary facts of mind; Psychological Truth, the harmony of thought with the contingent facts of mind; and Physical Truth, the harmony of thought with the phænomena of external experience.

Metaphysical.
Psychological.
Physical.

Various applications of the term *Truth*.

It now remains to say a word in regard to the confusion which has been introduced into this subject, by the groundless distinctions and contradictions of philosophers. Some have absurdly given the name of *truth* to the mere reality of existence, altogether abstracted from any conception or judgment relative to it, in any intelligence, human or divine. In this sense *physical truth* has been used to denote the actual existence of a thing. Some have given the name of *metaphysical truth* to the congruence of the thing with its idea in the mind of the Creator. Others again have bestowed the name of *metaphysical truth* on the mere logical possibility of being thought; while they have denominated by *logical truth* the metaphysical or physical correspondence of thought with its objects. Finally, the term *moral* or *ethical truth* has been given to veracity, or the correspondence of thought with its expression. In this last case, truth is not, as in the others, employed in relation to thought and its object, but to thought and its enouncement. So much for the notion, and the principal distinctions of Truth.

The Criterion of Truth.

But, returning to the paragraph; I take the next clause, which is,—"The Criterion of truth is the necessity determined by the laws which govern our faculties of knowledge; and the consciousness of this necessity is certainty." That the necessity of a cognition, that is, the impossibility of thinking it other than as it is presented,—that this necessity, as founded on the laws of thought, is the criterion of truth, is shown by the circumstance that where such necessity is found, all doubt in regard to the correspondence of the cognitive thought and its object must vanish; for to doubt

whether what we necessarily think in a certain manner, actually exists as we conceive it, is nothing less than an endeavor to think the necessary as the not necessary or the impossible, which is contradictory.

What has just been said also illustrates the truth of the next sentence of the paragraph, viz.,—"Certainty or the conscious necessity of a cognition absolutely excludes the admission of any opposite supposition. When such is found to be admissible, doubt and uncertainty arise." This sentence requiring no explanation, I proceed to the next, viz., —"If we consider truth by the relation to the degree and kind of Certainty, we have to distinguish Knowledge, Belief, and Opinion. Knowledge and Belief differ not only in degree but in kind. Knowledge is a certainty founded on intuition. Belief is a certainty founded upon feeling. The one is perspicuous and objective, the other is obscure and subjective. Each, however, supposes the other, and an assurance is said to be a knowledge or a belief, according as the one element or the other preponderates."

In reference to this passage, it is necessary to say something in regard to the difference of Knowledge and Belief. In common language the word *Belief* is often used to denote an inferior degree of certainty. We may, however, be equally certain of what we believe as of what we know, and it has, not without ground, been maintained by many philosophers, both in ancient and in modern times, that the certainty of all knowledge is, in its ultimate analysis, resolved into a certainty of belief. "All things," says Luther, "stand in a belief, in a faith, which he can neither see nor comprehend. The

Knowledge and Belief—their difference.

That the certainty of all knowledge is ultimately resolvable into a certainty of Belief, maintained by Luther.

man who would make these visible, manifest, and comprehensible, has vexation and heart-grief for his reward. May the Lord increase Belief in you and in others." But you may perhaps think that the saying of Luther is to be taken theologically, and that, philosophically considered, all belief ought to be founded on knowledge, not all knowledge in belief. But the same doctrine is held even by those philosophers who are the least disposed to mysticism or blind faith. Among these Aristotle stands distinguished. He defines science, strictly so called, or the knowledge of indubitable truths, merely by the intensity of our conviction or subjective assurance; and on a primary and incomprehensible belief he hangs the whole chain of our comprehensible or immediate knowledge. The doctrine which has been called *The Philosophy of Common Sense*, is the doctrine which founds all our knowledge on belief; and, though this has not been signalized, the doctrine of Common Sense is perhaps better stated by the Stagirite than by any succeeding thinker. "What," he says, "appears to all men, that we affirm to be, and he who rejects this belief (πίστις) will assuredly advance nothing better worthy of credit." This passage is from his *Nicomachean Ethics*. But, in his Physical Treatises, he founds in belief the knowledge we have of the reality of motion, and by this, as a source of knowledge paramount to the Understanding, he supersedes the contradictions which are involved in our conception of motion, and which had so acutely been evolved by the Eleatic Zeno, in order to show that motion was impossible. In like manner, in his Logical Treatises, Aristotle shows that the primary or ultimate principles of knowledge must be incomprehensible; for if comprehensible, they must be comprehended in some higher

Aristotle.

notion, and this again, if not itself incomprehensible, must be again comprehended in a still higher, and so on in a progress *ad infinitum*, which is absurd. But what is given as an ultimate and incomprehensible principle of knowledge, is given as a fact, the existence of which we must admit, but the reasons of whose existence we cannot know,—we cannot understand. But such an admission, as it is not a knowledge, must be a belief; and thus it is that, according to Aristotle, all our knowledge is in its root a blind, a passive faith, in other words, a feeling. The same doctrine was subsequently held by many of the acutest thinkers of ancient times, more especially among the Platonists; and of these Proclus is perhaps the philosopher in whose works the doctrine is turned to the best account. In modern times we may trace it in silent operation, though not explicitly proclaimed, or placed as the foundation of a system. It is found spontaneously recognized even by those who might be supposed the least likely to acknowledge it without compulsion. Hume, for example, against whose philosophy the doctrine of Common Sense was systematically arrayed, himself pointed out the weapons by which his adversaries subsequently assailed his scepticism; for he himself was possessed of too much philosophical acuteness not to perceive that the root of knowledge is belief. Thus, in his *Inquiry*, he says,—"It seems evident that men are carried by a natural instinct or prepossession to repose faith in their senses: and that, without any reasoning, or even almost before the use of reason, we always suppose an external universe which depends not on our perception, but would exist though we and every sensible creature were absent or annihilated. Even the animal

The Platonists. Proclus.

Hume.

creation are governed by a like opinion, and preserve this belief,—the belief of external objects, in all their thoughts, designs, and actions. . . . . This very table which we see white, and which we feel hard, is believed to exist independent of our perception, and to be something external to our mind which perceives it."

The manifestation of Belief involves Knowledge.

But, on the other hand, the manifestation of this belief necessarily involves knowledge; for we cannot believe without some consciousness or knowledge of the belief, and, consequently, without some consciousnesss or knowledge of the object of the belief. Now the immediate consciousness or knowledge of an object is called an *intuition*,—an *insight*. It is thus impossible to separate belief and knowledge,—feeling and intuition. They each suppose the other.

Intuition,—what.

The question as to the relation of Belief and Knowledge properly metaphysical.

The consideration, however, of the relation of Belief and Knowledge does not properly belong to Logic, except in so far as it is necessary to explain the nature of Truth and Error. It is altogether a metaphysical discussion; and one of the most difficult problems of which Metaphysics attempts the solution.

The remainder of the paragraph contains the statement of certain distinctions and the definition of certain terms, which it was necessary to signalize, but which do not require any commentary for their illustration. The only part that might have required an explanation is the distinction of Truth into Pure, or *a priori*, and into Empirical, or *a posteriori*. The explanation of this division has been already given more than once, but the following may now be added.

Pure and Empirical Truth.

Experience presents to us only individual objects, and as these individual objects might or might not have come within our sphere of observation, our whole knowledge of and from these objects might or might not exist;—it is merely accidental or contingent. But as our knowledge of individual objects affords the possibility, as supplying the whole contents, of our generalized or abstracted notions, our generalized or abstracted notions are, consequently, not more necessary to thought, than the particular observations out of which they are constructed. For example, every horse I have seen I might not have seen; and I feel no more necessity to think the reality of a horse than the reality of a hippogriff; I can, therefore, easily annihilate in thought the existence of the whole species. I can suppose it not to be,—not to have been. The case is the same with every other notion which is mediately or immediately the datum of observation. We can think away each and every part of the knowledge we have derived from experience; our whole empirical knowledge is, therefore, a merely accidental possession of the mind.

But there are notions in the mind of a very different character,—notions which we cannot but think, if we think at all. These, therefore, are notions necessary to the mind; and, as necessary, they cannot be the product of experience. For example, I perceive something to begin to be. I feel no necessity to think that this thing must be at all, but thinking it existent, I cannot but think that it has a cause. The notion, or rather the judgment, of Cause and Effect, is, therefore, necessary to the mind. If so, it cannot be derived from experience.

LECTURE II.—MODIFIED STOICHEIOLOGY.

SECTION I.—DOCTRINE OF TRUTH AND ERROR.

SECTION II.—ERROR,—ITS CAUSES AND REMEDIES.

A.—GENERAL CIRCUMSTANCES—SOCIETY.

I now proceed to the consideration of the opposite of Truth,—Error, and, on this subject, give you the following paragraph:

¶ II. Error is opposed to Truth; and Error arises, 1°, From the commutation of what is Subjective and what is Objective in thought; 2°, From the Contradiction of a supposed knowledge with its Laws; or, 3°, From a want of Adequate Activity in our Cognitive Faculties.

Par. II. Error,—its character and sources.

Error is to be discriminated from *Ignorance* and from *Illusion;* these, however, along with Arbitrary Assumption, afford the most frequent occasions of error.

This paragraph consists of two parts, and these I shall successively consider. The first is: "Error is opposed to truth; and Error arises,—1°, From the commutation of what is subjective with what is objective in thought; 2°, From the contradiction of a

Explication.

supposed knowledge with its laws; or, 3°, From a want of adequate activity in our cognitive faculties."

Error,—what.

"In the first place, we have seen that Truth is the agreement of a thought with its object. Now, as Error is the opposite of truth,—Error must necessarily consist in a want of this agreement. In the second place, it has been shown that the criterion or standard of truth is the necessity founded on the laws of our cognitive faculties; and from this it follows that the essential character of error must be, either that it is not founded on these laws, or that it is repugnant to them. But these two alternatives may be viewed as only one; for inasmuch as, in the former case, the judgment remains undecided, and can make no pretence to certainty, it may be thrown out of account no less than in the latter, where, as positively contradictory of the laws of knowledge, it is necessarily false. Of these statements the first, that is, the non-agreement of a notion with its object, is error viewed on its material side; and as a notion is the common product,—the joint result afforded by the reciprocal action of object and subject, it is evident that whatever the notion contains not correspondent to the object, must be a contribution by the thinking subject alone, and we are thus warranted in saying that Material Error consists in the commuting of what is subjective with what is objective in thought; in other words, in mistaking an ideal illusion for a real representation. The second of these statements, that is, the incongruence of the supposed cognition with the laws of knowledge, is error viewed on its formal side. Now here the question at once presents itself,—How can an act of

As Material.

As Formal.

cognition contradict its own laws? The answer is that it cannot; and error, when more closely scrutinized, is found not so much to consist in the contradictory activity of our cognitive faculties as in their want of activity. And this may be in consequence of one or other of two causes. For it may arise from some other mental power,—the will, for example, superseding,—taking the place of, the defective cognition, or, by its intenser force, turning it aside and leading it to a false result; or it may arise from some want of relative perfection in the object, so that the cognitive faculty is not determined by it to the requisite degree of action.

Arises from the want of adequate activity of the Cognitive Faculties.

"What is actually thought, cannot but be correctly thought. Error first commences when thinking is remitted, and can in fact only gain admission in virtue of the truth which it contains;—every error is a perverted truth. Hence Descartes is justified in the establishment of the principle,—that we would never admit the false for the true, if we would only give assent to what we clearly and distinctly apprehend. '*Nihil nos unquam falsum pro vero admissuros, si tantum iis assensum præbeamus, quæ clare et distincte percipimus.*'" In this view the saying of the Roman poet—

"*Nam neque decipitur ratio, nec decipit unquam,*"

—is no longer a paradox; for the condition of error is not the activity of intelligence, but its inactivity.

So much for the first part of the paragraph. The second is—"Error is to be discriminated from Ignorance and from Illusion, which, however, along with Arbitrary Assumption, afford the usual occasions of Error."

Error discriminated from Ignorance and Illusion.

"Ignorance is a mere negation,—a mere not-knowledge; whereas in error there lies a positive pretence to knowledge. Hence a representation, be it imperfect, be it even without any correspondent objective reality, is not in itself an error. The imagination of a hippogriff is not in itself false; the Orlando Furioso is not a tissue of errors. Error only arises when we attribute to the creations of our minds some real object, by an assertory judgment; we do not err and deceive either ourselves or others, when we hold and enounce a subjective or problematic supposition only for what it is. Ignorance,—not knowledge,—however, leads to error, when we either regard the unknown as non-existent, or when we falsely fill it up. The latter is, however, as much the result of Will, of arbitrary assumption, as of ignorance; and, frequently, it is the result of both together. In general, the will has no inconsiderable share in the activity by which knowledge is realized. The will has not immediately an influence on our judgment, but mediately it has. Attention is an act of volition, and attention furnishes to the understanding the elements of its decision. The will determines whether we shall carry on our investigations, or break them off, content with the first apparent probability; and whether we shall apply our observations to all, or, only partially, to certain, momenta of determination.

Ignorance.

"The occasions of Error which lie in those qualities of Presentation, Representation, and Thought arising from the conditions and influences of the thinking subject itself, are called *Illusions*. But the existence of illusion does not necessarily imply the existence of error. Illusion becomes error only when we attribute to it objective truth; whereas illusion is no error when we

Illusion.

regard the fallacious appearance as a mere subjective affection. In the jaundice, we see everything tinged with yellow, in consequence of the suffusion of the eye with bile. In this case, the yellow vision is illusion; and it would become error, were we to suppose that the objects we perceive were really so colored. All the powers which cooperate to the formation of our judgments may become the sources of illusion, and, consequently, the occasions of error. The Senses, the Presentative Faculties, External and Internal, the Representative, the Retentive, the Reproductive, and the Elaborative Faculties, are immediate, the Feelings and the Desires are mediate, sources of illusion. To these must be added the Faculty of Signs, in all its actual manifestations in language. Hence we speak of sensible, psychological, moral, and symbolical, illusion. In all these relations the causes of illusion are partly general, partly particular; and though they proximately manifest themselves in some one or other of these forms, they may ultimately be found contained in the circumstances by which the mental character of the individual is conformed. Taking, therefore, a general view of all the possible Sources of Error, I think they may be reduced to the following classes, which, as they constitute the heads and determine the order of the ensuing discussion, I shall comprise in the following paragraph, with which commences the consideration of the Second Chapter of Modified Logic. Before, however, proceeding to consider these several classes in their order, I may observe that Bacon is the first philosopher who attempted a systematic enumeration of the various sources of error; and his quaint classification of these, under the significant name of *idols*, into the

Its sources.

Bacon's classification of the sources of error.

four genera of Idols of the Tribe (*idola tribus*), Idols of the Den (*idola specus*), Idols of the Forum (*idola fori*), which may mean either the market-place, the bar, or the place of public assembly, and Idols of the Theatre (*idola theatri*), he thus briefly characterizes.

¶ III. The Causes and Occasions of Error are comprehended in one or other of the four following classes. For they are found either, 1°, In the General Circumstances which modify the intellectual character of the individual; or, 2°, In the Constitution, Habits, and Reciprocal Relations of his powers of Cognition, Feeling, and Desire; or, 3°, In the Language which he employs, as an Instrument of Thought and a Medium of Communication: or, 4°, In the nature of the Objects themselves, about which his knowledge is conversant.

Par. III. Error,—its sources.

¶ IV. Under the General Circumstances which modify the character of the individual are comprehended, 1°, The particular degree of Cultivation to which his nation has attained; for its rudeness, the partiality of its civilization, and its over-refinement are all manifold occasions of error; and this cultivation is expressed not merely in the state of the arts and sciences, but in the degree of its religious, political, and social advancement; 2°, The Stricter Associations, in so far as these tend to limit the freedom of thought, and to give it a one-sided direction; such are Schools, Sects, Orders, Exclusive Societies, Corporations, Castes, etc.

Par. IV. I. General Circumstances which modify the character of the individual.

In the commencement of the Course, I had occasion to

allude to the tendency there is in man to assimilate in opinions and habits of thought to those with whom he lives. Man is by nature, not merely by accidental necessity, a social being. For only in society does he find the conditions which his different faculties require for their due development and application. But society, in all its forms and degrees, from a family to a State, is only possible under the condition of a certain harmony of sentiment among its members; and as man is by nature destined to a social existence, he is by nature determined to that analogy of thought and feeling which society supposes, and out of which society springs. There is thus in every association, great and small, a certain gravitation of opinions towards a common centre. As in our natural body every part has a necessary sympathy with every other, and all together form, by their harmonious conspiration, a healthy whole; so, in the social body, there is always a strong predisposition in each of its members to act and think in unison with the rest. This universal sympathy or fellow-feeling is the principle of the different spirit dominant in different ages, countries, ranks, sexes, and periods of life. It is the cause why fashions, why political and religious enthusiasm, why moral example either for good or evil, spread so rapidly and exert so powerful an influence. As men are naturally prone to imitate others, they, consequently, regard as important or insignificant, as honorable or disgraceful, as true or false, as good or bad, what those around them consider in the same light.

Explication. Man by nature social, and influenced by the opinions of his fellows.

Of the various testimonies I formerly quoted, of the strong assimilating influence of man on man, and of the power of custom, to make that appear true, natural, and necessary,

Pascal quoted on the power of custom.

which in reality is false, unnatural, and only accidentally suitable, I shall only adduce that of Pascal. "In the just and the unjust," says he, "we find hardly anything which does not change its character in changing its climate. Three degrees of an elevation of the pole reverses the whole of jurisprudence. A meridian is decisive of truth, and a few years, of possession. Fundamental laws change. Right has its epochs. A pleasant justice which a river or a mountain limits! Truth on this side the Pyrenees, error on the other!" It is the remark of an ingenious philosopher, "that if we take a survey of the universe, all nations will be found admiring only the reflection of their own qualities, and contemning in others whatever is contrary to what they are accustomed to meet with among themselves. Here is the Englishman accusing the French of frivolity; and here the Frenchman reproaching the Englishman with selfishness and brutality. Here is the Arab persuaded of the infallibility of his Caliph, and deriding the Tartar who believes in the immortality of the Grand Lama. In every nation we find the same congratulation of their own wisdom, and the same contempt of that of their neighbors.

"Were there a sage sent down to earth from heaven, who regulated his conduct by the dictates of pure reason alone, this sage would be universally regarded as a fool. He would be, as Socrates says, like a physician accused by the pastry-cooks, before a tribunal of children, of prohibiting the eating of tarts and cheese-cakes; a crime undoubtedly of the highest magnitude in the eyes of his judges. In vain would this sage support his opinions by the clearest arguments,—the most irrefragable demonstrations; the whole world would be for him like the nation of hunch-

backs, among whom, as the Indian fabulists relate, there once upon a time appeared a god, young, beautiful, and of consummate symmetry. This god, they add, entered the capital; he was there forthwith surrounded by a crowd of natives; his figure appeared to them extraordinary; laughter, hooting, and taunts manifested their astonishment, and they were about to carry their outrages still further, had not one of the inhabitants (who had undoubtedly seen other men), in order to snatch him from the danger, suddenly cried out—'My friends! my friends! What are we going to do? Let us not insult this miserable monstrosity. If heaven has bestowed on us the general gift of beauty,—if it has adorned our backs with a mount of flesh, let us with pious gratitude repair to the temple and render our acknowledgement to the immortal gods.'" This fable is the history of human vanity. Every nation admires its own defects, and contemns the opposite qualities in its neighbors. To succeed in a country, one must be a bearer of the national hump of the people among whom he sojourns.

The art of doubting well difficult to teach and to learn.

There are few philosophers who undertake to make their countrymen aware of the ridiculous figure they cut in the eye of reason; and still fewer the nations who are able to profit by the advice. All are so punctiliously attached to the interests of their vanity, that none obtain in any country the name of wise, except those who are fools of the common folly. There is no opinion too absurd not to find nations ready to believe it, and individuals prompt to be its executioners or its martyrs. Hence it is that the philosopher declared, that if he held all truths shut up within his hand, he would take especial care not to show

them to his fellow-men. In fact, if the discovery of a single truth dragged Galileo to the prison, to what punishment would he not be doomed who should discover all? Among those who now ridicule the folly of the human intellect, and are indignant at the persecution of Galileo, there are few who would not, in the age of that philosopher, have clamored for his death. They would then have been imbued with different opinions; and opinions not more passively adopted than those which they at present vaunt as liberal and enlightened. To learn to doubt of our opinions, it is sufficient to examine the powers of the human intellect, to survey the circumstances by which it is affected, and to study the history of human follies. Yet in modern Europe six centuries elapsed from the foundation of Universities until the appearance of that extraordinary man,—I mean Descartes,—whom his age first persecuted, and then almost worshipped as a demi-god, for initiating men in the art of doubting,—of doubting well,—a lesson at which, however, both their skepticism and credulity show that, after two centuries, they are still but awkward scholars. Socrates was wont to say,—"All that I know is that I know nothing." In our age it would seem that men know everything except what Socrates knew. Our errors would not be so frequent were we less ignorant; and our ignorance more curable, did we not believe ourselves to be all-wise.

Thus it is that the influence of Society, both in its general form of a State or Nation, and in its particular forms of Schools, Sects, etc., determines a multitude of opinions in its members, which, as they are passively received, so they are often altogether erroneous.

Among the more general and influential of these there are two, which, though apparently contrary, are, however, both, in reality, founded on the same incapacity of independent thought, —on the same influence of example—I mean the excessive admiration of the Old, and the excessive admiration of the New. The former of these prejudices—under which may be reduced the prejudice in favor of Authority,—was at one time prevalent to an extent of which it is difficult for us to form a conception. This prejudice is prepared by the very education not only which we do, but which we all must receive. The child necessarily learns everything at first on credit,—he believes upon authority. But when the rule of authority is once established, the habit of passive acquiescence and belief is formed, and, once formed, it is not again always easily thrown off. When the child has grown up to an age in which he might employ his own reason, he has acquired a large stock of ideas; but who can calculate the number of errors which this stock contains? and by what means is he able to discriminate the true from the false? His mind has been formed to obedience and uninquiry; he possesses no criterion by which to judge; it is painful to suspect what has been long venerated, and it is felt even as a kind of personal mutilation to tear up what has become irradicated in his intellectual and moral being. *Ponere difficile est quæ placuere diu.* The adult does not, therefore, often judge for himself more than the child; and the tyranny of authority and foregone opinion continues to exert a sway during the whole course of his life. In our infancy and childhood the credit accorded to our parents and instructors is implicit;

Two general forms of the influence of example.

1. Prejudice in favor of the Old.

Prepared by Education.

and if what we have learned from them be confirmed by what we hear from others, the opinions thus recommended become at length stamped in almost indelible characters upon the mind. This is the cause why men so rarely abandon the opinions which vulgarly pass current; and why what comes as new is by so many, for its very novelty, rejected as false. And hence it is, as already noticed, that truth is as it were geographically and politically distributed; what is truth on one side of a boundary being error and absurdity on the other. What has now been said of the influence of society at large, is true also of the lesser societies which it contains, all of which impose with a stronger or feebler, a wider or more contracted, authority, certain received opinions upon the faith of the members. Hence it is that whatever has once obtained a recognition in any society, large or small, is not rejected when the reasons on which it was originally admitted have been proved erroneous. It continues, even for the reason that it is old and has been accepted, to be accepted still; and the title which was originally defective, becomes valid by continuance and prescription.

2. Prejudice in favor of the New.

But opposed to this cause of error, from the prejudice in favor of the Old, there is the other, directly the reverse,—the prejudice in favor of the New. This prejudice may be, in part at least, the result of sympathy and fellow-feeling. This is the cause why new opinions, however erroneous, if they once obtain a certain number of converts, often spread with a rapidity and to an extent, which, after their futility has been ultimately shown, can only be explained on the principle of a kind of intellectual contagion. But the principal cause of the prejudice in favor of novelty lies in the Passions,

and the consideration of these does not belong to the class of causes with which we are at present occupied.

Prejudice of Learned Authority.

Connected with and composed of both these prejudices,—that in favor of the old and that in favor of the new,—there is the prejudice of Learned Authority; for this is usually associated with the prejudices of Schools and Sects. As often as men have appeared, who, by the force of their genius, have opened up new views of science, and thus contributed to the progress of human intellect, so often have they, likewise, afforded the occasion of checking its advancement, and of turning it from the straight path of improvement. Not that this result is to be imputed as a reproach to them, but simply because it is of the nature of man to be so affected. The views which influenced these men of genius, and which, consequently, lie at the foundation of their works, are rarely comprehended in their totality by those who have the names of these authors most frequently in their mouths. The many do not concern themselves to seize the ideal which a philosopher contemplated, and of which his actual works are only the imperfect representations; they appropriate to themselves only some of his detached apothegms and propositions, and of these compound, as they best can, a sort of system suited to their understanding, and which they employ as a talisman in their controversies with others. As their reason is thus a captive to authority, and, therefore, unable to exert its native freedom, they, consequently, catch up the true and the false without discrimination, and remain always at the point of progress where they had been placed by their leaders. In their hands a system of living truths becomes a

mere petrified organism; and they require that the whole science shall become as dead and as cold as their own idol. Such was Plato's doctrine in the hands of the Platonists; such was Aristotle's philosophy in the hands of the Schoolmen; and the history of modern systems affords equally the same result.

So much for the first genus into which the Sources of Error are divided.

LECTURE III.—MODIFIED STOICHEIOLOGY.

SECTION II.—ERROR—ITS CAUSES AND REMEDIES.

A.—GENERAL CIRCUMSTANCES—SOCIETY.

B.—AS IN POWERS OF COGNITION, FEELING, AND DESIRE.

I.—AFFECTIONS—PRECIPITANCY—SLOTH—HOPE AND FEAR—SELF-LOVE.

Recapitulation.

In our last Lecture, we entered on the consideration of the various sources of Error. These, I stated, may be conveniently reduced to four heads, and consist, 1°, In the General Circumstances which modify the intellectual character of the individual; 2°, In the Constitution, Habits, and Reciprocal Relations of his powers of Cognition, Feeling, and Desire; 3°, In the language which he employs as an Instrument of Thought and a Medium of Communication; and, 4°, In the nature of the Objects themselves about which his knowledge is conversant.

Of these, I then gave you a general view of the nature of those occasions of Error, which originate in the circumstances under the influence of which the character and opinions of man are determined for him as a member of society. Under this head I stated, that, as man is destined by his Creator to fulfil the end of his existence in society, he is wisely furnished with a disposition to imitate those

among whom his lot is cast, and thus conform himself to whatever section of human society he may by birth belong, or of which he may afterwards become a member. The education we receive, nay the very possibility of receiving education at all, supposes to a certain extent the passive infusion of foreign and traditionary opinions. For as man is compelled to think much earlier than he is able to think for himself,—all education necessarily imposes on him many opinions which, whether in themselves true or false, are, in reference to the recipient, only prejudices; and it is even only a small number of mankind who at a later period are able to bring these obtruded opinions to the test of reason, and by a free exercise of their own intelligence to reject them if found false, or to acknowledge them if proved true.

But while the mass of mankind thus remain, during their whole lives, only the creatures of the accidental circumstances which have concurred to form for them their habits and beliefs; the few who are at last able to form opinions for themselves, are still dependent, in a great measure, on the unreasoning judgment of the many. Public opinion, hereditary custom, despotically impose on us the capricious laws of propriety and manners. The individual may possibly, in matters of science, emancipate himself from their servitude; in the affairs of life he must quietly submit himself to the yoke. The only freedom he can here prudently manifest, is to resign himself with a consciousness that he is a slave not to reason but to conventional accident. And while he conforms himself to the usages of his own society, he will be tolerant to those of others. In this respect his maxim will be that of the Scythian prince: "With you such may be the custom—with us it is different."

So much for the general nature of the influence to which we are exposed from the circumstances of Society; it now remains to say what are the means by which this influence, as a source of error, may be counteracted.

Means by which the influence of society, as a source of error, may be counteracted.

It has been seen that, in consequence of the manner in which our opinions are formed for us by the accidents of society, our imposed and supposed knowledge is a confused medley of truths and errors. Here it is evidently necessary to institute a critical examination of the contents of this knowledge. Descartes proposes that, in order to discriminate, among our prejudiced opinions, the truths from the errors, we ought to commence by doubting all. This has exposed him to much obloquy and clamor, but most unjustly. The doctrine of Descartes has nothing skeptical or offensive; for he only maintains that it behooves us to examine all that has been inculcated on us from infancy, and under the masters to whose authority we have been subjected, with the same attention and circumspection which we accord to dubious questions. In fact there is nothing in the precept of Descartes, which had not been previously enjoined by other philosophers. Of these I formerly quoted to you several, and among others the remarkable testimonies of Aristotle, St. Augustin, and Lord Bacon.

Necessary to institute a critical examination of the contents of our knowledge.

Descartes,—his precept.

But although there be nothing reprehensible in the precept of Descartes, as enounced by him, it is of less practical utility in consequence of no account being taken of the circumstances which condition and modify its application. For, in the first place, the judgments to be

Conditions which modify its application.

examined ought not to be taken at random, but selected on a principle, and arranged in due order and dependence. But this requires no ordinary ability, and the distribution of things into their proper classes is one of the last and most difficult fruits of philosophy. In the second place, there are among our prejudices, or pretended cognitions, a great many hasty conclusions, the investigation of which requires much profound thought, skill, and acquired knowledge. Now, from both of these considerations, it is evident that to commence philosophy by such a review, it is necessary for a man to be a philosopher before he can attempt to become one. The precept of Descartes is, therefore, either unreasonable, or it is too unconditionally expressed. And this latter alternative is true.

A gradual and progressive abrogation of prejudices all that can be required of the student of philosophy.

What can be rationally required of the student of philosophy, is not a preliminary and absolute, but a gradual and progressive abrogation, of prejudices. It can only be required of him, that, when, in the course of his study of philosophy, he meets with a proposition which has not been already sufficiently sifted,—(whether it has been elaborated as a principle or admitted as a conclusion),—he should pause, discuss it without prepossession, and lay aside for future consideration all that has not been subjected to a searching scrutiny. The precept of Descartes, when rightly explained, corresponds to that of St. Paul: "If any man among you seemeth to be wise in this world, let him become a fool, that he may be wise;" that is, let him not rely more on the opinions in which he has been brought up, and in favor of which he and those around him are prejudiced, than on so many visions of imagination; and let him examine them with the

same circumspection as if he were assured that they contain some truth among much falsehood and many extravagances.

Proceeding now to the second class of the Sources of Error, which are found in the Mind itself, I shall commence with the following paragraph:

¶ V. The Sources of Error which arise from the Constitution, Habits, and Reciprocal Relations of the powers of Cognition, Feeling, and Desire, may be subdivided into two kinds. The first of these consists in the undue preponderance of the Affective Elements of mind (the Desires and Feelings) over the Cognitive; the second, in the weakness or inordinate strength of some one or other of the Cognitive Faculties themselves.

Par. V. II. Source of Error arising from the powers of Cognition, Feeling, and Desire,—of two kinds.

Affection is that state of mind in which the Feelings and Desires exert an influence not under the control of reason; in other words, a tendency by which the intellect is impeded in its endeavor to think an object as that object really is, and compelled to think it in conformity with some view prescribed by the passion or private interest of the subject thinking.

Explication.

I. Preponderance of Affection over Cognition.

The human mind, when unruffled by passion, may be compared to a calm sea. A calm sea is a clear mirror, in which the sun and clouds, in which the forms of heaven and earth, are reflected back precisely as they are presented. But let a wind arise, and the smooth, clear surface of the water is lifted into billows and agitated into foam. It no more reflects the sun and clouds, the forms of heaven and earth, or it reflects them only as distorted and broken images. In

Influence of Passion on the Mind.

like manner, the tranquil mind receives and reflects the world without as it truly is; but let the wind of passion blow, and every object is represented, not as it exists, but in the colors and aspects and partial phases in which it pleases the subject to regard it.

Boethius quoted.

The state of passion and its influence on the Cognitive Faculties are truly pictured by Boethius :—

" *Nubibus atris*
Condita nullum
Fundere possunt
Sidera lumen.
Si mare volvens
Turbidus auster
Misceat æstum,
Vitrea dudum,
Cernere verum,
Tramite recto
Carpere callem :
Gaudia pelle,
Pelle timorem,
Parque serenis
Unda diebus,
Mox resoluto
Sordida cœno,
Visibus obstat.
. . . . .
Tu quoque si vis
Lumine claro
Spemque fugato,
Nec dolor adsit,
Nubila mens est,
Vinctaque frenis,
Hæc ubi regnant."

Every error consists in this,—that we take something for non-existent, because we have not become aware of its existence, and that, in place of this existent something, we fill up the premises of a probable reasoning with something else.

Error limited to Probable Reasoning.

I have here limited the possibility of error to Probable Reasoning, for, in Intuition and Demonstration, there is but little Possibility of important error. Hobbes indeed asserts that had it been contrary to the interest of those in authority, that the three angles of a triangle should be equal to two right angles, this truth would have been long ago proscribed as heresy, or as high treason. This may be an ingenious illustration of the blind tendency of the passions to subjugate intelligence; but we should take it for more than

was intended by its author, were we to take it as more than an ingenious exaggeration. Limiting, therefore, error to probable inference (and this constitutes, with the exception of a comparatively small department, the whole domain of human reasoning), we have to inquire, How do the Passions influence us to the assumption of false premises? To estimate the amount of probability for or against a given proposition, requires a tranquil, an unbiassed, a comprehensive consideration, in order to take all the relative elements of judgment into due account. But this requisite state of mind is disturbed when any interest, any wish, is allowed to interfere.

¶ VI. The disturbing Passions may be reduced to four: Precipitancy, Sloth, Hope and Fear, Self-love.

Par. VI. The Passions, as sources of Error,—reduced to four.

1°, A restless anxiety for a decision begets impatience, which decides before the preliminary inquiry is concluded. This is precipitancy.

2°, The same result is the effect of Sloth, which dreams on in conformity to custom, without subjecting its beliefs to the test of active observation.

3°, The restlessness of Hope or Fear impedes observation, distracts attention, or forces it only on what interests the passion;—the sanguine looking on only what harmonizes with his hopes, the diffident only on what accords with his fears.

4°, Self-love perverts our estimate of probability by causing us to rate the grounds of judgment, not according to their real influence on the truth of the decision, but according to their bearing on our personal interests therein.

In regard to Impatience or Precipitation,—"all is the cause of this which determines our choice on one side rather than another. An imagination excites pleasure, and because it excites pleasure we yield ourselves up to it. We suppose, for example, that we are all that we ought to be, and why? Because this supposition gives us pleasure. This, in some dispositions, is one of the greatest obstacles to improvement; for he who entertains it, thinks there is no necessity to labor to become what he is already. "I believe," says Seneca, "that many had it in their power to have attained to wisdom, had they not been impeded by the belief that wisdom they had already attained. '*Multos puto ad sapientiam potuisse pervenire, nisi putassent se pervenisse.*'" Erasmus gives the following as the principal advice to a young votary of learning in the conduct of his studies: "To read the most learned books, to converse with the most learned men; but, above all, never to conceit that he himself was learned."

Explication.
1. Precipitancy.

Seneca.

Erasmus.

"From the same cause, men flatter themselves with the hope of dying old, although few attain to longevity. The less probable the event, the more certain are they of its occurrence; and why? Because the imagination of it is agreeable. '*Decrepiti senes paucorum annorum accessionem votis mendicant; minores natu seipsos esse fingunt; mendacio sibi blandiuntur; et tam libenter fallunt, quam si fata una decipiant.*'" "Preachers," says Montaigne, "are aware that the emotion which arises during their sermons animates themselves to belief, and we are conscious that when roused to anger we apply ourselves more intently to the defence of our

Illustrations.

From Seneca.

From Montaigne.

thesis, and embrace it with greater vehemence and approbation, than we did when our mind was cool and unruffled. You simply state your case to an advocate; he replies with hesitation and doubt; you are aware that it is indifferent to him whether he undertakes the defence of the one side or of the other; but have you once fee'd him well to take your case in hand; he begins to feel an interest in it; his will is animated. His reason and his science become also animated in proportion. Your case presents itself to his understanding as a manifest and indubitable truth; he now sees it in a wholly different light, and really believes that you have law and justice on your side." It is proper to observe that Montaigne was himself a lawyer,—he had been a counsellor of the Parliament of Bordeaux.

Precipitate Dogmatism and phases of the same disposition.

It might seem that Precipitate Dogmatism and an inclination to Skepticism were opposite characters of mind. They are, however, closely allied, if not merely phases of the same disposition. This is indeed confessed by the Skeptic Montaigne: "The most uneasy condition for me is to be kept in suspense on urgent occasions, and to be agitated between fear and hope. Deliberation, even in things of lightest moment, is very troublesome to me; and I find my mind more put to it, to undergo the various tumbling and tossing of doubt and consultation, than to set up its rest, and to acquiesce in whatever shall happen, after the die is thrown. Few passions break my sleep; but of deliberations, the least disturbs me."

Remedy for Precipitation.

Precipitation is no incurable disease. There is for it one sure and simple remedy, if properly applied. It is only required, to speak with Confucius, manfully to restrain the wild horse of precipitancy by the curb of consideration,—

to weigh the reasons of decision, each and all, in the balance of cool investigation, not to allow ourselves to decide until a clear consciousness has declared these reasons to be true,—to be sufficient; and, finally, to throw out of account the suffrages of self-love, of prepossession, of passion, and to admit only those of reflection, of experience, and of evidence. This remedy is certain and effectual. In theory it is satisfactory, but its practical application requires a moral resolution, for the acquisition of which no precept can be given.

In the second place, "Sloth is likewise a cause of precipitation, and it deserves the more attention as it is a cause of error extremely frequent, and one of which we are ourselves less aware, and which is less notorious to others. We feel it fatiguing to continue an investigation, therefore we do not pursue it; but as it is mortifying to think that we have labored in vain, we easily admit the flattering illusion that we have succeeded. By the influence of this disposition it often happens, that, after having rejected what first presented itself,—after having rejected a second time and a third time what subsequently turned up, because not sufficiently applicable or certain, we get tired of the investigation, and perhaps put up with the fourth suggestion, which is not better, haply even worse, than the preceding; and this simply because it has come into the mind when more exhausted and less scrupulous than it was at the commencement." "The volition of that man," says Seneca, "is often frustrated, who undertakes not what is easy, but who wishes what he undertakes to be easy. As often as you attempt anything, compare together yourself, the end which you propose, and the means by which it is to be accomplished.

2. Sloth.

Seneca quoted.

For the repentance of an unfinished work will make you rash. And here it is of consequence whether a man be of a fervid or of a cold, of an aspiring or of a humble, disposition."

Its remedy.

To remedy this failing it is necessary, in conformity with this advice of Seneca, to consult our forces, and the time we can afford, and the difficulty of the subjects on which we enter. We ought to labor only at intervals, to avoid the tedium and disquiet consequent on unremitted application; and to adjourn the consideration of any thought which may please us vehemently at the moment, until the prepossession in its favor has subsided with the animation which gave it birth.

3. Hope and Fear.

The two Causes of premature judgment—the affections of Impatience and Sloth—being considered, I pass on to the third principle of Passion, by which the intellect is turned aside from the path of truth,—I mean the disturbing influence of Hope and Fear. These passions, though reciprocally contrary, determine a similar effect upon the deliberations of the Understanding, and are equally unfavorable for the interest of truth. In forming a just conclusion upon a question of probable reasoning, that is, where the grounds of decision are not few, palpable, and of determinate effect,—and such questions may be said to be those alone on which differences of opinion may arise, and are, consequently, those alone which require for their solution any high degree of observation and ingenuity,—in such questions hope and fear exert a very strong and a very unfavorable influence. In these questions it is requisite, in the first place, to seek out the premises; and, in the second, to draw the conclusion. Of these requisites the first is the more important, and it is also by far the more difficult.

How Hope and Fear operate unfavorably on the Understanding.

Now the passions of Hope and Fear operate severally to prevent the intellect from discovering all the elements of decision, which ought to be considered in forming a correct conclusion, and cause it to take into account those only which harmonize with that conclusion to which the actuating passion is inclined. And here the passion operates in two ways. In the first place, it tends so to determine the associations of thought, that only those media of proof are suggested or called into consciousness, which support the conclusion to which the passion tends. In the second place, if the media of proof by which a counter conclusion is supported are brought before the mind, still the mind is influenced by the passion to look on their reality with doubt, and, if such cannot be questioned, to undervalue their inferential importance; whereas it is moved to admit, without hesitation, those media of proof which favor the conclusion in the interest of our hope or fear, and to exaggerate the cogency with which they establish this result. Either passion looks exclusively to a single end, and exclusively to the means by which that single end is accomplished. Thus the sanguine temperament, or the mind under the habitual predominance of hope, sees only and magnifies all that militates in favor of the wished-for consummation, which alone it contemplates; whereas the melancholic temperament, or the mind under the habitual predominance of fear, is wholly occupied with the dreaded issue, views only what tends to its fulfilment, while it exaggerates the possible into the probable, the probable into the certain. Thus it is that whatever conclusion we greatly hope or greatly fear, to that conclusion we are disposed to leap; and it has become almost proverbial, that men

lightly believe both what they wish, and what they dread, to be true.

But the influence of Hope on our judgments, inclining us to find whatever we wish to find, in so far as this arises from the illusion of Self-love, is comprehended in this,—the fourth cause of error,—to which I now proceed.

4. Self-love.

Self-love, under which I include the dispositions of Vanity, Pride, and, in general, all those which incline us to attribute an undue weight to those opinions in which we feel a personal interest, is by far the most extensive and influential in the way of reason and truth. In virtue of this principle, whatever is ours—whatever is adopted or patronized by us, whatever belongs to those to whom we are attached is either gratuitously clothed with a character of truth, or its pretensions to be accounted true are not scrutinized with the requisite rigor and impartiality. I am a native of this country, and, therefore, not only is its history to me a matter of peculiar interest, but the actions and character of my countrymen are viewed in a very different light from that in which they are regarded by a foreigner. I am born and bred a member of a religious sect, and because they constitute my creed, I find the tenets of this sect alone in conformity to the Word of God. I am the partisan of a philosophical doctrine, and am, therefore, disposed to reject whetever does not harmonize with my adopted system.

Aristotle,—his precept.

"It is the part of a philosopher," says Aristotle, "inasmuch as he is a philosopher, to subjugate self-love, and to refute, if contrary to truth, not only the opinions of his friends, but the doctrines which he himself may have professed." It is certain, however, that philosophers—for philosophers are

men—have been too often found to regulate their conduct by the same opposite principle. That man pretended to the name of philosopher, who scrupled not to declare that he would rather be in the wrong with Plato than in the right with his opponents. "Gisbert Voetius urged Mersennus to refute a work of Descartes' a year before the book appeared, and before he had himself the means of judging whether the opinions it contained were right or wrong. A certain professor of philosophy in Padua came to Galileo, and requested that he would explain to him the meaning of the term *parallaxis;* which he wished, he said, to refute, having heard that it was opposed to Aristotle's doctrine, touching the relative situation of the comets. 'What!' answered Galileo, 'you wish to controvert a word the meaning of which you do not know!' Redi tells us that a sturdy Peripatetic of his acquaintance would never consent to look at the heavens through a telescope, lest he should be compelled to admit the existence of the new stars discovered by Galileo and others. The same Redi informs us that he knew another Peripatetic, a staunch advocate of the Aristotlean doctrine of equivocal generation, (a doctrine, by the way, which now again divides the physiologists of Europe), and who, in particular, maintained that the green frogs which appear upon a shower come down with the rain, who would not be induced himself to select and examine one of these frogs. And why? Because he was unwilling to be convicted of his error, by Redi showing him the green matter in the stomach, and its feculæ in the intestines of the animal." The spirit of the Peripatetic philosophy was, however, wholly misunderstood by these mistaken followers of Aristotle; for a true Aristotelian is one who listens

Illustrations of the influence of Self-love on our opinions.

rather to the voice of nature than to the precept of any master, and it is well expressed in the motto of the great French anatomist—*Riolanus est Peripateticus; credit ea, et ea tantum, quæ vidit.* From the same principle proceeds the abuse, and sometimes even the persecution, which the discoverers of new truths encounter from those who cherished opinions these truths subvert.

Self-love leads us to regard with favor the opinions of those to whom we are in any way attached.

In like manner, as we are disposed to maintain our own opinion, we are inclined to regard with favor the opinions of those to whom we are attached by love, gratitude, and other conciliatory affections. "We do not limit our attachment to the persons of our friends,—we love in a certain sort all that belongs to them; and as men generally manifest sufficient ardor in support of their opinions, we are led insensibly by a kind of sympathy to credit, to approve, and to defend these also, and that even more passionately than our friends themselves. We bear affection to others for various reasons. The agreement of tempers, of inclinations, of pursuits; their appearance, their manners, their virtue, the partiality which they have shown to us, the services we have received at their hands, and many other particular causes, determine and direct our love.

Malebranche adduced to this effect.

"It is observed by the great Malebranche, that if any of our friends,—any even of those we are disposed to love,—advance an opinion, we forthwith lightly allow ourselves to be persuaded of its truth. This opinion we accept and support, without troubling ourselves to inquire whether it be conformable to fact, frequently even against our conscience, in conformity to the darkness and confusion of our intellect, to

the corruption of our heart, and to the advantages which we hope to reap from our facility and complaisance."

The influence of this principle is seen still more manifestly when the passion changes; for though the things themselves remain unaltered, our judgments concerning them are totally reversed. How often do we behold persons who cannot, or will not, recognize a single good quality in an individual from the moment he has chanced to incur their dislike, and who are even ready to adopt opinions, merely because opposed to others maintained by the object of their aversion? The celebrated Arnauld goes so far even as to assert, that men are naturally envious and jealous; that it is with pain they endure the contemplation of others in the enjoyment of advantages which they do not themselves possess; and, as the knowledge of truth and the power of enlightening mankind is one of these, that they have a secret inclination to deprive them of that glory. This accordingly often determines them to controvert without a ground the opinions and discoveries of others. Self-love accordingly often argues thus:—'This is an opinion which I have originated, this is an opinion, therefore, which is true;' whereas the natural malignity of man not less frequently suggests such another: 'It is another than I who has advanced this doctrine; this doctrine is, therefore, false.'

This shown especially when the passion changes.

Arnauld holds that man is naturally envious.

We may distinguish, however, from malignant or envious contradiction another passion, which, though more generous in its nature and not simply a mode of Self-love, tends, nevertheless, equally to divert us from the straight road of truth,—I mean Pugnacity, or the love of Disputation.

The love of Disputation.

Under the influence of this passion, we propose as our end victory, not truth. We insensibly become accustomed to find a reason for any opinion, and, in placing ourselves above all reasons, to surrender our belief to none. Thus it is why two disputants so rarely ever agree, and why a question is seldom or never decided in a discussion, where the combative dispositions of the reasoners have once been roused in activity. In controversy it is always easy to find wherewithal to reply; the end of the parties is not to avoid error, but to impose silence; and they are less ashamed of continuing wrong than of confessing that they are not right.

These affections may be said to be the immediate causes of all error. Other causes there are, but not immediate. In so far as Logic detects the sources of our false judgments and shows their remedies, it must carefully inculcate that no precautionary precept for particular cases can avail, unless the inmost principle of the evil be discovered, and a cure applied. You must, therefore, as you would remain free from the hallucination of false opinion, be convinced of the absolute necessity of following out the investigation of every question calmly and without passion. You must learn to pursue, and to estimate, truth without distraction or bias. To this there is required, as a primary condition, the unshackled freedom of thought, the equal glance which can take in the whole sphere of observation, the cool determination to pursue the truth whithersoever it may lead; and, what is still more important, the disposition to feel an interest in truth and in truth alone. If perchance some collateral interest may first prompt us to the inquiry, in our general interest for

These affections the immediate causes of all error.

Preliminary conditions requisite for the efficiency of precepts against the sources of error.

truth we must repress,—we must forget, this interest, until the inquiry be concluded. Of what account are the most venerated opinions if they be untrue? At best they are only venerable delusions. He who allows himself to be actuated in his scientific procedure by any partial interest, can never obtain a comprehensive survey of the whole he has to take into account, and always, therefore, remains incapable of discriminating, with accuracy, error from truth. The independent thinker must, in all his inquiries, subject himself to the genius of truth,—must be prepared to follow her footsteps without faltering or hesitation. In the consciousness that truth is the noblest of ends, and that he pursues this end with honesty and devotion, he will dread no consequences,—for he relies upon the truth. Does he compass the truth, he congratulates himself upon his success; does he fall short of its attainment, he knows that even his present failure will ultimately advance him to the reward he merits. Err he may, and that perhaps frequently, but he will never deceive himself. We cannot, indeed, rise superior to our limitary nature, we cannot, therefore, be reproached for failure; but we are always responsible for the calmness and impartiality of our researches, and these alone render us worthy of success. But though it be manifest, that to attain the truth we must follow whithersoever the truth may lead, still men in general are found to yield not an absolute, but only a restricted, obedience to the precept. They capitulate, and do not unconditionally surrender. I give up, but my cherished dogma in religion must not be canvassed, says one;—my political principles are above inquiry, and must be exempted, says a second;—my country is the land of lands, this cannot be disallowed, cries a third;—my order, my

vocation, is undoubtedly the noblest, exclaim a fourth and fifth;—only do not require that we should confess our having erred, is the condition which many insist on stipulating. Above all, that resolve of mind is difficult, which is ready to surrender all fond convictions, and is prepared to recommence investigation the moment that a fundamental error in the former system of belief has been detected. These are the principal grounds why, among men, opinion is so widely separated from opinion; and why the clearest demonstration is so frequently for a season frustrated of victory.

Par. VII. Rules against Errors from the Affections.

¶ VII. Against the Errors which arise from the Affections, there may be given the three following rules:

1°, When the error has arisen from the influence of an active affection, the decisive judgment is to be annulled; the mind is then to be freed, as far as possible, from passion, and the process of inquiry to be recommenced as soon as the requisite tranquility has been restored.

2°, When the error has arisen from a relaxed enthusiasm for knowledge, we must reanimate this interest by a vivid representation of the paramount dignity of truth, and of the lofty destination of our intellectual nature.

3°, In testing the accuracy of our judgments, we must be particularly suspicious of those results which accord with our private inclinations and predominant tendencies.

These rules require no comment.

LECTURE IV.—MODIFIED STOICHEIOLOGY.

SECTION II.—ERROR,—ITS CAUSES AND REMEDIES.

B.—AS IN THE COGNITIONS, FEELINGS, AND DESIRES.

II.—WEAKNESS AND DISPROPORTIONED STRENGTH OF THE FACULTIES OF KNOWLEDGE.

Weakness and Disproportioned Strength of the Faculties of Knowledge.

I now go on to the Second Head of the class of Errors founded on the Natural Constitution, the Acquired Habits, and the Reciprocal Relations of our Cognitive and Affective Powers, that is, to the Causes of Error which originate in the Weakness or Disproportioned Strength of one or more of our Faculties of Knowledge themselves.

Neglect of the Limited Nature of the Human Intellect a source of error.

Here, in the first place, I might consider the errors which have arisen from the Limited Nature of the Human Intellect in general,—or rather from the mistakes that have been made by philosophers in denying or not taking this limited nature into account. The illustration of this subject is one which is relative to, and supposes an acquaintance with, some of the abstrucest speculations in Philosophy, and which belong not to Logic, but to Metaphysics. I shall not, therefore, do more than

simply indicate at present, what it will be proper at another season fully to explain. It is manifest, that, if the human mind be limited,—if it only knows as it is conscious, and if it be only conscious, as it is conscious of contrast and opposition, of an ego and non-ego,—if this supposition, I say, be correct, it is evident that those philosophers are in error, who virtually assume that the human mind is unlimited, that is, that the human mind is capable of a knowledge superior to consciousness,—a cognition in which knowledge and existence—the Ego and non-Ego—God and the creature—are identical; that is, of an act in which the mind is the Absolute, and knows the Absolute. This philosophy, the statement of which, as here given, it would require a long commentary to make you understand, is one which has for many years been that dominant in Germany; it is called the *Philosophy of the Absolute*, or the *Philosophy of Absolute Identity*. This system, of which Schelling and Hegel are the great representatives, errs by denying the limitation of human intelligence without proof, and by boldly building its edifice on this gratuitous negation.

1. Philosophy of the Absolute.

But there are other forms of philosophy which err not in actually postulating the infinity of mind, but in taking only a one-sided view of its finitude. It is a general fact, which seems, however, to have escaped the observation of philosophers, that whatever we can positively compass in thought,—whatever we can conceive as possible,—in a word, the *omne cogitabile*, lies between two extremes or poles, contradictorily opposed, and one of which must consequently be true, but of neither of which repugnant opposites are we able to represent to our mind the possibility. To take one

2. A one-sided view of the finitude of mind.

example out of many: we cannot construe to the mind as possible the absolute commencement of time; but we are equally unable to think the possibility of the counter alternative,—its infinite or absolute non-commencement, in other words, the infinite regress of time. Now it is evident, that, if we looked merely at the one of these contradictory opposites and argued thus: whatever is inconceivable is impossible, the absolute commencement of time is inconceivable, therefore the absolute commencement of time is impossible; but on the principles of Contradiction and Excluded Middle, one or other of the two opposite contradictories must be true; therefore, as the absolute commencement of time is impossible, the absolute or infinite non-commencement of time is necessary:—I say, it is evident that this reasoning would be incompetent and one-sided, because it might be converted; for, by the same one-sided process, the opposite conclusion might be drawn in favor of the absolute commencement of time.

Illustrated by reference to the two contradictories,—the absolute commencement, and the infinite non-commencement of Time.

Now, the unilateral and incompetent reasoning which I have here supposed in the case of time, is one of which the Necessitarian is guilty in his argument to prove the impossibility of human volitions being free. He correctly lays down, as the foundation of his reasoning, two propositions which must at once be allowed: 1°, That the notion of the liberty of volition involves the supposition of an absolute commencement of volition, that is, of a volition which is a cause, but is not itself, *qua* cause, an effect. 2°, That the absolute commencement of a volition, or of aught else, cannot be conceived,

The same principle exemplified in the case of the Necessitarian Argument against the Freedom of the Human Will.

that is, cannot be directly or positively thought as possible. So far he is correct; but when he goes on to apply these principles by arguing (and be it observed this syllogism lies at the root of all the reasonings for necessity), *Whatsoever is inconceivable is impossible; but the supposition of the absolute commencement of volition is inconceivable; therefore, the supposition of the absolute commencement of volition (the condition of free-will) is impossible,*—we may here demur to the sumption, and ask him,—Can he positively conceive the opposite contradictory of the absolute commencement, that is, an infinite series of relative non-commencements? If he answers, as he must, that he can not, we may again ask him,—By what right he assumed as a self-evident axiom for his sumption, the proposition—that *whatever is inconceivable is impossible*, or by what right he could subsume his minor premise, when by his own confession he allows that the opposite contradictory of his minor premise, that is, the very proposition he is apagogically proving, is, likewise, inconceivable, and, therefore, on the principle of his sumption, likewise impossible.

And in the case of the Libertarian Argument in behalf of Free-will.

The same inconsequence would equally apply to the Libertarian, who should attempt to prove that free-will must be allowed, on the ground that its contradictory opposite is impossible, because inconceivable. He cannot prove his thesis by such a process; in fact, by all speculative reasoning from the conditions of thought, the two doctrines are *in æquilibrio;*—both are equally possible,—both are equally inconceivable. It is only when the Libertarian descends to arguments drawn from the fact of the Moral Law and its conditions, that he

is able to throw in reasons which incline the balance in his favor.

On these matters I, however, at present, only touch, in order to show you under what head of Error these reasonings would naturally fall.

Weakness or disproportioned strength of the several Cognitive Faculties,—a source of Error.

Leaving, therefore, or adjourning, the consideration of the imbecility of the human intellect in general, I shall now take into view, as a source of logical error, the Weakness or Disproportioned Strength of the several Cognitive Faculties. Now, as the Cognitive Faculties in man consist partly of certain Lower Powers, which he possesses in common with other sensible existences, namely, the Presentative, the Retentive, the Representative and the Reproductive Faculties, and partly of certain higher Powers, in virtue of which he enters into the rank of intelligent existences, namely, the Elaborative and Regulative Faculties,—it will be proper to consider the powers of these two classes severally in succession, in so far as they may afford the causes or occasions of error.

Cognitive Faculties of two classes, a Lower and a Higher.

I. The Lower Class,—1. The Presentative Faculty.

Of the lower class, the first faculty in order is the Presentative or Acquisitive Faculty. This, as you remember, is divided into two, viz., into the Faculty which presents us with the phenomena of the outer world, and into the faculty which presents us with the phenomena of the inner. The former is External Perception, or External Sense; the latter is Self-consciousness, Internal Perception, or Internal Sense. I commence, therefore, with the Faculty of External Perception, in relation to which I give you the following paragraph:

¶ VII. When aught is presented through the outer senses, there are two conditions necessary for its adequate perception :— 1°, The relative Organs must be present, and in a condition to discharge their functions ; and 2°, The objects themselves must bear a certain relation to these organs, so that the latter shall be suitably affected, and thereby the former suitably apprehended. It is possible, therefore, that, partly through the altered condition of the organs, partly through the altered situation of the objects, dissimilar presentations of the same, and similar presentations of different, objects, may be the result.

Par. VII. (a) External Perception,—as a source of Error.

In the first place, without the organs specially subservient to External Perception,—without the eye, the ear, etc., sensible perceptions of a precise and determinate character, such, for example, as color or sound, are not competent to man. In the second place, to perform their functions, these organs must be in a healthy or normal state ; for if this condition be not fulfilled, the presentations which they furnish are null, incomplete, or false. But, in the third place, even if the organs of sense are sound and perfect, the objects to be presented and perceived must stand to these organs in a certain relation,—must bear to them a certain proportion ; for, otherwise, the objects cannot be presented at all, or cannot be perceived without illusion. The sounds, for example, which we are to hear, must neither be too high nor too low in quality ; the bodies which we are to see, must neither be too near nor too distant,—must neither be too feebly nor too intensely illuminated. In relation to the second condition,

Explication.

Conditions of the adequate activity of External Perception.

there are given, in consequence of the altered state of the organs, on the one hand, different presentations of the same object;—thus to a person who has waxed purblind, his friend appears as an utter stranger, the eye now presenting its objects with less clearness and distinctness. On the other hand, there are given the same, or undistinguishably similar, presentations of different objects;—thus to a person in the jaundice, all things are presented yellow. In relation to the third condition, from the altered position of objects, there are, in like manner, determined, on the one hand, different presentations of the same objects,—as when the stick which appears straight in the air appears crooked when partially immersed in water; and, on the other hand, identical presentations of different objects, as when a man and a horse appear in the distance to be so similar, that the one cannot be discriminated from the other. In all these cases, these illusions are determined,—illusions which may easily become the occasions of false judgments.

Possible illusions of the Senses.

In regard to the detection of such illusions and obviating the error to which they lead, it behooves us to take the following precautions. We must, in the first place, examine the state of the organ. If found defective, we must endeavor to restore it to perfection; but if this cannot be done, we must ascertain the extent and nature of the evil, in order to be upon our guard in regard to quality and degree of the false presentation.

Precautions with a view to the detection of illusions of the Senses, and obviating the errors to which they lead.

In the second place, we must examine the relative situation of the object, and if this be not accommodated to the organ, we must either obviate the disproportion and

remove the media which occasion the illusion, or repeat the observation under different circumstances, compare these, and thus obtain the means of making an ideal abstraction of the disturbing causes.

In regard to the other Presentative Faculty,—the Faculty of Self-consciousness,—Internal Perception, or Internal Sense, as we know less of the material conditions which modify its action, we are unable to ascertain so precisely the nature of the illusions of which it may be the source. In reference to this subject you may take the following paragraph :

¶ VIII. The faculty of Self-consciousness, or Internal Sense, is subject to various changes, which either modify our apprehensions of objects, or influence the manner in which we judge concerning them. In so far, therefore, as false judgments are thus occasioned, Self-consciousness is a source of error.

Par. VIII. (b) Self-consciousness,—as a source of Error.

It is a matter of ordinary observation, that the vivacity with which we are conscious of the various phenomena of mind, differs not only at different times, in different states of health, and in different degrees of mental freshness and exhaustion, but, at the same time, differs in regard to the different kinds of these phenomena themselves. According to the greater or less intensity of this faculty, the same thoughts of which we are conscious are, at one time, clear and distinct, at another, obscure and confused. At one time we are almost wholly incapable of reflection, and every act of self attention is forced and irksome, and differences the most marked pass unnoticed ; while, at another our self-consciousness is alert, all its applications pleasing,

Explication. Self-consciousness varies in intensity.

and the most faint and fugitive phenomena arrested and observed. On one occasion, Self-consciousness, as a reflective cognition, is strong; on another, all reflection is extinguished in the intensity of the direct consciousness of feeling or desire. In one state of mind our representations are feeble; in another, they are so lively that they are mistaken for external realities. Our self-consciousness may thus be the occasion of frequent error; for, according to its various modifications, we may form the most opposite judgments concerning the same things,—pronouncing them, for example, now to be agreeable, now to be disagreeable, according as our Internal Sense is variously affected.

The next is the Retentive or Conservative Faculty,—Memory strictly so called; in reference to which I give you the following paragraph:

¶ IX. Memory, or the Conservative Faculty, is the occasion of Error, both when too weak and when too strong. When too weak, the complement of cognitions which it retains is small and indistinct, and the Understanding or Elaborative Faculty is, consequently, unable adequately to judge concerning the similarity and differences of its representations and concepts. When too strong, the Understanding is overwhelmed with the multitude of acquired cognitions simultaneously forced upon it, so that it is unable calmly and deliberately to compare and discriminate these.

Par. IX. 2. Memory,—as a source of Error.

That both these extremes,—that both the insufficient and the superfluous vigor of the Conservative Faculty are severally the sources of Error, it will not require many observations to make apparent.

Explication.

Feeble Memory.

In regard to a feeble memory, it is manifest that a multitude of false judgments must inevitably arise from an incapacity in this faculty to preserve the observations committed to its keeping. In consequence of this incapacity, if a cognition be not wholly lost, it is lost at least in part, and the circumstances of time, place, persons and things confounded with each other. For example,—I may recollect the tenor of a passage I have read, but from defect of memory may attribute to one author what really belongs to another. Thus a botanist may judge two different plants to be identical in species, having forgotten the differential characters by which they were discriminated; or he may hold the same plant to be two different species, having examined it at different times and places.

Strong Memory.

Though nothing could be more erroneous than a general and unqualified decision, that a great memory is incompatible with a sound judgment, yet it is an observation confirmed by the experience of all ages and countries, not only that a great memory is no condition of high intellectual talent, but that great memories are very frequently found in combination with comparatively feeble powers of thought. The truth seems to be, that where a vigorous memory is conjoined with a vigorous intellect, not only does the force of the subsidiary faculty not detract from the strength of the principal, but, on the contrary, tends to confer on it a still higher power; whereas when the inferior faculty is disproportionately strong, that so far from nourishing and corroborating the superior, it tends to reduce this faculty to a lower level than that at which it would have stood, if united with a less overpowering subsidiary. The greater the magazine of

various knowledge which the memory contains, the better for the understanding, provided the understanding can reduce this various knowledge to order and subjection. A great memory is the principal condition of bringing before the mind many different representations and notions at once, or in rapid succession. This simultaneous or nearly simultaneous presence disturbs, however, the tranquil comparison of a small number of ideas, which, if it shall judge aright, the intellect must contemplate with a fixed and steady attention. Now, where an intellect possesses the power of concentration in a high degree, it will not be harrassed in its meditations by the officious intrusions of the subordinate faculties, however vigorous these in themselves may be, but will control their vigor by exhausting in its own operations the whole applicable energy of mind. Whereas where the inferior is more vigorous than the superior, it will, in like manner, engross in its own function the disposable amount of activity, and overwhelm the principal faculty with materials, many even in proportion as it is able to elaborate few. This appears to me the reason why men of strong memories are so often men of proportionally weak judgments, and why so many errors arise from the possession of a faculty, the perfection of which ought to exempt them from many mistaken judgments.

Remedies for these opposite extremes.

As to the remedy for these opposite extremes. The former—the imbecility of memory—can only be alleviated by invigorating the capacity of Retention through mnemonic exercises and methods; the latter,—the inordinate vigor of Memory,—by cultivating the Understanding to the neglect of the Conservative Faculty. It will, likewise, be necessary to be upon our guard against the errors originating in these

counter sources. In the one case distrusting the accuracy of facts, in the other, the accuracy of their elaboration.

3. The Reproductive Faculty.

The next faculty is the Reproductive. This, when its operation is voluntarily exerted, is called *Recollection* or *Reminiscence;* when it energizes spontaneously or without volition, it is called *Suggestion.* The laws by which it is governed in either case, but especially in the latter, are called the *Laws of Mental Association.* This Reproductive Faculty, like the Retentive, is the cause of error, both if its vigor be defective, or if it be too strong. I shall consider Recollection and Suggestion severally and apart. In regard to the former I give you the following paragraph.

Par. X. (a) Reminiscence—as a source of Error.

¶ X. The Reproductive Faculty, in so far as it is voluntarily exercised, as Reminiscence, becomes a source of Error, as it is either too sluggish or too prompt, precisely as the Retentive Faculty, combined with which it constitutes Memory in the looser signification.

Explication. Reminiscence,—its undue activity.

It is necessary to say very little in special reference to Reminiscence, for what was said in regard to the Conservative Faculty or Memory Proper in its highest vigor, was applicable to, and in fact supposed a corresponding degree of, the Reproductive. For, however great may be the mass of cognitions retained in the mind, that is, out of consciousness, but potentially capable of being called into consciousness, these can never of themselves oppress the Understanding by their simultaneous crowding or rapid succession, if the faculty by which they are revoked into consciousness be inert; whereas if this revocative faculty

be comparatively alert and vigorous, a smaller magazine of retained cognitions may suffice to harass the intellect with a ceaseless supply of materials too profuse for its capacity of elaboration.

Its inactivity.

On the other hand, the inactivity of our Recollection is a source of error, precisely as the weakness of our Memory proper; for it is of the same effect in relation to our judgments, whether the cognitions requisite for a decision be not retained in the mind, or whether, being retained, they are not recalled into consciousness by Reminiscence.

In regard to Suggestion, or the Reproductive Faculty operating spontaneously, that is, not in subservience to an act of Will,—I shall give you the following paragraph:

Par. XI. (b) Suggestion—as a source of Error.

¶ XI. As our Cognitions, Feelings, and Desires are connected together by what are called the *Laws of Association*, and as each link in the chain of thought suggests or awakens into consciousness some other in conformity to these Laws,—these Laws, as they bestow a strong subjective connection on thoughts and objects of a wholly arbitrary union, frequently occasion great confusion and error in our judgments.

Explication.

Even in methodical thinking, we do not connect all our thoughts intentionally and rationally, but many press forward into the train, either in consequence of some external impression, or in virtue of certain internal relations, which, however, are not of a logical dependency. Thus thoughts tend to suggest each other, which have reference to things of which we were previously cognizant as coëxistent, or as immediately con-

sequent, which have been apprehended as bearing a resemblance to each other, or which have stood together in reciprocal and striking contrast. This connection, though precarious and non-logical, is thus, however, governed by certain laws, which have been called the *Laws of Association*. These laws, which I have just enumerated, viz., the Law of Coëxistence or Simultaneity, the Law of Continuity or Immediate Succession, the Law of Similarity, and the Law of Contrast, are all only special modifications of one general law, which I would call the *Law of Redintegration;* that is, the principle according to which whatever has previously formed a part of one total act of consciousness, tends, when itself recalled into consciousness, to reproduce along with it the other parts of that original whole. But though these tendencies be denominated *laws*, the influence which they exert, though often strong and sometimes irresistible, is only contingent; for it frequently happens that thoughts which have previously stood to each other in one or other of the four relations do not suggest each other. The Laws of Association stand, therefore, on a very different footing from the laws of logical connection. But those Laws of Association, contingent though they be, exert a great and often a very pernicious influence upon thought, inasmuch as by the involuntary intrusion of representations into the mental chain which are wholly irrelevant to the matter in hand, there arises a perplexed and redundant tissue of thought, into which false characters may easily find admission, and in which true characters may easily be overlooked. But this is not all. For, by being once blended together in our consciousness, things really distinct in their nature tend again naturally to reassociate, and, at every repetition of this

conjunction, this tendency is fortified, and their mutual suggestion rendered more certain and irresistible.

Influence of Association in matters of Taste.

It is in virtue of this principle of Association and Custom, that things are clothed by us with the precarious attributes of deformity or beauty; and some philosophers have gone so far as to maintain that our principles of Taste are exclusively dependent on the accidents of Association. But if this be an exaggeration, it is impossible to deny that Association enjoys an extensive jurisdiction in the empire of taste, and, in particular, that fashion is almost wholly subject to its control.

Stewart quoted.

On this subject I may quote a few sentences from the first volume of Mr. Stewart's *Elements*. "In matters of Taste, the effects which we consider are produced on the mind itself, and are accompanied either with pleasure or with pain. Hence the tendency to casual association is much stronger than it commonly is with respect to physical events; and when such associations are once formed, as they do not lead to any important inconvenience, similar to those which result from physical mistakes, they are not so likely to be corrected by mere experience, unassisted by study. To this it is owing that the influence of association on our judgments concerning beauty and deformity, is still more remarkable than on our speculative conclusions; a circumstance which has led some philosophers to suppose that association is sufficient to account for the origin of these notions, and that there is no such thing as a standard of taste, founded on the principles of the human constitution. But this is undoubtedly pushing the theory a great deal too far. The association of ideas can never account for the origin of a

new notion, or of a pleasure essentially different from all the others which we know. It may, indeed, enable us to conceive how a thing indifferent in itself may become a source of pleasure, by being connected in the mind with something else which is naturally agreeable; but it presupposes, in every instance, the existence of those notions and those feelings which it is its province to combine; insomuch that, I apprehend, it will be found, wherever associations produce a change in our judgments on matters of taste, it does so by co-operating with some natural principle of the mind, and implies the existence of certain original sources of pleasure and uneasiness.

"A mode of dress, which at first appeared awkward, acquires, in a few weeks or months, the appearance of elegance. By being accustomed to see it worn by those whom we consider as models of taste, it becomes associated with the agreeable impressions which we receive from the ease and grace and refinement of their manners. When it pleases by itself, the effect is to be ascribed, not to the object actually before us, but to the impressions with which it has been generally connected, and which it naturally recalls to the mind.

"This observation points out the cause of the perpetual vicissitudes in dress, and in everything whose chief recommendation arises from fashion. It is evident that, as far as the agreeable effect of an ornament arises from association, the effect will continue only while it is confined to the higher orders. When it is adopted by the multitude, it not only ceases to be associated with ideas of taste and refinement, but it is associated with ideas of affectation, absurd imitation, and vulgarity. It is accordingly laid aside by the higher orders, who studiously avoid every cir-

cumstance in external appearance which is debased by low and common use; and they are led to exercise their invention in the introduction of some new peculiarities, which first become fashionable, then common, and last of all, are abandoned as vulgar.

"Our moral judgments, too, may be modified, and even perverted to a certain degree, in consequence of the operation of the same principle. In the same manner in which a person who is regarded as a model of taste may introduce, by his example, an absurd or fantastical dress; so a man of splendid virtues may attract some esteem also to his imperfections; and, if placed in a conspicuous situation, may render his vices and follies objects of general imitation among the multitude.

"'In the reign of Charles II.,' says Mr. Smith, 'a degree of licentiousness was deemed the characteristic of a liberal education. It was connected, according to the notions of those times, with generosity, sincerity, magnanimity, loyalty; and proved that the person who acted in this manner was a gentleman, and not a puritan. Severity of manners, and regularity of conduct, on the other hand, were altogether unfashionable, and were connected, in the imagination of that age, with cant, cunning, hypocrisy, and low manners. To superficial minds the vices of the great seem at all times agreeable. They connect them not only with the splendor of fortune, but with many superior virtues which they ascribe to their superiors; with the spirit of freedom and independency; with frankness, generosity, humanity, and politeness. The virtues of the inferior ranks of people, on the contrary,—their parsimonious frugality, their painful industry, and rigid adherence to rules, seem to them mean and disagreeable. They connect

them both with the meanness of the station to which these qualities commonly belong, and with many great vices which they suppose usually accompany them; such as an abject, cowardly, ill-natured, lying, pilfering disposition.'"

Condillac quoted on the influence of Association.

"In general," says Condillac, "the impression we experience in the different circumstances of life, makes us associate ideas with a force which renders them ever after for us indissoluble. We cannot, for example, frequent the society of our fellow-men without insensibly associating the notions of certain intellectual or moral qualities with certain corporeal characters. This is the reason why persons of a decided physiognomy please or displease us more than others; for a physiognomy is only an assemblage of characters, with which we have associated notions which are not suggested without an accompaniment of satisfaction or disgust. It is not, therefore, to be marvelled at that we judge men according to their physiognomy, and that we sometimes feel towards them at first sight aversion or inclination. In consequence of these associations, we are often vehemently prepossessed in favor of certain individuals, and no less violently disposed against others. It is because all that strikes us in our friends or in our enemies is associated with the agreeable or the disagreeable feeling which we severally experience; and because the faults of the former borrow always something pleasing from their amiable qualities; whereas the amiable qualities of the latter seem always to participate of their vices. Hence it is that these associations exert a powerful influence on our whole conduct. They foster our love or hatred; enhance our esteem or contempt; excite our gratitude or indignation; and produce those sympathies,—those antipathies, or those

capricious inclinations, for which we are sometimes sorely puzzled to render a reason. Descartes tells us that through life he had always found a strong predilection for squint eyes,—which he explains by the circumstance, that the nursery-maid by whom he had been kindly tended, and to whom as a child he was, consequently, much attached, had this defect." 'S Gravesande, I think it is, who tells us he knew a man, and a man otherwise of sense, who had a severe fall from a waggon; and thereafter he could never enter a waggon without fear and trembling, though he daily used, without apprehension, another and far more dangerous vehicle. A girl once and again sees her mother or maid fainting and vociferating at the appearance of a mouse; if she has afterwards to escape from danger, she will rather pass through flames than take a patent way, if obstructed by a *ridiculus mus*. A remarkable example of the false judgments arising from this principle of association, is recorded by Herodotus and Justin, in reference to the war of the Scythians with their slaves. The slaves, after they had repeatedly repulsed several attacks with arms, were incontinently put to flight when their masters came out against them with their whips.

I shall now offer an observation in regard to the appropriate remedy for this evil influence of Association

Only remedy for the influence of Association is the Philosophy of the Human Mind.

The only mean by which we can become aware of, counteract, and overcome, this besetting weakness of our nature, is Philosophy,—the Philosophy of the Human Mind; and this studied both in the consciousness of the individual, and in the history of the species. The philosophy of mind, as studied in the consciousness of the individual, exhibits to us the source and

nature of the illusion. It accustoms us to discriminate the casual, from the necessary, combinations of thought; it sharpens and corroborates our faculties, encourages our reason to revolt against the blind preformations of opinion, and finally enables us to break through the enchanted circle within which Custom and Association had enclosed us. But in the accomplishment of this end, we are greatly aided by the study of man under the various circumstances which have concurred in modifying his intellectual and moral character. In the great spectacle of history, we behold in different ages and countries the predominance of different systems of association, and these ages and countries are, consequently, distinguished by the prevalence of different systems of opinions. But all is not fluctuating; and, amid the ceaseless changes of accidental circumstances and precarious beliefs, we behold some principles ever active, and some truths always commanding a recognition. We thus obtain the means of discriminating, in so far as our unassisted reason is conversant about mere worldly concerns, between what is of universal and necessary certainty, and what is only of local and temporary acceptation; and, in reference to the latter, in witnessing the influence of an arbitrary association in imposing the most irrational opinions on our fellow-men, our eyes are opened, and we are warned of the danger from the same illusion to ourselves. And as the philosophy of man affords us at once the indication and the remedy of this illusion, so the philosophy of man does this exclusively and alone. Our irrational associations, our habits of groundless credulity and of arbitrary scepticism, find no medicine in the study of aught beyond the domain of mind itself.

As Goethe has well observed, "Mathematics remove no

prejudice; they cannot mitigate obstinacy, or temper party-spirit;" in a word, as to any moral influence upon the mind, they are absolutely null. Hence we may well explain the aversion of Socrates for these studies, if carried beyond a very limited extent.

The Representative Faculty, or Imagination Proper.

The next faculty in order is the Representative, or Imagination Proper, which consists in the greater or less power of holding up an ideal object in the light of consciousness. The energy of Representation, though dependent on Retention and Reproduction, is not to be identified with these operations. For though these three functions (I mean Retention, Reproduction, and Representation) immediately suppose, and are immediately dependent on each other, they are still manifestly discriminated as different qualities of mind, inasmuch as they stand to each other in no determinate proportion. We find, for example, in some individuals the capacity of Retention strong, but the Reproductive and Representative Faculties sluggish and weak. In others, again, the Conservative tenacity is feeble, but the Reproductive and Representative energies prompt and vivid; while in others the power of Reproduction may be vigorous, but what is recalled is never pictured in a clear and distinct consciousness. It will be generally, indeed, admitted, that a strong retentive memory does not infer a prompt recollection; and still more that a strong memory and a prompt recollection do not infer a vivid imagination. These, therefore, though variously confounded by philosophers, we are warranted, I think, in viewing as elementary qualities of mind, which ought to be theoretically distinguished. Limiting, therefore, the term *Imagination* to the mere Faculty of Representing in a more or less vivacious

manner an ideal object,—this Faculty is the source of errors which I shall comprise in the following paragraph.

¶ XII. Imagination, or the Faculty of Representing with more or less vivacity a recalled object of cognition, is the source of Errors, both when it is too languid and when it is too vigorous. In the former case, the object is respresented obscurely and indistinctly; in the latter, the ideal representation affords the illusive appearance of a sensible presentation.

Par. XII. 4. Imagination,—as a source of Error.

A strong imagination, that is, the power of holding up any ideal object to the mind in clear and steady colors, is a faculty necessary to the poet and to the artist; but not to them alone. It is almost equally requisite for the successful cultivation of every scientific pursuit; and, though differently applied, and different in the character of its representation, it may well be doubted whether Aristotle did not possess as powerful an imagination as Homer. The vigor and perfection of this faculty is seen, not so much in the representation of individual objects and fragmentary sciences, as in the representation of systems. In the better ages of antiquity the perfection, the beauty, of all works of taste, whether in Poetry, Eloquence, Sculpture, Painting, or Music, was principally estimated from the symmetry or proportion of all the parts to each other, and to the whole which they together constituted; and it was only in subservience to this general harmony that the beauty of the several parts was appreciated. In the criticism of modern times, on the contrary, the reverse is true; and we are disposed to look more to the obtrusive

Explication. Necessity of Imagination in scientific pursuits.

Diverse characteristics of art in ancient and modern times.

qualities of details, than to the keeping and unison of a whole. Our works of art are, in general, like kinds of assorted patch-work;—not systems of parts all subdued in conformity to one ideal totality, but coördinations of independent fragments, among which a "*purpureus pannus*" seldom comes amiss. The reason of this difference in taste seems to be, what at first sight may seem the reverse, that in antiquity not the Reason but the Imagination was the more vigorous;—that the Imagination was able to represent simultaneously a more comprehensive system; and thus the several parts being regarded and valued only as conducive to the general result,—these parts never obtained that individual importance, which would have fallen to them had they been only created and only considered for themselves. Now this power of representing to the mind a complex system in all its bearings, is not less requisite to the philosopher than to the poet, though the representation be different in kind; and the nature of the philosophic representations, as not concrete and palpable like the poetical, supposes a more arduous operation, and, therefore, even a more vigorous faculty. But Imagination, in the one case and in the other, requires in proportion to its own power a powerful intellect; for imagination is not poetry nor philosophy, but only the condition of the one and of the other.

But to speak now of the Errors which arise from the disproportion between the Imagination and the Judgment; they originate either in the weakness, or in the inordinate strength, of the former.

Errors which arise from the disproportion between Imagination and Judgment.

Those arising from the weakness of Imagination.

In regard to the errors which arise from the imbecility of the Representative Faculty, it is not difficult to conceive how this imbecility

may become a cause of erroneous judgment. The Elaborative Faculty, in order to judge, requires an object, —requires certain differences to be given. Now, if the imagination be weak and languid, the objects represented by it will be given in such confusion and obscurity, that their differences are either null or evanescent, and judgment thus rendered either impossible, or possible only with the probability of error. In these circumstances, to secure itself from failure, the intellect must not attempt to rise above the actual presentations of sense; it must not attempt any ideal analysis or synthesis,—it must abandon all free and self-active elaboration, and all hope of a successful cultivation of knowledge.

From its disproportionate vivacity.

Again, in regard to the opposite errors, those arising from the disproportioned vivacity of imagination, —these are equally apparent. In this case the renewed or newly-modified representations make an equal impression on the mind as the original presentations, and are, consequently, liable to be mistaken for these. Even during the perception of real objects, a too lively imagination mingles itself with the observation, which it thus corrupts and falsifies. Thus arises what is logically called the *vitium subreptionis*. This is frequently seen in those pretended observations made by theorists in support of their hypotheses, in which, if even the possibility be left for imagination to interfere, imagination is sure to fill up all that the senses may leave vacant. In this case the observers are at once dupes and deceivers, in the words of Tacitus, "*Fingunt simul creduntque.*"

In regard to the remedies for these defects of the Representative Faculty;—in the former case, the only alleviation that can be proposed for a feeble imagination, is to

animate it by the contemplation and study of those works of art which are the products of a strong Phantasy, and which tend to awaken in the student a corresponding energy of that faculty. On the other hand, a too powerful imagination is to be quelled and regulated by abstract thinking, and the study of philosophical, perhaps of mathematical, science.

Remedies for these defects of the Imagination.

The faculty which next follows, is the Elaborative Faculty, Comparison, or the Faculty of Relations. This is the Understanding, in its three functions of Conception, Judgment, and Reasoning. On this faculty take the following paragraph.

¶ XIII. The Affections and the Lower Cognitive Faculties afford the sources and occasions of error; but it is the Elaborative Faculty, Understanding, Comparison, or Judgment, which truly errs. This faculty does not, however, err from strength or over-activity, but from inaction; and this inaction arises either from natural weakness, from want of exercise, or from the impotence of attention.

Par. XIII. 5. Elaborative Faculty,—as a source of Error.

I formerly observed that error does not lie in the conditions of our higher faculties themselves, and that these faculties are not, by their own laws, determined to false judgments or conclusions:

Explication.

Error does not lie in the conditions of our Higher Faculties, but is possible in the application of the laws of those faculties to determinate cases.

"*Nam neque decipitur ratio, nec decipit unquam.*"

If these were otherwise, all knowledge would be impossible,—the root of our nature would be a lie. "But in the application of the laws

of our higher faculties to determinate cases, many errors are possible; and these errors may actually be occasioned by a variety of circumstances. Thus, it is a law of our intelligence, that no event, no phenomenon, can be thought as absolutely beginning to be; we cannot but think that all its constituent elements had a virtual existence prior to their concurrence, to necessitate its manifestation to us; we are thus unable to accord to it more than a relative commencement, in other words, we are constrained to look upon it as the effect of antecedent causes. Now though the law itself of our intelligence—that a cause there is for every event—be altogether exempt from error, yet in the application of this law to individual cases, that is, in the attribution of determinate causes to determinate effects, we are easily liable to go wrong. For we do not know, except from experience and induction, what particular antecedents are the causes of particular consequents; and if our knowledge of this relation be imperfectly generalized, or if we extend it by a false analogy to cases not included within our observation, error is the inevitable consequence. But in all this there is no fault, no failure, of intelligence, there is only a deficiency,—a deficiency in the activity of intelligence, while the Will determines us to a decision before the Understanding has become fully conscious of certainty. The defective action of the Understanding may arise from three causes. In the first place, the Faculty of Judgment may by nature be too feeble. This is the case in idiots and weak persons. In the second place, though not by nature incompetent to judge, the intellect may be without the necessary experience,—may not possess the grounds on which a correct

Defective action of the Understanding may arise from three causes.

(*a*) Natural feebleness. (*b*) Want of necessary experience. (*c*) Incompetency of attention.

judgment must be founded. In the third place,—and this is the most frequent cause of error,—the failure of the understanding is from the incompetency of that act of will which is called *Attention*. Attention is the voluntary direction of the mind upon an object, with the intention of fully apprehending it. The cognitive energy is thus, as it were, concentrated upon a single point. We, therefore, say that the mind collects itself, when it begins to be attentive; on the contrary, that it is distracted, when its attention is not turned upon an object as it ought to be. This fixing—this concentration, of the mind upon an object can only be carried to a certain degree, and continued for a certain time. This degree and this continuance are both dependent upon bodily circumstances; and they are also frequently interrupted or suspended by the intrusion of certain collateral objects, which are forced upon the mind, either from without, by a strong and sudden impression upon the senses, or from within, through the influence of Association; and these, when once obtruded, gradually or at once divert the attention from the original and principal object. If we are not sufficiently attentive, or if the effort which accompanies the concentration of the mind upon a single object be irksome, there arises hurry and thoughtlessness in judging, inasmuch as we judge either before we have fully sought out the grounds on which our decision ought to proceed, or have competently examined their validity and effect. It is hence manifest that a multitude of errors is the inevitable consequence.

In regard to the Regulative Faculty,—Common Sense,—Intelligence,—νοῦς,—this is not in itself a source of error. Errors may, however, arise either from overlooking the laws or necessary principles which it does contain; or by attributing to it, as necessary and original data, what are

only contingent generalizations from experience, and, consequently, make no part of its complement of native truths. But these errors, it is evident, are not to be attributed to the Regulating Faculty itself, which is only a place or source of principles, but to the imperfect operations of the Understanding and Self-consciousness, in not properly observing and sifting the phenomena which it reveals.

6. Regulative Faculty,—not properly a source of Error.

Besides these sources of Error, which immediately originate in the several powers and faculties of mind, there are others of a remoter origin arising from the different habits which are determined by the differences of sex, of age, of bodily constitution, of education, of rank, of fortune, of profession, of intellectual pursuit. Of these, however, it is impossible at present to attempt an analysis; and I shall only endeavor to afford you a few specimens, and to refer you for information in regard to the others to the best sources.

Remote sources of Error in the different habits determinated by sex, age, bodily constitution, education, etc.

Intellectual pursuits or favorite studies, inasmuch as these determine the mind to a one-sided cultivation, that is, to the neglect of some, and to the disproportioned development of other, of its faculties, are among the most remarkable causes of error. This partial or one-sided cultivation is exemplified in three different phases. The first of these is shown in the exclusive cultivation of the powers of Observation, to the neglect of the higher faculties of the Understanding. Of this type are your men of physical science. In this department of

Selected examples of these.

A one-sided cultivation of the intellectual powers.

This exemplified in three different phases. Exclusive cultivation. 1. Of the powers of Observation.

knowledge there is chiefly demanded a patient habit of attention to details, in order to detect phenomena, and, these discovered, their generalization is usually so easy that there is little exercise afforded to the higher energies of Judgment and Reasoning. It was Bacon's boast, that Induction, as applied to nature, would equalize all talents, level the aristocracy of genius, accomplish marvels by coöperation and method, and leave little to be done by the force of individual intellects. This boast has been fulfilled. Science has, by the Inductive Process, been brought down to minds, who previously would have been incompetent for its cultivation, and physical knowledge now usefully occupies many who would otherwise have been without any rational pursuit. But the exclusive devotion to such studies, if not combined with higher and graver speculations, tends to wean the student from the more vigorous efforts of mind, which, though unamusing and even irksome at the commencement, tend, however, to invigorate his nobler powers, and to prepare him for the final fruition of the highest happiness of his intellectual nature.

2. Of Metaphysics.
3. Of Mathematics.
Stewart referred to.

A partial cultivation of the intellect, opposite to this, is given in the exclusive cultivation of Metaphysics and of Mathematics. On this subject I may refer you to some observations of Mr. Stewart, in two chapters entitled *The Metaphysician*, and *The Mathematician*, in the third volume of his *Elements of the Philosophy of the Human Mind*,—chapters distinguished equally by their candor and their depth of observation. On this subject Mr. Stewart's authority is of the highest, inasmuch as he was distinguished in both the departments of knowledge, the tendency of which he so well develops.

LECTURE V.—MODIFIED STOICHEIOLOGY.

SECTION II.—ERROR—ITS CAUSES AND REMEDIES.

C.—LANGUAGE.—D.—OBJECTS OF KNOWLEDGE.

In my last Lecture, I concluded the survey of the Errors which have their origin in the conditions and circumstances of the several Cognitive Faculties, and now proceed to that source of false judgment which lies in the imperfection of the Instrument of thought and Communication,—I mean Language.

III. Language,—as a source of Error.

Much controversy has arisen in regard to the question,—Has man invented Language? But the differences of opinion have in a great measure arisen from the ambiguity or complexity of the terms, in which the problem has been stated. By *language* we may mean either the power which man possesses of associating his thought with signs, or the particular systems of signs with which different portions of mankind have actually so associated their thoughts.

Has man invented Language? Ambiguity of the question.

Taking *language* in the former sense, it is a natural faculty, an original tendency of mind, and, in this view, man has no more invented language than he has invented thought. In fact, the power of thought and the power of language are equally entitled to be considered as elementary qualities of intelligence; for while they are so different that they cannot be identified, they are still so reciprocally necessary that the one cannot exist without the other. It is true, indeed, that presentations and representations of given individual objects might have taken place, although there were no signs with which they were mentally connected, and by which they could be overtly expressed; but all complex and factitious constructions out of these given individual objects, in other words, all notions, concepts, general ideas, or thoughts proper, would have been impossible without an association to certain signs, by which their scattered elements might be combined in unity, and their vague and evanescent existence obtain a kind of definite and fixed and palpable reality. Speech and cogitation are thus the relative conditions of each other's activity, and both concur to the accomplishment of the same joint result. The Faculty of Thinking—the Faculty of forming General Notions—being given, this necessarily tends to energy, but the energy of thinking depends upon the coäctivity of the Faculty of Speech, which itself tends equally to energy. These faculties,—these tendencies,—these energies, thus coëxist and have alway coëxisted; and the result of their combined action is thought in language, and language in thought. So much for the origin of Language, considered in general as a faculty.

In what sense Language is natural to man.

But, though the Faculty of Speech be natural and necessary, that its manifestations are, to a certain extent, contingent and artificial, is evident from the simple fact, that there are more than a single language actually spoken. It may, therefore, be asked—Was the first language, actually spoken, the invention of man, or an inspiration of the Deity? The latter hypothesis cuts, but does not loose the knot. It declares that ordinary causes and the laws of nature are insufficient to explain the phenomenon, but it does not prove this insufficiency; it thus violates the rule of Parcimony, by postulating a second and hypothetical cause to explain an effect, which it is not shown cannot be accounted for without this violent assumption. The first and greatest difficulty in the question is thus:—It is necessary to think in order to invent a language, and the invention of a language is necessary in order to think; for we cannot think without notions, and notions are only fixed by words. This can only be solved, as I have said, by the natural attraction between thought and speech,—by their secret affinity, which is such that they suggest and, *pari passu*, accompany each other. And in regard to the question,—Why, if speech be a natural faculty, it does not manifest itself like other natural principles in a uniform manner,—it may be answered that the Faculty of Speech is controlled and modified in its exercise by external circumstances, in consequence of which, though its exertion be natural and necessary, and, therefore, identical in all men, the special forms of its exertion are in a great degree, con-

Was the first language, actually spoken, the invention of man, or an inspiration of the Deity?

The latter hypothesis considered.

Difficulty of the question.

ventional and contingent, and, therefore, different among different portions of mankind.

Language has a general and a special character.

Considered on one side, languages are the results of our intelligence and its immutable laws. In consequence of this, they exhibit in their progress and development resemblances and common characters which allow us to compare and to recall them to certain primitive and essential forms,—to evolve a system of Universal Grammar. Considered on another side, each language is the offspring of particular wants, of special circumstances, physical and moral, and of chance. Hence it is that every language has particular forms as it has peculiar words. Language thus bears the impress of human intelligence only in its general outlines. There is, therefore, to be found reason and philosophy in all languages, but we should be wrong in believing that reason and philosophy have, in any language, determined everything. No tongue, how perfect soever it may appear, is a complete and perfect instrument of human thought. From its very conditions every language must be imperfect. The human memory can only compass a limited complement of words, but the data of sense, and still more the combinations of the understanding, are wholly unlimited in number. No language can, therefore, be adequate to the ends for which it exists; all are imperfect, but some are far less incompetent instruments than others.

No language is a perfect instrument of thought.

From what has now been said, you will be prepared to find in Language one of the principal sources of Error; but before I go on to consider the particular modes in which the Imperfections of Language are the causes of false

judgments,—I shall comprise the general doctrine in the following paragraph:

Par. XIV. Language,—as a source of Error.

¶ XIV. As the human mind necessarily requires the aid of signs to elaborate, to fix, and to communicate its notions, and as Articulate Sounds are the species of signs which most effectually afford this aid, Speech is, therefore, an indispensable instrument in the higher functions of thought and knowledge. But as speech is a necessary, but not a perfect, instrument, its imperfection must reäct upon the mind. For the Multitude of Languages, the Difficulty of their Acquisition, their necessary Inadequacy, and the consequent Ambiguity of Words, both singly and in combination,—these are all copious sources of Illusion and Error.

Explication. Signs necessary for the internal operation of Thought.

We have already sufficiently considered the reason why thought is dependent upon some system of signs or symbols both for its internal perfection and external expression. The analyses and syntheses,—the decompositions and compositions,—in a word, the elaborations, performed by the Understanding upon the objects presented by External Perception and Self-Consciousness, and represented by Imagination,—these operations are faint and fugitive, and would have no existence, even for the conscious mind, beyond the moment of present consciousness, were we not able to connect, to ratify, and to fix them, by giving to their parts (which would otherwise immediately fall asunder) a permanent unity, by associating them with a sensible symbol, which we may always recall at pleasure, and which, when recalled, recalls along with it the

characters which concur in constituting a notion or factitious object of intelligence. So far signs are necessary for the internal operation of thought itself. But for the communication of thought from one mind to another, signs are equally indispensable. For in itself thought is known,—thought it is knowable, only to the thinking mind itself; and were we not enabled to connect certain complements of thought to certain sensible symbols, and by their means to suggest in other minds those complements of thought of which we were conscious in ourselves, we should never be able to communicate to others what engaged our interest, and man would remain for man, if an intelligence at all, a mere isolated intelligence.

And for the communication of Thought.

In regard to the question,—What may these sensible symbols be, by which we are to compass such memorable effects,—it is needless to show that mien and gesture, which, to a certain extent, afford a kind of natural expression, are altogether inadequate to the double purpose of thought and communication, which it is here required to accomplish. This double purpose can be effected only by symbols, which express, through intonations of the voice, what is passing in the mind. These vocal intonations are either inarticulate or articulate. The former are mere sounds or cries; and, as such, an expression of the feelings of which the lower animals are also capable. The latter constitute words, and these, as the expression of thoughts or notions, constitute Language Proper or Speech. Speech, as we have said, as the instrument of elaborating, fixing, and communicating our

Intonations of the voice the only adequate sensible symbols of thought and its communication.

These inarticulate and articulate.

The latter constitute Language Proper.

How Language is a source of Error.

thoughts, is a principal mean of knowledge, and even the indispensable condition on which depends the exercise of our higher cognitive faculties. But, at the same time, in consequence of this very dependence of thought upon language, inasmuch as language is itself not perfect, the understanding is not only restrained in its operations, and its higher development, consequently, checked, but many occasions are given of positive error. For, to say nothing of the impediment presented to the free communication of thought by the multitude of tongues into which human language is divided, in consequence of which all speech beyond their mother-tongue is incomprehensible to those who do not make a study of other languages,—even the accurate learning of a single language is attended with such difficulties, that perhaps there never yet has been an individual who was thoroughly acquainted with all the words and modes of verbal combination in any single language,—his mother-tongue even not excepted. But the circumstance of principal importance is, that how copious and expressive soever it may be, no language is competent adequately to denote all possible notions, and all possible relations of notions, and from this necessary poverty of language in all its different degrees, a certain inevitable ambiguity arises, both in the employment of single words and of words in mutual connection.

The ambiguity of words the principal source of error originating in Language.

As this is the principal source of the error originating in Language, it will be proper to be a little more explicit. And here it is expedient to take into account two circumstances, which mutually affect each other. The first is, that as the vocabulary of every language is neces-

Two circumstances under this head, which mutually affect each other.

sarily finite, it is necessarily disproportioned to the multiplicity, not to say infinity, of thought; and the second, that the complement of words in any given language has been always filled up with terms significant of objects and relations of the external world, before the want was experienced of words to express the objects and relations of the internal.

The vocabulary of every language necessarily finite. Consequences of this.

From the first of these circumstances, considered exclusively and by itself, it is manifest that one of two alternatives must take place. Either the words of a language must each designate only a single notion,—a single fasciculus of thought,—the multitude of notions not designated being allowed to perish, never obtaining more than a momentary existence in the mind of the individual; or the words of a language must each be employed to denote a plurality of concepts. In the former case, a small amount of thought would be expressed, but that precisely and without ambiguity; in the latter, a large amount of thought would be expressed, but that vaguely and equivocally. Of these alternatives (each of which has thus its advantages and disadvantages), the latter is the one which has universally been preferred; and, accordingly, all languages by the same word express a multitude of thoughts, more or less differing from each other. Now, what is the consequence of this? It is plain that if a word has more than a single meaning attached to it, when it is employed it cannot of itself directly and peremptorily suggest any definite thought;—all that it can do is vaguely and hypothetically to suggest a variety of different notions; and we are obliged from the consideration of the context,—of the tenor,—of the general analogy, of the discourse, to surmise,

with greater or less assurance, with greater or less precision, what particular bundle of characters it was intended to convey. Words, in fact, as languages are constituted, do nothing more than suggest, are nothing more than hints; hints, likewise, which leave the principal part of the process of interpretation to be performed by the mind of the hearer. In this respect, the effect of words resembles the effect of an outline or shade of a countenance with which we are familiar. In both cases, the mind is stimulated to fill up what is only hinted or pointed at. Thus it is that the function of language is not so much to infuse knowledge from one intelligence to another, as to bring two minds into the same train of thinking, and to confine them to the same track. In this procedure what is chiefly wonderful, is the rapidity with which the mind compares the word with its correlations, and in general, without the slightest effort, decides which among its various meanings is the one which it is here intended to convey. But how marvellous soever be the ease and velocity of this process of selection, it cannot always be performed with equal certainty. Words are often employed with a plurality of meanings; several of which may quadrate, or be supposed to quadrate, with the general tenor of the discourse. Error is thus possible; and it is also probable, if we have any prepossession in favor of one interpretation rather than of another. So copious a source of error is the ambiguity of language, that a very large proportion of human controversy has been concerning the sense in which certain terms should be understood; and many disputes have even been fiercely waged, in consequence of the disputants being unaware that they agreed in opinion, and only differed in the meaning they attached

Words are merely hints to the mind.

to the words in which that opinion was expressed. On this subject I may refer you to the very amusing and very instructive treatise of Werenfelsius, entitled *De Logomachiis Eruditorum.*

Remedy for error arising from Language.

In regard to a remedy for this description of error,—this lies exclusively in a thorough study of the language employed in the communication of knowledge, and in an acquaintance with the rules of Criticism and Interpretation. The study of languages, when rationally pursued, is not so unimportant as many fondly conceive; for misconceptions most frequently arise solely from an ignorance of words; and every language may, in a certain sort, be viewed as a commentary upon Logic, inasmuch as every language, in like manner, mirrors in itself the laws of thought.

In reference to the rules of Criticism and Interpretation, —these especially should be familiar to those who make a study of the writings of ancient authors, as these writings have descended to us often in a very mutilated state, and are composed in languages which are now dead. How many theological errors, for example, have only arisen because the divines were either ignorant of the principles of Criticism and Hermeneutic, or did not properly apply them! Doctrines originating in a corrupted lection, or in a figurative expression, have thus arisen and been keenly defended. Such errors are best combated by philological weapons; for these pull them up along with their roots.

A thorough knowledge of languages in general accustoms the mind not to remain satisfied with the husk, but to penetrate in, even to the kernel. With this knowledge we shall not so easily imagine that we understand a system,

when we only possess the language in which it is expressed; we shall not conceive that we truly reason, when we only employ certain empty words and formulæ; we shall not betray ourselves into unusual and obscure expressions, under which our meaning may be easily mistaken; finally, we shall not dispute with others about words, when we are in fact at one with them in regard to things. So much for the errors which originate in Language.

IV. Source of Error, —the Objects of our Knowledge.

As to the last source of Error which I enumerated,—the Objects themselves of our knowledge,—it is hardly necessary to say anything. It is evident that some matters are obscure and abstruse, while others are clear and palpable; and that, consequently, the probability of error is greater in some studies than it is in others. But as it is impossible to deliver any special rules for these cases, different from those which are given for the Acquisition of Knowledge in general, concerning which we are soon to speak,—this source of error may be, therefore, passed over in silence.

We have now thus finished the consideration of the various Sources of Error, and—

Par. XV. Rules touching the Causes and Remedies of our False Judgments.

¶ XV. The following rules may be given, as the results of the foregoing discussion, touching the Causes and Remedies of our False Judgments.

1°, Endeavor as far as possible to obtain a clear and thorough insight into the laws of the Understanding, and of the Mental Faculties in general. Study Logic and Psychology.

2°, Assiduously exercise your mind in the application of these laws. Learn to think methodically.

3°, Concentrate your attention in the act of Thinking; and principally employ the seasons when the Intellect is alert, the Passions slumbering, and no external causes of distraction at work.

4°, Carefully eliminate all foreign interests from the objects of your enquiry, and allow yourselves to be actuated by the interest of Truth alone.

5°, Contrast your various convictions, your past and present judgments, with each other; and admit no conclusion as certain, until it has been once and again thoroughly examined, and its correctness ascertained.

6°, Collate your own persuasions with those of others; attentively listen to and weigh, without prepossession, the judgments formed by others of the opinions which you yourselves maintain.

LECTURE VI.—MODIFIED METHODOLOGY.

SECTION I.—OF THE ACQUISITION OF KNOWLEDGE.

I. EXPERIENCE.—A. PERSONAL:—OBSERVATION—INDUCTION AND ANALOGY.

Means by which our knowledge obtains the character of Perfection, viz., the Acquisition and the Communication of Knowledge.

In our last Lecture, having concluded the Second Department of Concrete Logic,—that which treats of the Causes of Error, we now enter upon the Third part of Concrete or Modified Logic,—that which considers the Means by which our Knowledge obtains the character of Perfection. These means may, in general, be regarded as two,—the Acquisition and the Communication of knowledge,—and these two means we shall, accordingly, consider consecutively and apart.

The acquisition of Knowledge.

In regard to the Acquisition of Knowledge,—we must consider this by reference to the different kinds of knowledge of which the human intellect is capable. And this, viewed in its greatest universality, is of two species.

Human Knowledge of two kinds.

Human knowledge, I say, viewed in its greatest universality, is of two kinds. For either it is one of which the objects are given as contingent phænomena, or one in which the objects are given as necessary facts or laws. In the former

case, the cognitions are called *empirical, experiential*, or *of experience ;* in the latter, *pure, intuitive, rational*, or *of reason*, also *of common sense.* These two kinds of knowledge are, likewise, severally denominated *cognitions a posteriori* and *cognitions a priori.* The distinction of these two species of cognitions consists properly in this,—that the former are solely derived from the Presentations of Sense, External and Internal ; whereas the latter, though first manifested on the occasion of such Presentations, are not, however, mere products of Sense ; on the contrary, they are laws, principles, forms, notions, or by whatever name they may be called, native and original to the mind, that is, founded in, or constituting the very nature of, Intelligence ; and, accordingly, out of the mind itself they must be developed, and not sought for and acquired as foreign and accidental acquisitions. As the Presentative Faculties inform us only of what exists and what happens, that is, only of facts and events,—such empirical knowledge constitutes no necessary and universal judgment ; all, in this case, is contingent and particular, for even our generalized knowledge has only a relative and precarious universality. The cognitions, on the other hand, which are given as Laws of Mind, are, at once and in themselves, universal and necessary. We cannot but think them, if we think at all. The doctrine, therefore, of the Acquisition of Knowledge, must consist of two parts,—the first treating of the acquisition of knowledge through the data of experience, the second, of the acquisition of knowledge through the data of Intelligence.

Doctrine of the Acquisition of Knowledge consists of two parts.

I. The doctrine of Experience. Experience of two kinds,

In regard to the first of these sources, viz., Experience,—this is either our own experience or the experience of others, and in either case it is for us a mean of knowledge. It is manifest that the knowledge we acquire through our personal experience, is far superior in degree to that which we obtain through the experience of other men; inasmuch as our knowledge of an object, in the former case, is far clearer and more distinct, far more complete and lively, than in the latter; while at the same time the latter also affords us a far inferior conviction of the correctness and certainty of the cognition than the former. On the other hand, foreign is far superior to our proper experience in this,—that it is much more comprehensive, and that, without this, man would be deprived of those branches of knowledge which are to him of the most indispensable importance. Now, as the principal distinction of experience is thus into our own experience and into the experience of others, we must consider it more closely in this two-fold relation. First, then, of our Personal Experience.

1. Personal Experience.

Experience necessarily supposes, as its primary condition, certain presentations by the faculties of External or of Internal Perception, and is, therefore, of two kinds, according as it is conversant about the objects of the one of these faculties, or the objects of the other. But the presentation of a fact of the external or of the internal world is not at once an experience. To this there is required a continued series of such presentations, a comparison of these together, a mental separation of the different, a mental combination of the similar, and it, therefore, over and above the operation of the Presenta-

tive Faculties, requires the coöperation of the Retentive, the Reproductive, the Representative, and the Elaborative Faculties. In regard to Experience, as the first means by which we acquire knowledge through the legitimate use and application of our Cognitive Faculties, I give you the following paragraph:

¶ XVI. The First Mean towards the Acquisition of Knowledge is *Experience* (*experientia*, ἐμπειρία). Experience may be, rudely and generally, described as the apprehension of the phænomena of the outer world, presented by the Faculty of External Perception, and of the phænomena of the inner world, presented by the Faculty of Self-consciousness;—these phænomena being retained in Memory, ready for Reproduction and Representation, being also arranged into order by the Understanding.

Par. XVI. Experience; what,—in general.

This paragraph, you will remark, affords only a preliminary view of the general conditions of Experience. In the first place, it is evident, that without the Presentative, or, as they may with equal propriety be called, the Acquisitive, Faculties of Perception, External and Internal, no experience would be possible. But these faculties, though affording the fundamental condition of knowledge, do not of themselves make up experience. There is, moreover, required of the phænomena or appearances the accumulation and retention, the reproduction and representation. Memory, Reminiscence, and Imagination must, therefore, also coöperate. Finally, unless the phænomena be compared together, and be arranged into classes, according to their similarities and differences, it is evident that no judgments,—no conclusions,

Explication.

can be formed concerning them; but without a judgment knowledge is impossible; and as experience is a knowledge, consequently experience is impossible. The Understanding or Elaborative Faculty must, therefore, likewise coöperate. Manilius has well expressed the nature of experience in the following lines.

> "*Per varios usus artem experientia fecit,*
> *Exemplo monstrante viam.*"

And Afranius in the others:

> "*Usus me genuit, mater peperit Memoria;*
> *Sophiam vocant me Graii, vos Sapientiam.*"

Common and Scientific Experience.

Our own observation, be it external or internal, is either with, or without, intention; and it consists either of a series of Presentations alone, or Abstraction and Reflection supervene, so that the presentations obtain that completion and system which they do not of themselves possess. In the former case, the experience may be called an *Unlearned* or *Common;* in the latter, a *Learned* or *Scientific Experience.* Intentional and reflective experience is called *Observation.*

Observation—what. Of two kinds,—Observation Proper, and Experiment.

Observation is of two kinds; for either the objects which it considers remain unchanged, or, previous to its application, they are made to undergo certain arbitrary changes, or are placed in certain factitious relations. In the latter case, the observation contains the specific name of *Experiment.* Observation and experiment do not, therefore, constitute opposite or two different procedures,—the latter is, in propriety, only a certain subordinate modification of the former; for, while observation may accomplish its end without experiment, ex-

periment without observation is impossible. Observation and experiment are manifestly exclusively competent upon the objects of our empirical knowledge; and they coöperate, equally and in like manner, to the progress of that knowledge, partly by establishing, partly by correcting, partly by amplifying it. Under observation, therefore, is not to be understood a common or unlearned experience, which obtrudes itself upon every one endowed with the ordinary faculties of Sense and Understanding, but an intentional and continued application of the faculties of Perception, combined with an abstractive and reflective attention to an object or class of objects, a more accurate knowledge of which, it is proposed, by the observation, to accomplish. But in order that the observation should accomplish this end,—more especially when the objects are numerous and a systematic complement of cognitions is the end proposed,—

Præcognita of Observation.

it is necessary that we should know certain præcognita,—1°, What we ought to observe; 2°, How we ought to observe; and 3°, By what means are the data of observation to be reduced to system. The first of these concerns the Object; the second, the Procedure; the third, the scientific Completion of the observations. It is proper to make some general observations in regard to these, in their order; and first, of the Object of observation,—the *what* we ought to observe.

First,—The Object of Observation. This fourfold.

The Object of Observation can only be some given and determined phænomenon, and this phænomenon either an external or an internal. Through observation, whether external or internal, there are four several cognitions which we propose to compass, viz., to ascertain—1°, What

the Phænomena themselves are; 2°, What are the Conditions of their Reality; 3°, What are the Causes of their Existence; 4°, What is the Order of their Consecution.

1°, What the Phænomena are.

In regard to what the phænomena themselves are *(quid sint)*, that is, in regard to what constitutes their peculiar nature,—this, it is evident, must be the primary matter of consideration, it being always supposed that the fact (the *an sit)* of the phænomenon itself has been established. To this there is required, above all, a clear and distinct Presentation or Representation of the object. In order to obtain this, it behooves us to analyze,—to dismember,—the constituent parts of the object, and to take into proximate account those characters which constitute the object, that is, which make it to be what it is, and nothing but what it is. This being performed, we must proceed to compare it with other objects, and with those especially which bear to it the strongest similarity, taking accurate note always of those points in which they reciprocally resemble and in which they reciprocally disagree.

In their individual peculiarities and contrasts.

As under determinate genera and species.

But it is not enough to consider the several phænomena in their individual peculiarities and contrasts,—in what they are, and in what they are not,—it is also requisite to bring them under determinate genera and species. To this end we must, having obtained (as previously prescribed) a clear and distinct knowledge of the several phænomena in their essential similarities and differences, look away or abstract from the latter,—the differences, and comprehend the former,—the similarities, in a compendious and characteristic notion, under an appropriate name.

When the distinctive peculiarities of the phænomena have been thus definitely recognized, the second question emerges,—What are the Conditions of their Reality. These conditions are commonly called *Requisites*, and under *requisite* we must understand all that must have preceded, before the phænomena could follow. In order to discover the requisites, we take a number of analogous cases, or cases similar in kind, and inquire what are the circumstances under which the phænomena always arises, if it does arise, and what are the circumstances under which it never arises; and then, after a competent observation of individual cases, we construct the general judgment, that the phænomenon never occurs unless this or that other phænomenon has preceded, or at least accompanied, it. Here, however, it must be noticed, that nothing can be viewed as a requisite which admits of any, even the smallest, exception.

2°, What the Conditions of their Reality.

The requisite conditions being discovered, the third question arises,—What are the Causes of the Phænomena. According to the current doctrine, the *causes* of phænomena are not to be confounded with their *requisites;* for although a phænomenon no more occurs without its requisite than without its cause, still, the requisite being given, the phænomenon does not necessarily follow, and, indeed, very frequently does not ensue. On the contrary, if the cause occurs, the phænomenon must occur also. In other words, the requisite or condition is that without which the phænomenon never is; the cause, on the other hand, is that through which it always is. Thus an emotion of pity never arises without a knowledge of the misfortune of another; but so little does this knowledge necessitate that emotion,

3°, What the Causes of the Phænomena.

that its opposite, a feeling of rejoicing, complacency, at such suffering may ensue; whereas the knowledge of another's misfortune must be followed by a sentiment of pity, if we are predisposed in favor of the person to whom the misfortune has occurred. In this view, the knowledge of another's misfortune is only a requisite; whereas our favorable predisposition constitutes the cause. It must, however, be admitted, that in different relations one and the same circumstance may be both requisite and cause; and, in point of fact, it would be more correct to consider the cause as the whole sum of antecedents, without which the phænomenon never does take place, and with which it always must. What are commonly called *requisites*, are thus, in truth, only partial causes; what are called *causes*, only proximate requisites.

4°, What the Order of their Consecution.

In the fourth place, having ascertained the essential qualities,—the Conditions and the Causes of phænomena,—a final question emerges,—What is the Order in which they are manifested? and this being ascertained, the observation has accomplished its end. This question applies either to a phænomenon considered in itself, or to a phænomenon considered in relation to others. In relation to itself, the question concerns only the time of its origin, of its continuance, and of its termination; in relation to others, it concerns the reciprocal consecution in which the several phænomena appear.

Second,—The Manner of Observation.

We now go on to the second Præcognitum,—the Manner of Observation,—How we are to observe. What we have hitherto spoken of—the Object—can be known only in one way,—the way of Scientific Observation. It therefore remains to

be asked,—How must the observation be instituted, so as to afford us a satisfactory result in regard to all the four sides on which it behooves an object to be observed? In the first place, as preliminary to observation, it is required that the observing mind be tranquil and composed, be exempt from prejudice, partiality, and prepossession, and be actuated by no other interest than the discovery of truth. Tranquility and composure of mind are of peculiar importance in our observation of the phænomena of the internal world; for these phænomena are not, like those of the external, perceptible by sense, enclosed in space, continuous and divisible; and they follow each other in such numbers, and with such a rapidity, that they are at best observable with difficulty, often losing even their existence by the interference of the observing,—the reflective energy, itself. But that the observation should be always conducted in the calm and collected state of mind required to purify this condition, we must be careful to obtain, more and more, a mastery over the Attention, so as to turn it with full force upon a single aspect of the phænomena, and, consequently, to abstract it altogether from every other. Its proper function is to contemplate the objects of observation tranquilly, continuously, and without anxiety for the result; and this, likewise, without too intense an activity or too vigorous an application of its forces. But the observation and concomitant energy of attention will be without result, unless we previously well consider what precise object or objects we are now to observe. Nor will our experience obtain an answer to the question proposed for it to solve, unless that question be of such a nature as will animate the observing faculties by some stimulus, and give them a

1°, Proper state of the observing mind.

determinate direction. Where this is not the case, attention does not effect anything, nay, it does not operate at all. On this account such psychological questions as the following: What takes place in the process of Self-consciousness,—of Perception,—of Vision,—of Hearing,—of Imagination, etc.,—cannot be answered, as thus absolutely stated, that is, without reference to some determinate object. But if I propose the problem,—What takes place when I see this or that object, or better still, when I see this table,—the attention is stimulated and directed, and even a child can give responses, which, if properly illustrated and explained, will afford a solution to the problem. If, therefore, the question upon the object of observation be too vague and general, so that the attention is not suitably excited and applied,—this question must be divided and subdivided into others more particular, and this process must be continued until we reach a question which affords the requisite conditions. We should, therefore, determine as closely as possible the object itself, and the phases in which we wish to observe it, separate from it all foreign or adventitious parts, resolve every question into its constituent elements, enunciate each of these as specially as possible, and never couch it in vague and general expressions. But here we must at the same time take care that the object be not so torn and mangled that the attention feels no longer any attraction to the several parts, or that the several parts can no longer be viewed in their natural connection. So much it is possible to say in general, touching the Manner in which observation ought to be carried on; what may further be added under this head, depends upon the particular nature of the objects to be observed.

2°, Conditions of the question to be determined by the observation.

In this manner, then, must we proceed, until all has been accomplished which the problem, to be answered by the observation, pointed out. When the observation is concluded, an accurate record or notation of what has been observed is of use, in order to enable us to supply what is found wanting in our subsequent observation. If we have accumulated a considerable apparatus of results, in relation to the object we observe, it is proper to take a survey of these; from what is found defective, new questions must be evolved, and an answer to these sought out through new observations. When the inquiry has attained its issue, a tabular view of all the observations made upon the subject is convenient, to afford a conspectus of the whole, and as an aid to the memory. But how (and this is the Third Precognition) individual observations are to be built up into a systematic whole, is to be sought for partly from the nature of science in general, partly from the nature of the particular empirical science for the constitution of which the observation is applied. Nor is what is thus sought difficult to find. It is at once evident, that a synthetic arrangement is least applicable in the empirical sciences. For, anterior to observation, the object is absolutely unknown; and it is only through observation that it becomes a matter of science. We can, therefore, only go to work in a problematic or interrogative manner, and it is impossible to commence by assertory propositions, of which we afterwards lead the demonstration. We must, therefore, determine the objects on all sides, in so far as observation is competent to this; we must analyze every question into its subordinate questions, and each of these must find its answer in observation. The systematic order is thus given

Third,—The means by which the data of Observation are to be reduced to system.

naturally and of itself; and in this procedure it is impossible that it should not be given. But for a comprehensive and all-sided system of empirical knowledge, it is not sufficient to possess the whole data of observation, to have collected these together, and to have arranged them according to some external principle; it is, likewise, requisite that we have a thorough-going principle of explanation, even though this explanation be impossible in the way of observation, and a power of judging of the data, according to universal laws, although these universal laws may not be discovered by experience alone. These two ends are accomplished by different means. The former we compass by the aid of Hypothesis, the latter, by the aid of Induction and Analogy. Of these in detail. In regard to Hypothesis, I give you the following paragraph.

¶ XVII. When a phænomenon is presented, which can be explained by no principle afforded through Experience, we feel discontented and uneasy; and there arises an effort to discover some cause which may, at least provisorily, account for the outstanding phænomenon; and this cause is finally recognized as valid and true, if, through it, the given phænomenon is found to obtain a full and perfect explanation. The judgment in which a phænomenon is referred to such a problematic cause, is called an *Hypothesis.*

Par. XVII. Hypothesis,—what.

Hypotheses have thus no other end than to satisfy the desire of the mind to reduce the objects of its knowledge to unity and system; and they do this in recalling them, *ad interim,* to some principle, through which the mind is enabled to comprehend them. From this view of their

Explication. Hypothesis,—its end.

nature, it is manifest how far they are permissible, and how far they are even useful and expedient; throwing altogether out of account the possibility, that what is at first assumed as hypothetical, may, subsequently, be proved true.

When our experience has revealed to us a certain correspondence among a number of objects, we are determined, by an original principle of our nature, to suppose the existence of a more extensive correspondence than our observation has already proved, or may ever be able to establish. This tendency to generalize our knowledge by the judgment,—that where much has been found accordant, all will be found accordant,—is not properly a conclusion deduced from premises, but an original principle, of our nature, which we may call that of *Logical*, or perhaps better, that of *Philosophical, Presumption*. This Presumption is of two kinds; it is either Induction or Analogy, which, though usually confounded, are, however, to be carefully distinguished. I shall commence the consideration of these by the following paragraph.

Par. XVIII. Induction and Analogy.

¶ XVIII. If we have uniformly observed that a number of objects of the same class (genus or species) possess in common a certain attribute, we are disposed to conclude that this attribute is possessed by all the objects of that class. This conclusion is properly called an *Inference of Induction*. Again, if we have observed that two or more things agree in several internal and essential characters, we are disposed to conclude that they agree, likewise, in all other essential characters, that is, that they are constituents of the same class (genus or species). This conclusion is properly called an *Inference of Analogy*.

The principle by which, in either case, we are disposed to extend our inferences beyond the limits of experience, is a natural or ultimate principle of intelligence; and may be called the principle of *Logical*, or, more properly, of *Philosophical Presumption.*

Explication. Induction and Analogy, — their agreement and difference.

The reasoning by Induction and the reasoning by Analogy have this in common, that they both conclude from something observed to something not observed; from something within to something beyond the sphere of actual experience. They differ, however, in this, that, in Induction, that which is observed and from which the inference is drawn to that which is not observed, is a unity in plurality; whereas, in Analogy, it is a plurality in unity. In other words, in Induction, we look to the one in the many; in Analogy we look to the many in the one; and while in both we conclude to the unity in totality, we do this, in Induction, from the recognized unity in plurality, in Analogy, from the recognized plurality in unity. Thus, as induction rests upon the principle, that what belongs (or does not belong) to many things of the same kind, belongs, (or does not belong) to all things of the same kind; so analogy rests upon the principle,—that things which have many observed attributes in common, have other not observed attributes in common likewise. It is hardly necessary to remark that we are now speaking of Induction and Analogy, not as principles of Pure Logic, and as necessitated by the fundamental laws of thought, but of these as means of acquiring knowledge, and as legitimated by the conditions of objective reality. In Pure Logic, Analogy has no place, and only that Induction is admitted, in which all the several parts are supposed to

legitimate the inference to the whole. Applied Induction, on the contrary, rests on the constancy,—the uniformity of nature, and on the instinctive expectation we have of this stability. This constitutes what has been called the principle of *Logical Presumption*, though perhaps it might, with greater propriety, be called the principle of *Philosophical Presumption*. We shall now consider these severally; and, first, of Induction.

Induction,—what.

An Induction is the enumeration of the parts, in order to legitimate a judgment in regard to the whole. Now, the parts may either be individuals or particulars, strictly so called. I say strictly so called, for you are aware that the term *particular* is very commonly employed, not only to denote the species, as contained under a genus, but, likewise, to denote the individual, as contained under a species. Using, however, the two terms in their proper significations, I say, if the parts are individual or singular things, the induction is then called *Individual;* whereas if the parts be species or subaltern genera, the induction then obtains the name of *Special*. An example of the Individual Induction is given, were we to argue thus,—*Mercury, Venus, the Earth, Mars, etc., are bodies in themselves opaque, and which borrow their light from the sun. But Mercury, Venus, etc., are planets. Therefore, all planets are opaque, and borrow their light from the sun.* An example of the special is given, were we to argue as follows,—*Quadrupeds, birds, fishes, the amphibia, etc., all have a nervous system. But quadrupeds, birds, etc., are animals. Therefore all animals* (though it is not yet detected in some) *have a nervous system.* Now, here it is manifest that Special rests upon Individual Induction,

Of two kinds,—Individual and Special.

and that, in the last result, all induction is individual. For we can assert nothing concerning species, unless what we assert of them has been previously observed in their constituent singulars.

The two conditions of legitimate Induction,—First.

For a legitimate Induction there are requisite at least two conditions. In the first place, it is necessary, That the partial (and this word I use as including both the terms *individual* and *particular,)*—I say, it is necessary that the partial judgments out of which the total or general judgment is inferred, be all of the same quality. For if one even of the partial judgments had an opposite quality, the whole induction would be subverted. Hence it is that we refute universal judgments founded on an imperfect induction, by bringing what is called an instance *(instantia)*, that is, by adducing a thing belonging to the same class or notion, in reference to which the opposite holds true. For example, the general assertion, *All dogs bark*, is refuted by the instance of the dogs of Labrador or California (I forget which),—these do not bark. In like manner, the general assertion, *No quadruped is oviparous*, is refuted by the instance of the *Ornithorhynchus Paradoxus*. But that the universal judgment must have the same quality as the partial, is self-evident; for this judgment is simply the assertion of something to be true of all which is true of many.

Second.

The second condition required is, That a competent number of the partial objects from which the induction departs, should have been observed, for otherwise the comprehension of other objects under the total judgment would be rash. What is the number of such objects, which amounts to a

competent induction, it is not possible to say in general. In some cases, the observation of a very few particular or individual examples is sufficient to warrant an assertion in regard to the whole class; in others, the total judgment is hardly competent, until our observation has gone through each of its constituent parts. This distinction is founded on the difference of essential and unessential characters. If the character be essential to the several objects, a comparatively limited observation is necessary to legitimate our general conclusion. For example, it would require a far less induction to prove that all animals breathe, than to prove that the mamalia, and the mamalia alone, have lateral lobes to the cerebellum. For the one is seen to be a function necessary to animal life; the other, as far as our present knowledge reaches, appears only as an arbitrary concomitant. The difference of essential and accidental is, however, one itself founded on induction, and varies according to the greater or less perfection to which this has been carried. In the progress of science, the lateral lobes of the cerebellum may appear to future physiologists as necessary a condition of the function of suckling their young, as the organs of breathing appear to us of circulation and of life.

Summary of the doctrine of Induction

To sum up the Doctrine of Induction,—"This is more certain, 1°, In proportion to the number and diversity of the objects observed;—2°, In proportion to the accuracy with which the observation and comparison have been conducted;—3°, In proportion as the agreement of the objects is clear and precise;—and, 4°, In proportion as it has been thoroughly explored, whether there exist exceptions or not."

Almost all induction is, however, necessarily imperfect; and Logic can inculcate nothing more important on the

investigators of nature than that sobriety of mind, which regards all its past observations only as hypothetically true, only as relatively complete, and which, consequently, holds the mind open to every new observation, which may correct and limit its former judgments.

Analogy,—what.

So much for Induction; now for Analogy. Analogy, in general, means proportion, or a similarity of relations. Thus, to judge analogically, or according to analogy, is to judge things by the similarity of their relations. Thus, when we judge that as two is to four, so is eight to sixteen, we judge that they are analogically identical; that is, though the sums in other respects are different, they agree in this, that as two is the half of four, so eight is the half of sixteen.

In common language, however, this propriety of the term is not preserved. For *by analogy* is not always meant merely *by proportion*, but frequently *by comparison—by relation*, or simply *by similarity*. In so far as Analogy constitutes a particular kind of reasoning from the individual or particular to the universal, it signifies an inference from the partial similarity of two or more things to their complete or total similarity. For example, — *This disease corresponds in many symptoms with those we have observed in typhus fevers; it will, therefore, correspond in all, that is, it is a typhus fever.*

Has two essential conditions,—First.

Like Induction, Analogy has two essential requisites. In the first place, it is necessary that of two or more things a certain number of attributes should have observed, in order to ground the inference that they also agree in those other attributes, which it has not yet been ascertained that they possess. It is evident that in proportion to the number of

points observed, in which the things compared together coincide, in the same proportion can it be with safety assumed, that there exists a common principle in these things, on which depends the similarity in the points known as in the points unknown.

Second. In the second place, it is required that the predicates already observed should neither be all negative nor all contingent; but that some at least should be positive and necessary. Mere negative characters denote only what the thing is not; and contingent characters need not be present in the thing at all. In regard to negative attributes, the inference, that two things, to which a number of qualities do not belong, and which are, consequently, similar to each other only in a negative point of view,—that these things are, therefore, absolutely and positively similar, is highly improbable. But that the judgment in reference to the compared things (say A and X) must be of the same quality (*i. e.* either both affirmative or both negative), is self-evident. For if it be said A *is* B, X *is not* B, A *is not* C, X *is* C; their harmony or similarity is subverted, and we should rather be warranted in arguing their discord and dissimilarity in other points. And here it is to be noticed that Analogy differs from Induction in this, that it is not limited to one quality, but that it admits of a mixture of both.

In regard to contingent attributes, it is equally manifest that the analogy cannot proceed exclusively upon them. For, if two things coincide in certain accidental attributes (for example, two men in respect of stature, age, and dress,) the supposition that there is a common principle, and a general similiarity founded thereon, is very unlikely.

Summary of the doctrine of Analogy.

To conclude: Analogy is certain in proportion, 1°, To the number of congruent observations; 2°, To the number of congruent characters observed; 3°, To the importance of these characters and their essentiality to the objects; and, 4°, To the certainty that the characters really belong to the objects, and that a partial correspondence exists. Like Induction, Analogy can only pretend at best to a high degree of probability; it may have a high degree of certainty, but it never reaches to necessity.

Induction and Analogy compared together.

Comparing these two processes together: The Analogical is distinguished from the Inductive in this —that Induction regards a single predicate in many subjects as the attribute Z in A, in B, in C, in D, in E, in F, etc.; and as these many belong to one class, say Q; it is inferred that Z will, likewise, be met with in the other things belonging to this class, that is, in all Qs. On the other hand, Analogy regards many attributes in one subject (say *m*, *n*, *o*, *p*, in A); and as these many are in part found in another subject (say *m*, and *n*, in B), it is concluded that, in that second thing, there will also be found the other attributes (say *o* and *p*). Through Induction we, therefore, endeavor to prove that one character belongs (or does not belong) to all the things of a certain class, because it belongs (or does not belong) to many things of that class. Through Analogy on the other hand, we seek to prove that all the characters of a thing belong (or do not belong) to another or several others, because many of these characters belong to this other or these others. In the one it is proclaimed,—*One in many, therefore one in all.*—In the other it is proclaimed,—*Many in one, therefore all in one.*

By these Processes of Induction and Analogy, as observed, we are unable to attain absolute certainty ;—a great probability is all that we can reach, and this for the simple reason, that it is impossible, under any condition, to infer the unobserved from the observed,—the whole from any proportion of the parts,—in the way of any rational necessity. Even from the requisites of Induction and Analogy, it is manifest that they bear the stamp of uncertainty ; inasmuch as they are unable to determine how many objects or how many characters must be observed, in order to draw the conclusion that the case is the same with all the other objects, or with all the other characters. It is possible only in one way to raise Induction and Analogy from mere probability to complete certainty,—viz., to demonstrate that the principles which lie at the root of these processes, and which we have already stated, are either necessary laws of thought, or necessary laws of nature. To demonstrate that they are necessary laws of thought is impossible ; for Logic not only does not allow inference from many to all, but expressly rejects it. Again, to demonstrate that they are necessary laws of nature is equally impossible. This has indeed been attempted, from the uniformity of nature, but in vain. For it is incompetent to evince the necessity of the inference of Induction and Analogy from the fact denominated *the law of nature ;* seeing that this law itself can only be discovered by the way of Induction and Analogy. In this attempted demonstration there is thus the most glaring *petitio principii.* The result which has been previously given remains, therefore, intact :—Induction and Analogy guarantee no perfect certainty, but only a high degree of probability, while all probability rests at best upon Induction and Analogy, and nothing else.

Induction and Analogy do not afford absolute certainty.

LECTURE VII.—MODIFIED METHODOLOGY.

SECTION I.—OF THE ACQUISITION OF KNOWLEDGE.

I. EXPERIENCE—B. FOREIGN:—ORAL TESTIMONY—ITS CREDIBILITY.

Foreign Experience.

HAVING, in our last Lecture, terminated the Doctrine of Empirical Knowledge, considered as obtained Immediately,—that is, through the exercise of our own powers of Observation,—we are now to enter on the doctrine of Empirical Knowledge considered as obtained Mediately,—that is, through the Experience of Other Men. The following paragraph will afford you a general notion of the nature and kinds of this knowledge.

Par. XIX. Testimony.

¶ XIX. A matter of Observation or Empirical Knowledge can only be obtained Mediately, that is, by one individual from another, through an enouncement declaring it to be true. This enouncement is called, in the most extensive sense of the word, a *Witnessing* or *Testimony (testimonium)*; and the person by whom it is made is, in the same sense, called a *Witness*, or *Testifier (testis)*. The object of the testimony is called the *Fact (factum)*; and its validity constitutes what is styled *Historical Credibility (credibilitas historica)*. To estimate this credibility, it is requisite to consider—

1°, The Subjective Trustworthiness of the Witnesses *(fides testium)*, and 2°, The Objective Probability of the Fact itself. The former is founded partly on the Sincerity, and partly on the Competence, of the Witness. The latter depends on the Absolute and Relative Possibility of the Fact itself. Testimony is either Immediate or Mediate. Immediate, where the fact reported is the object of a Personal Experience; Mediate, where the fact reported is the object of a Foreign Experience.

Explication.

It is manifest that Foreign Experience, or the experience of other men, is astricted to the same laws, and its certainty measured by the same criteria, as the experience we carry through ourselves. But the experience of the individual is limited, when compared with the experience of the species; and if men did not possess the means of communicating to each other the results of their several observations,—were they unable to coöperate in accumulating a stock of knowledge, and in carrying on the progress of discovery,—they would never have risen above the very lowest steps in the acquisition of science. But to this mutual communication they are competent; and each individual is thus able to appropriate to his own benefit the experience of his fellow-men, and to confer on them in return the advantages which his own observations may supply. But it is evident that this reciprocal communication of their respective experiences among men, can only be effected inasmuch as one is able to inform another of what he has himself observed, and that the vehicle of this information can only be some enouncement in conventional signs of one character or another. The enouncement of what has been observed is, as stated in the paragraph, called

a witnessing,—a bearing witness,—a testimony, etc., these terms being employed in their wider acceptation; and he by whom this declaration is made, and on whose veracity it rests, is called a *witness*, *voucher*, or *testifier (testis)*. The term *testimony*, I may notice, is sometimes, by an abusive metonym, employed for *witness;* and the word *evidence* is often ambiguously used for *testimony*, and for the bearer of testimony,—*the witness.*

The proper object of Testimony,

Such an enouncement,—such a testimony, is, however, necessary for others, only when the experience which it communicates is beyond the compass of their own observation. Hence it follows, that matters of reasoning are not proper objects of testimony, since matters of reasoning, as such, neither can rest, nor ought to rest, on the observations of others; for a proof of their certainty is equally competent to all, and may by all be obtained in the manner in which it was originally obtained by those who may bear witness to their truth. And hence it further follows, that matters of experience alone are proper objects of testimony; and of matters of experience themselves, such only as are beyond the sphere of our personal experience. Testimony, in the strictest sense of the term, therefore, is the communication of an experience, or, what amounts to the same thing, the report of an observed phænomenon, made to those whose own experience or observation has not reached so far.

The Fact. Historical credibility.

The object of testimony, as stated in the paragraph, is called the *fact;* the validity of a testimony is called *historical credibility.* The testimony is either immediate or mediate. Immediate when the witness has himself observed the fact to which he testifies; mediate, when the

witness has not himself had experience of this fact, but has received it on the testimony of others. The former, the immediate witness, is commonly styled an *eye-witness (testis oculatus)*; and the latter, the mediate witness, an *ear-witness (testis auritas)*. The superiority of immediate to mediate testimony is expressed by Plautus, "*Pluris est oculatus testis unus, quam auriti decem.*" These denominations, *eye* and *ear witness*, are however, as synonyms of *immediate* and *mediate witness*, not always either applicable or correct. The person on whose testimony a fact is mediately reported, is called the *guarantee*, or he on whose authority it rests; and the guarantee himself may be again either an immediate or a mediate witness. In the latter case he is called a *second-hand* or *intermediate witness*; and his testimony is commonly styled *hearsay evidence*. Further, Testimony, whether immediate or mediate, is either *partial* or *complete*; either *consistent* or *contradictory*. These distinctions require no comment. Finally, testimony is either *direct* or *indirect*; direct, when the witness has no motive but that of making known the fact; indirect, when he is actuated to this by other ends.

Eye-witness. Ear-witness.

The Guarantee.

Testimonies,—Partial, Complete, Consistent, Contradictory.

The only question in reference to Testimony is that which regards its Credibility; and the question concerning the credibility of the witness may be comprehended under that touching the Credibility of Testimony. The order I shall follow in the subsequent observations is this,—I shall, in the first place, consider the Credibility of Testimony in general; and,

Division of the subject: I. Credibility of Testimony in general. II. Credibility of Testimony in its particular forms of Immediate and Mediate.

in the second, consider the Credibility of Testimony in its particular forms of Immediate and Mediate.

First, then, in regard to the Credibility of Testimony in general;—When we inquire whether a certain testimony is, or is not, deserving of credit, there are two things to be considered: 1°, The Object of the Testimony, that is, the fact or facts for the truth of which the Testimony vouches; and, 2°, The Subject of the Testimony, that is, the person or persons by whom the testimony is borne. The question, therefore, concerning the Credibility of testimony, thus naturally subdivides itself into two. Of these questions, the first asks, What are the conditions of the credibility of a testimony by reference to what is testified, that is, in relation to the Object of the testimony? The second asks,—What are the conditions of the credibility of a testimony by him who testifies, that is, in relation to the Subject of the testimony? Of these in their order.

I. Credibility of Testimony in general. 1°, The Object of the Testimony. Its absolute Possibility.

On the first question.—"In regard to the matter testified, that is, in regard to the object of the testimony; it is, first of all, a requisite condition, that what is reported to be true should be possible, both absolutely, or as an object of the Elaborative Faculty, and relatively, or as an object of the Presentative Faculties,—Perception, External or Internal. A thing is possible absolutely, or in itself, when it can be construed to thought, that is, when it is not inconsistent with the logical laws of thinking; a thing is relatively possible as an object of Perception, External or Internal, when it can affect Sense or Self-consciousness, and, through such affection, determine its apprehension by one or other of these faculties. A testimony is, therefore, to be unconditionally rejected, if

the fact which it reports be either in itself impossible, or impossible as an object of the Presentative Faculties. But the impossibility of a thing, as an object of these faculties, must be decided either upon physical, or upon metaphysical, principles. A thing is physically impossible as an object of sense, when the existence itself, or its perception by us, is, by the laws of the material world, impossible. It is metaphysically impossible, when the object itself, or its perception, is possible neither through a natural nor through a supernatural, agency. But, to establish the metaphysical impossibility of a thing, it is not sufficient that its existence cannot be explained by the ordinary laws of nature, or even that its existence should appear repugnant with these laws; it is requisite that an universal and immutable law of nature should have been demonstrated to exist, and that this law would be subverted if the fact in question were admitted to be physically possible. In like manner, to constitute the metaphysical impossibility of a thing, it is by no means enough to show that it is not explicable on natural laws, or even that any natural law stands opposed to it; it is further requisite to prove that the intervention even of supernatural agency is incompetent to its production, that its existence would involve the violation of some necessary principle of reason.

Physical and Metaphysical Impossibility.

To establish the credibility of a testimony, in so far as this is regulated by the nature of its object, there is, besides the proof of the absolute possibility of this object, required also a proof of its relative possibility; that is, there must not only be no contradiction between its necessary attributes,—the attributes by which it must be thought,—but no contra-

Relative Possibility of an object.

diction between the attributes actually assigned to it by the testimony. A testimony, therefore, which, *qua* testimony, is self-contradictory, can lay no claim to credibility; for what is self-contradictory is logically suicidal. And here the only question is,—Does the testimony, *qua* testimony, contradict itself? for if the repugnancy arise from an opinion of the witness, apart from which the testimony as such would still stand undisproved, in that case the testimony is not at once to be repudiated as false. For example, it would be wrong to reject a testimony to the existence of a thing, because the witness had to his evidence of its observed reality annexed some conjecture in regard to its origin or cause. For the latter might well be shown to be absurd, and yet the former would remain unshaken. It is, therefore, always to be observed,—that it is only the self-contradiction of a testimony, *qua* testimony, that is, the self-contradiction of the fact itself, which is peremptorily and irrevocably subversive of its credibility.

We now proceed to the second question; that is, to consider in general the Credibility of a Testimony by reference to its subject, that is, in relation to the Personal Trustworthiness of the Witness. The trustworthiness of a witness consists of two elements or conditions. In the first place, he must be willing, in the second place, he must be able, to report the truth. The first of these elements is the Honesty,—the Sincerity,—the Veracity; the second is the Competency of the Witness. Both are equally necessary, and if one or other be deficient, the testimony becomes altogether null. These constituents, likewise, do not infer each other; for it frequently happens that where the honesty

2°, The Subject of the Testimony, or personal trustworthiness of the Witness. This consists of two elements:—(a) Honesty or Veracity.

is greatest the competency is least, and where the competency is greatest, the honesty is least. But when the veracity of a witness is established, there is established also a presumption of his competency; for an honest man will not bear evidence to a point in regard to which his recollection is not precise, or to the observation of which he had not accorded the requisite attention. In truth, when a fact depends on the testimony of a single witness, the competency of that witness is solely guaranteed by his honesty. In regard to the honesty of a witness,—this, though often admitting of the highest probability, never admits of absolute certainty; for, though in many cases, we may know enough of the general character of the witness to rely with perfect confidence on his veracity, in no case can we look into the heart, and observe the influence which motives have actually had upon his volitions. We are, however, compelled, in many of the most important concerns of our existence, to depend on the testimony, and, consequently, to confide in the sincerity, of others. But from the moral constitution of human nature, we are warranted in presuming on the honesty of a witness; and this presumption is enhanced in proportion as the following circumstances concur in its confirmation. In the first place, a witness is to be presumed veracious in this case, in proportion as his love of truth is already established from others. In the second place, a witness is to be presumed veracious, in proportion as he has fewer and weaker motives to falsify his testimony. In the third place, a witness is to be presumed veracious, in proportion to the likelihood of contradiction which his testimony would encounter, if he

The presumption of the Honesty of a Witness enhanced by certain circumstances.

deviated from the truth. So much for the Sincerity, Honesty, or Veracity of a witness.

(b) Competency of a Witness.

In regard to the Competency or Ability of a witness,—this, in general, depends on the supposition that he has had it in his power correctly to observe the fact to which he testifies, and correctly to report it. The presumption in favor of the competence of a witness rises in proportion as the following conditions are fulfilled:—In the first place, he must be presumed competent in reference to the case in hand, in proportion as his general ability to observe and to communicate his observation has been established in other cases. In the second place, the competency of a witness must be presumed, in proportion as in the particular case a lower and commoner amount of ability is requisite rightly to observe, and rightly to report the observation. In the third place, the competency of a witness is to be presumed, in proportion as it is not to be presumed that his observation was made or communicated at a time when he was unable correctly to make or correctly to communicate it. So much for the Competency of a witness.

Circumstances by which the presumption of competency is enhanced.

The credibility of Testimony not invalidated because the fact testified is one out of the ordinary course of experience.

Now, when both the good will and the ability, that is, when both the Veracity and Competence of a witness have been sufficiently established, the credibility of his testimony is not to be invalidated because the fact which it goes to prove is one out of the ordinary course of experience. Thus it would be false to assert, with Hume, that miracles, that is, suspensions of the ordinary laws of nature, are incapable of proof, because contradicted by what we have been able to observe. On the

contrary, where the trustworthiness of a witness or witnesses is unimpeachable, the very circumstance that the object is one in itself unusual and marvellous, adds greater weight to the testimony; for this very circumstance would itself induce men of veracity and intelligence to accord a more attentive scrutiny to the fact, and secure from them a more accurate report of their observation.

Summary regarding the Credibility of Testimony in general.

The result of what has now been stated in regard to the credibility of Testimony in general, is:—That a testimony is entitled to credit when the requisite conditions, both on the part of the object and on the part of the subject, have been fulfilled. On the part of the object these are fulfilled when the object is absolutely possible, as an object of the higher faculty of experience,—the Understanding,—the Elaborative Faculty, and relatively possible, as an object of the lower or subsidiary faculties of experience,—Sense, and Self-consciousness. In this case, the testimony, *qua* testimony, does not contradict itself. On the part of the subject the requisite conditions are fulfilled when the trustworthiness, that is, the veracity and competency of the witness, is beyond reasonable doubt. In regard to the veracity of the witness,—this cannot be reasonably doubted, when there is no positive ground on which to discredit the sincerity of the witness, and when the only ground of doubt lies in the mere general possibility of deception. And in reference to the competency of a witness,—this is exposed to no reasonable objection, when the ability of the witness to observe and to communicate the fact in testimony cannot be disallowed. Having, therefore, concluded the consideration of testimony in general, we proceed to treat of it in special, that is, in so far as it is viewed either as Immediate or as Mediate. Of these in their order.

The special consideration of Testimony, when that testimony is Immediate.—An immediate testimony, or testimony at first hand, is one in which the fact reported is an object of the proper or personal experience of the reporter. Now it is manifest, that an immediate witness is in general better entitled to credit than a witness at second hand; and his testimony rises in probability, in proportion as the requisites, already specified, both on the part of its object and on the part of its subject, are fulfilled. An immediate testimony is, therefore, entitled to credit,—1°, In proportion to the greater ability with which the observation has been made; 2°, In proportion to the less impediment in the way of the observation being perfectly accomplished; 3°, In proportion as what was observed could be fully and accurately remembered; and, 4°, In proportion as the facts observed and remembered have been communicated by intelligible and unambiguous signs.

II. Testimony in special, as Immediate and Mediate.

1°, Immediate Testimony.

Conditions of its Credibility.

Now, whether all these conditions of a higher credibility be fulfilled in the case of any immediate testimony,—this cannot be directly and at once ascertained; it can only be inferred, with greater or less certainty, from the qualities of the witness; and, consequently, the validity of a testimony can only be accurately estimated from a critical knowledge of the personal character of the witness, as given in his intellectual and moral qualities, and in the circumstances of his life, which have concurred to modify and determine these. The veracity of a witness either is, or is not, exempt from doubt; and, in the latter case, it may not only lie open to doubt,

Whether all these conditions are fulfilled in the case of any immediate testimony, cannot be directly ascertained.

but even be exposed to suspicion. If the sincerity of the witness be indubitable, a direct testimony is always preferable to an indirect; for a direct testimony being made with the sole intent of establishing the certainty of the fact in question, the competency of the witness is less exposed to objection. If, on the contrary, the sincerity of the witness be not beyond a doubt, and, still more, if it be actually suspected, in that case an indirect testimony is of higher cogency than a direct; for the indirect testimony being given with another view than merely to establish the fact in question, the intention of the witness to falsify the truth of the fact has not so strong a presumption in its favor. If both the sincerity and the competency of the witness are altogether indubitable, it is then of no importance whether the truth of the fact be vouched for by a single witness, or by a plurality of witnesses. On the other hand, if the sincerity and competency of the witness be at all doubtful, the credibility of a testimony will be greater, the greater the number of the witnesses by whom the fact is corroborated. But here it is to be considered, that when there are a plurality of testimonies to the same fact, these testimonies are either consistent or inconsistent. If the testimonies be consistent, and the sincerity and competency of all the witnesses complete, in that case the testimony attains the highest degree of probability of which any testimony is capable. Again, if the witnesses be inconsistent,—on this hypothesis two cases are possible; for either their discrepancy is negative, or it is positive. A negative discrepancy arises, where one witness passes over in silence what another witness positively avers. A positive discrepancy arises, where one witness

When testimony attains the highest degree of probability.

Negative and Positive Discrepancy.

explicitly affirms something, which something another witness explicitly denies. When the difference of testimonies is merely negative, we may suppose various causes of the silence; and, therefore, the positive averment of one witness to a fact is not disproved by the mere circumstance that the same fact is omitted by another. But if it be made out, that the witness who omits mention of the fact could not have been ignorant of that fact had it taken place, and, at the same time, that he could not have passed it over without violating every probability of human action,—in this case, the silence of the one witness manifestly derogates from the credibility of the other witness, and in certain circumstances may annihilate it altogether. Where, again, the difference is positive, the discrepancy is of greater importance, because (though there are certainly exceptions to the rule) an overt contradiction is, in general and in itself, of stronger cogency than a mere non-confirmation by simple silence. Now the positive discrepancy of testimonies either admits of conciliation, or it does not. In the former case, the credibility of the several testimonies stands intact; and the discrepancy among the witnesses is to be accounted for by such circumstances as explain, without invalidating, the testimony considered in itself. In the latter case, one testimony manifestly detracts from the credibility of another; for of incompatible testimonies, while both cannot be true, the one must be false, when reciprocally contradictory, or they may both be false, when reciprocally contrary. In this case, the whole question resolves itself into one of the greater or less trustworthiness of the opposing witnesses. Is the trustworthiness of the counter-witnesses equally great? In that case, neither of the conflictive testimonies is to be admitted. Again, is the trustworthiness of the witnesses not upon a

par? In that case, the testimony of the witness whose trustworthiness is the greater, obtains the preference,—and this more especially if the credibility of the other witnesses is suspected.

So much for the Credibility of Testimony, considered in Special, in so far as that testimony is Immediate or at First Hand; and I now, in the second place, pass on to consider likewise in special, the Credibility of Testimony, in so far as that testimony is Mediate, or at Second Hand.

2°, Mediate Testimony.

A Mediate Testimony is one where the fact is an object not of Personal, but of Foreign Experience. Touching the credibility of a mediate testimony, this supposes that the report of the immediate, and that the report of the mediate, witness are both trustworthy,—this we are either of ourselves able to determine, viz., from our personal acquaintance with its veracity and competence; or we are unable of ourselves to do this, in which case the credibility of the immediate must be taken upon the authority of the mediate witness. Here, however, it is necessary for us to be aware, that the mediate witness is possessed of the ability requisite to estimate the credibility of the immediate witness, and of the honesty to communicate the truth without retrenchment or falsification. But if the trustworthiness both of the mediate and of the immediate witness be sufficiently established, it is of no consequence, in regard to the credibility of a testimony, whether it be at first hand or at second. Nay, the testimony of a mediate may even tend to confirm the testimony of an immediate witness, when his own competence fairly to appreciate the report of the immediate witness is indubitable. If, however, the credibility of the immediate witness be unimpeachable, but

not so the credibility of the mediate, in that case the mediate testimony, in respect of its authority, is inferior to the immediate, and this in the same proportion as the credibility of the second hand witness is inferior to that of the witness at first hand. Further, mediate witnesses are either Proximate or Remote; and, in both cases, either Independent or Dependent. The trustworthiness of proximate witnesses is, in general, greater than the trustworthiness of remote; and the credibility of independent witnesses greater than the credibility of dependent. The remote witness is unworthy of belief, when the intermediate links are wanting between him and the original witness; and the dependent witness deserves no credit, when that on which his evidence depends is recognized as false or unestablished. Mediate testimonies are, likewise, either direct or indirect; and, likewise, when more than one, either reciprocally congruent or conflictive. In both cases the credibility of the witnesses is to be determined in the same manner as if the testimonies were immediate.

Mediate Witnesses are either Proximate or Remote, and either Independent or Dependent.

The testimony of a plurality of mediate witnesses, where there is no recognized immediate witness, is called a *rumor*, if the witnesses be contemporaneous; and a *tradition* if the witnesses be chronologically successive. These are both less entitled to credit, in proportion as in either case a fiction or falsification of the fact is comparatively easy, and, consequently, comparatively probable.

Rumor,—what. Tradition.

LECTURE VIII.—MODIFIED METHODOLOGY.

SECTION I.—OF THE ACQUISITION OF KNOWLEDGE.

I. EXPERIENCE. — B. FOREIGN: — RECORDED TESTIMONY AND WRITINGS IN GENERAL.

II. SPECULATION.

Criticism of Recorded Testimony and of Writings in general.

In our last Lecture, we were engaged in the consideration of Testimony, and the Principles by which its Credibility is governed,—on the supposition always that we possess the veritable report of the witness whose testimony it professes to be, and on the supposition that we are at no loss to understand its meaning and purport. But questions may arise in regard to these points, and, therefore, there is a further critical process requisite, in order to establish the Authenticity,—the Integrity, and the Signification, of the documents in which the testimony is conveyed. This leads to the important subject,—the Criticism of Recorded Testimony, and of Writings in general. I shall comprise the heads of the following observations on this subject in the ensuing paragraph.

Par. XX. Criticism and Interpretation.

¶ XX. The examination and judgment of Writings professing to contain the testimony of certain witnesses, and of Writings in General professing to be the work of certain authors, is of two parts. For the inquiry regards either, 1°, The Authenticity of the document, that is, whether it be, in whole or in part, the product of its ostensible author; for ancient writings in particular are frequently suppositious or interpolated; or, 2°, It regards the Meaning of the words of which it is composed, for these, especially when in languages now dead, are frequently obscure. The former of these problems is resolved by the *Art of Criticism (Critica,)* in the stricter sense of the term; the latter by the *Art of Interpretation (Exegetica* or *Hermeneutica.)* Criticism is of two kinds. If it be occupied with the criteria of the authenticity of a writing in its totality, or in its principal parts, it is called the *Higher*, and sometimes the *Internal, Criticism.* If, again, it consider only the integrity of particular words and phrases, it is called the *Lower*, and sometimes the *External, Criticism.* The former of these may perhaps be best styled the *Criticism of Authenticity;*—the latter, the *Criticism of Integrity.*

The problem which Interpretation has to solve is,—To discover and expound the meaning of a writer, from the words in which his thoughts are expressed. It departs from the principle, that however manifold be the possible meanings of the expressions, the sense of the writer is one. Interpretation, by reference to its sources or subsidia, has been divided into the *Grammatical*, the *Historical*, and the *Philosophical, Exegesis.*

Explication.

Testimonies, especially when the ostensible witnesses themselves can no longer be interrogated, may be subjected to an examination under various forms; and this examination is in fact indispensable, seeing not only that a false testimony may be substituted for a true, and a testimony true upon the whole may yet be falsified in its parts,—a practice which prevailed to a great extent in ancient times; while at the same time the meaning of the testimony, by reason either of the foreign character of the language in which it is expressed, or of the foreign character of thought in which it is conceived, may be obscure and undetermined. The examination of a testimony is twofold, inasmuch as it is either an examination of its Authenticity and Integrity, or an examination of its Meaning. This twofold process of examination is applicable to testimonies of every kind, but it becomes indispensable when the testimony has been recorded in writing, and when this, from its antiquity, has come down to us only in transcripts, indefinitely removed from the original, and when the witnesses are men differing greatly from ourselves in language, manners, customs, and associations of thought. The solution of the problem,—By what laws are the authenticity or spuriousness, the integrity or corruption, of a writing to be determined, —constitutes the Art of Criticism, in its stricter signification *(Critica)*; and the solution of the problem,—By what law is the sense or meaning of a writing to be determined, —constitutes the Art of Interpretation or Exposition *(Hermeneutica, Exegetica)*. In theory, Criticism ought to precede Interpretation, for

The examination of a testimony twofold, —of its Authenticity and Integrity, and of its Meaning.

Criticism.

Interpretation.

the question,—Who has spoken, naturally arises before the question,—How what has been spoken is to be understood. But in practice, criticism and interpretation cannot be separated; for in application they proceed hand in hand.

I. Criticism.

First, then, of Criticism; and the question that presents itself in the threshold is,—What are its Definition and Divisions? Under Criticism is to be understood the complement of logical rules, by which the authenticity or spuriousness, the integrity or interpolation, of a writing is to be judged. The problems which it proposes to answer are,—1°, Does a writing really proceed from the author to whom it is ascribed; and 2°, Is a writing, as we possess it, in all its parts the same as it came from the hands of its author. The system of fundamental rules, which are supposed in judging of the authenticity and integrity of every writing, constitutes what is called the *Doctrine of Universal Criticism;* and the system of particular rules, by which the authenticity and integrity of writings of a certain kind are judged, constitutes the doctrine of what is called *Special Criticism.* It is manifest, from the nature of Logic, that the doctrine of Universal Criticism is alone within its sphere. Now Universal Criticism is conversant either with the authenticity or spuriousness of a writing considered as a whole, or with the integrity or interpolation of certain parts. In the former case it is called *Higher,* in the latter, *Lower, Criticism;* but these denominations are inappropriate. The one criticism has also been styled the *Internal,* the other the *External;* but these appellations are, likewise, excep-

Its problems.

Universal Criticism.

Special Criticism.

Universal Criticism alone within the sphere of Logic.

Its Divisions.

tionable ; and, perhaps, it would be preferable to call the former the *Criticism of the Authenticity*, the latter, the *Criticism of the Integrity*, of a work. I shall consider these in particular ; and, first, of the Criticism of Authenticity.

1. Criticism of Authenticity.

A proof of the authenticity of a writing, more especially of an ancient writing, can be rested only upon two grounds, —an Internal and an External,—and on these either apart or in combination. By *internal grounds*, we mean those indications of authenticity which the writing itself affords. By *external grounds*, we denote the testimony borne by other works, of a corresponding antiquity, to the authenticity of the writing in question.

(a) Internal Grounds. These of themselves not sufficient to establish the authenticity of a writing.

In regard to the Internal Grounds ;—it is evident, without entering upon details, that these cannot of themselves, that is, apart from the external grounds, afford evidence capable of establishing beyond a doubt the authenticity of an ancient writing ; for we can easily conceive that an able and learned forger may accommodate his fabrications both to all the general circumstances of time, place, people, and language, under which it is supposed to have been written, and even to all the particular circumstances of the style, habit of thought, personal relations, etc., of the author by whom it professes to have been written, so that everything may militate for, and nothing militate against, its authenticity.

But omnipotent to disprove this.

But if our criticism from the internal grounds alone be, on the one hand, impotent to establish, it is, on the other, omnipotent to disprove. For it is sufficient to show that a writing is in essential parts, that is, parts which cannot be separated

from the whole, in opposition to the known manners, institutions, usages, etc., of that people with which it would, and must, have been in harmony, were it the product of the writer whose name it bears; that, on the contrary, it bears upon its face indications of another country or of a later age; and, finally, that it is at variance with the personal circumstances, the turn of mind, and the pitch of intellect, of its pretended author. And here it is to be noticed, that these grounds are only relatively internal; for we become aware of them originally only through the testimony of others, that is, through external grounds.

(b) External Grounds.

In regard to the External Grounds;—they, as I said, consist in the testimony, direct or indirect, given to the authenticity of the writing in question by other works of a competent antiquity. This testimony may be contained either in other and admitted writings of the supposed author himself; or in those of contemporary writers; or in those of writers approximating in antiquity. This testimony may also be given either directly by attribution of the disputed writing by title to the author; or indirectly, by quoting as his certain passages which are to be found in it. On this subject it is needless to go into detail, and it is hardly necessary to observe, that the proof of the authenticity is most complete when it proceeds upon the internal and external grounds together. I, therefore, pass on to the Criticism of Integrity.

2. Criticism of Integrity.

When the authenticity of an ancient work has been established on external grounds, and been confirmed on internal, the integrity of this writing is not therewith proved; for it is very possible, and in ancient writings indeed very probable, that particular passages are either interpolated or corrupted.

The authenticity of particular passages is to be judged of precisely by the same laws which regulate our criticism of the authenticity of the whole work. The proof most pertinent to the authenticity of particular passages is drawn—1°, From their acknowledgment by the author himself in other, and these unsuspected, works; 2°, From the attribution of them to the author by other writers of competent information; and, 3°, From the evidence of the most ancient MSS. On the other hand, a passage is to be obelized as spurious,—1°, When found to be repugnant to the general relations of time and place, and to the personal relations of the author; 2°, When wanting in the more ancient codices, and extant only in the more modern. A passage is suspicious, when any motive for its interpolation is manifest, even should we be unable to establish it as spurious. The differences which different copies of a writing exhibit in the particular passages, are called *various readings (variæ lectiones* or *lectiones variantes)*. Now, as of various readings only one can be the true, while they may all very easily be false, the problem which the criticism of Integrity proposes to solve is,—How is the genuine reading to be made out; and herein consists what is technically called the *Recension*, more properly the *Emendation*, of the text.

Emendation of the text,—of two kinds, viz., Historical and Conjectural.

The Emendation of an ancient author may be of two kinds; the one of which may be called *Historical*, the other the *Conjectural*. The former of these founds upon historical data for its proof; the latter, again, proceeds on grounds which lie beyond the sphere of historical fact, and this for the very reason that historical fact is found incompetent to the restoration of the text to its original integrity. The historical emendation necessarily

precedes the conjectural, because the object itself of emendation is wholly of an historical character, and because it is not permitted to attempt any other than an emendation on historical grounds, until, from these very grounds themselves, it be shown that the restitution of the text to its original integrity cannot be historically accomplished. Historical Emendation is again of two kinds, according as its judgment proceeds on external or on internal grounds.

Historical Emendation of two kinds,—External and Internal.

It founds upon external grounds, when the reasons for the truth or falsehood of a reading are derived from testimony; it founds upon internal grounds when the reasons for the truth or falsehood of a reading are derived from the writing itself. Historical emendation has thus a two-fold function to perform (and in its application to practice, these must always be performed in conjunction), viz., it has carefully to seek out and accurately to weigh both the external and internal reasons in support of the reading in dispute. Of external grounds the principal consists in the confirmation afforded by MSS., by printed editions which have immediately emanated from MSS., by ancient translations, and by passages quoted in ancient authors. The internal grounds are all derived either from the form, or from the contents, of the work itself. In reference to the form,—a reading is probable, in proportion as it corresponds to the general character of the language prevalent at the epoch when the work was written, and to the peculiar character of the language by which the author himself was distinguished. In reference to the contents,—a reading is probable, when it harmonizes with the context, that is, when it concurs with the other words of the particular passage in which it stands, in affording a meaning reasonable in itself,

and conformable with the author's opinions, reasonings, and general character of thought.

Conjectural Emendation.

It frequently happens, however, that, notwithstanding the uniformity of MSS., and other external subsidia, a reading cannot be recognized as genuine. In this case, it must be scientifically shown from the rules of criticism itself that this lection is corrupt. If the demonstration thus attempted be satisfactory, and if all external subsidia have been tried in vain, the critic is permitted to consider in what manner the corrupted passage can be restored to its integrity. And here the conjectural or divinatory emendation comes into play; a process in which the power and efficiency of criticism and the genius of the critic are principally manifested.

So much for Criticism, in its applications both to the Authenticity and to the Integrity of Writings. We have now to consider the general rules by which Interpretation, that is, the scientific process of expounding the Meaning of an author, is regulated.

II. Interpretation.

By the *Art of Interpretation*, called likewise technically *Hermeneutic* or *Exegetic*, is meant the complement of logical laws, by which the sense of an ancient writing is to be evolved. Hermeneutic

General or Special.

is either General or Special. General, when it contains those laws which apply to the interpretation of any writing whatever; Special, when it comprises those laws by which writings of a particular kind are to be expounded. The former of these alone is of logical concernment. The problem proposed for the Art of Interpretation to solve, is,—How are we to proceed in order to discover from the words of a writing that sole meaning which the author intended them to convey? In

the interpretation of a work, it is not, therefore, enough to show in what signification its words may be understood; for it is required that we show in what signification they must. To the execution of this task two conditions are absolutely necessary; 1°, That the interpreter should be thoroughly acquainted with the language itself in general, and with the language of the writer in particular; and 2°, That the interpreter should be familiar with the subjects of which the writing treats. But these two requisites, though indispensable, are not of themselves sufficient. It is also of importance that the expositor should have a competent acquaintance with the author's personal circumstances and character of thought, and with the history and spirit of the age and country in which he lived. In regard to the interpretation itself,—it is to be again observed, that as a writer could employ expressions only in a single sense, so the result of the exposition ought to be not merely to show what meaning may possibly attach to the doubtful terms, but what meaning necessarily must. When, therefore, it appears that a passage is of doubtful import, the best preparative for a final determination of its meaning is, in the first place, to ascertain in how many different significations it may be construed, and then, by a process of exclusion, to arrive at the one veritable meaning. When, however, the obscurity cannot be removed, in that case it is the duty of the expositor, before abandoning his task, to evince that an interpretation of the passage is, without change, absolutely or relatively impossible.

Sources of Interpretation.

As to the sources from whence the Interpretation is to be drawn,—these are three in all,—viz., 1°, The *Tractus literarum*, the words themselves, as they appear in MSS.; 2°, The context, that is, the passage in immediate connection

with the doubtful term; 3°, Parallel or analogous passages in the same, or in other writings. How the interpretation drawn from these sources is to be applied, I shall not attempt to detail; but pass on to a more generally useful and interesting subject.

Speculation the Second Means of Knowledge.

So much for Experience or Observation, the first mean of scientific discovery, that, viz., by which we apprehend what is presented as contingent phænomena, and by whose process of Induction and Analogy we carry up individual into general facts. We have now to consider the other mean of scientific discovery, that, viz., by which, from the phænomena presented as contingent, we separate what is really necessary, and thus attain to the knowledge, not of merely generalized facts, but of universal laws. This mean may, for distinction's sake, be called *Speculation*, and its general nature I comprehend in the following paragraph.

Par. XXI. Speculation, — as a means of Knowledge.

¶ XXI. When the mind does not rest contented with observing and classifying the objects of its experience, but, by a reflective analysis, sunders the concrete wholes presented to its cognition, throws out of account all that, as contingent, it can think away from, and concentrates its attention exclusively on those elements which, as necessary conditions of its own acts, it cannot but think;—by this process it obtains the knowledge of a certain order of facts,—facts of Self-consciousness, which, as essential to all Experience, are not the result of any; constituting in truth the Laws by which the possibility of our cognitive functions is determined. This process, by which we thus attain to a discrimi-

native knowledge of the *Necessary*, *Native*, and, as they are also called, the *Noetic*, *Pure*, *a priori*, or *Transcendental*, *Elements of Thought*, may be styled *Speculative Analysis*, *Analytic Speculation*, or *Speculation* simply, and is carefully to be distinguished from Induction, with which it is not unusually confounded.

Explication.

The empirical knowledge of which we have hitherto been speaking, does not, however varied and extensive it may be, suffice to satisfy the thinking mind as such; for our empirical knowledge itself points at certain higher cognitions from which it may obtain completion, and which are of a very different character from that by which the mere empirical cognitions themselves are distinguished. The cognitions are styled, among other names, by those of *noetic*, *pure*, or *rational*, and they are such as cannot, though manifested in experience, be derived from experience; for, as the conditions under which experience is possible, they must be viewed as necessary constituents of the nature of the thinking principle itself. Philosophers have indeed been found to deny the reality of such cognitions native to the mind; and to confine the whole sphere of human knowledge to the limits of experience. But in this case philosophers have overlooked the important circumstance, that the acts, that is, the apprehension and judgment, of experience, are themselves impossible, except under the supposition of certain potential cognitions previously existent in the thinking subject, and which become actual on occasion of an object being presented to the external or internal sense. As an example of a noetic cognition, the following propositions may suffice:—An object and all its attributes are convertible;—All that is has its sufficient cause. The principal distinctions

of Empirical and Rational Knowledges, or rather Empirical and Noetic Cognitions, are the following: —1°, Empirical Cognitions originate exclusively in experience, whereas Noetic Cognitions are virtually at least before or above all experience,—all experience being only possible through them. 2°, Empirical cognitions come piecemeal and successively into existence, and may again gradually fade and disappear; whereas noetic cognitions, like Pallas, armed and immortal from the head of Jupiter, spring at once into existence, complete and indestructible. 3°, Empirical cognitions find only an application to these objects from which they were originally abstracted, and, according as things obtain a different form, they also may become differently fashioned; noetic cognitions, on the contrary, bear the character impressed on them of necessity, universality, sameness. Whether a cognition be empirical or noetic, can only be determined by considering whether it can or cannot be presented in a sensible perception;—whether it do or do not stand forward clear, distinct, and indestructible, bearing the stamp of necessity and absolute universality. The noetic cognitions can be detected only by a critical analysis of the mental phænomena proposed for the purpose of their discovery; and this analysis may, as I have said, be styled Speculation, for want of a more appropriate appellation.

Principal distinctions of Empirical and Noetic Cognitions.

LECTURE IX.—MODIFIED METHODOLOGY.

SECTION I.—OF THE ACQUISITION OF KNOWLEDGE.

III. COMMUNICATION OF KNOWLEDGE.—A. INSTRUCTION—ORAL AND WRITTEN.—B. CONFERENCE —DIALOGUE AND DISPUTATION.

I NOW go on to the last Mean of Acquiring and Perfecting our knowledge; and commence with the following paragraph:

¶ XXII. An important mean for the Acquisition and Perfecting of Knowledge is the Communication of Thought. Considered in general, the Communication of thought is either One-sided, or Mutual. The former is called *Instruction (institutio)*, the latter, *Conference (collocutio)*; but these, though in theory distinct, are in practice easily combined. Instruction is again either *Oral* or *Written*; and Conference, as it is interlocutory and familiar, or controversial and solemn, may be divided into *Dialogue (colloquium, dialogus)*, and *Disputation (disputatio, concertatio)*. The Communication of thought in all its forms is a means of intel-

Par. XXII. The Communication of Thought, — as a means of Acquiring and Perfecting Knowledge.

lectual improvement, not only to him who receives, but to him who bestows, information; in both relations, therefore, it ought to be considered, and not, as is usually done, in the former only.

Explication.

In illustrating this paragraph, I shall commence with the last sentence, and, before treating in detail of Instruction and Conference, as means of extending the limits of our knowledge by new acquisitions derived from the communication of others, I shall endeavour to show, that the Communication of Thought is itself an important mean towards the perfecting of knowledge in the mind of the communicator himself. In this view, the communication of knowledge is like the attribute of mercy, twice blessed,—"blessed to him that gives and to him that takes;" in teaching others we in fact teach ourselves.

The Communication of Thought an important mean towards the perfecting of Knowledge in the mind of the communicator.

This view of the reflex effect of the communication of thought on the mind, whether under the form of Instruction or of Conference, is one of high importance, but it is one which has, in modern times, unfortunately been almost wholly overlooked. To illustrate it in all its bearings would require a volume; at present I can only contribute a few hints towards its exposition.

Man is, by an original tendency of his nature, determined to communicate to others what occupies his thoughts, and by this communication he obtains a clearer understanding of the subject of his cogitations than he could otherwise have compassed. This fact did not escape the acuteness of Plato. In the *Protagoras*,—

Man naturally determined to communication.

This fact noticed by Plato.

"It has been well," says Plato (and he has had sundry passages to the point),—"It has been well, I think, observed by Homer—

> 'Through mutual intercourse and mutual aid,
> Great deeds are done and great discoveries made;
> The wise new wisdom on the wise bestow,
> Whilst the lone thinker's thoughts come slight and slow.'

For in company we, all of us, are more alert, in deed and word and thought. *And if a man excogitate aught by himself, forthwith he goes about to find some one to whom he may reveal it, and from whom he may obtain encouragement, aye and until his discovery be completed.*" The same doctrine is maintained by Aristotle, and illustrated by the same quotation; (to which, indeed, is to be referred the adage,—"*Unus homo, nullus homo.*")—"We rejoice," says Themistius, "in hunting truth in company, as in hunting game." Lucilius,—"*Scire est nescire, nisi id me scire alius scierit;*" paraphrased in the compacter, though far inferior, verse of Persius,—"*Scire tuum nihil est, nisi te scire hoc sciat alter.*" Cicero's Cato testifies to the same truth:—"*Non facile est invenire, qui quod sciat ipse, non tradat alteri.*" And Seneca:—"*Sic cum hac exceptione detur sapientia, ut illam inclusam teneam nec enunciem, rejiciam. Nullius boni, sine socio, jucunda possessio est.*"

Aristotle. Themistius. Lucilius. Persius. Cicero. Seneca.

"*Condita tabescit, vulgata scientia crescit.*"

"*In hoc gaudeo aliquid discere, ut doceam: nec me ulla res delectabit, licet eximia sit et salutaris, quam mihi uni, sciturus sim.*" "*Ita non solum ad discendum propensi sumus, verum etiam ad docendum.*"

The modes in which the Communication of thought is conducive to the perfecting of thought itself, are two; for the mind may be determined to more exalted energy by the sympathy of society, and by the stimulus of opposition; or it may be necessitated to more distinct, accurate, and orderly thinking, as this is the condition of distinct, accurate, and orderly communication. Of these the former requires the presence of others during the act of thought, and is, therefore, only manifested in oral instruction or in conference: whereas the latter is operative both in our oral and in our written communications. Of these in their order.

Modes in which Communication is conducive to the Perfecting of Thought are two.

In the first place, then, the influence of man on man in reciprocally determining a higher energy of the faculties, is a phænomenon sufficiently manifest. By nature a social being, man has powers which are relative to, and, consequently, find their development in, the company of his fellows; and this is more particularly shown in the energies of the cognitive faculties. "As iron sharpeneth iron," says Solomon, "so a man sharpeneth the understanding of his friend." This, as I have said, is effected both by fellow-feeling and by opposition. We see the effects of fellow-feeling in the necessity of an audience to call forth the exertions of the orator. Eloquence requires numbers; and oratory has only flourished where the condition of large audiences has been supplied. But opposition is perhaps still more powerful than mere sympathy in calling out the resources of the intellect.

1. By reciprocally determining a higher energy of the faculties.

(a) Through sympathy.

(b) Through Opposition.

In the mental as well as in the material world, action and reäction are ever equal; and Plutarch well observes, that as motion would cease were contention to be taken out of the physical universe, so progress in improvement would cease were contention taken out of the moral; πόλεμος ἁπάντων πατήρ.

Plutarch.

"It is maintained," says the subtle Scaliger, "by Vives, that we profit more by silent meditation than by dispute. This is not true. For as fire is elicited by the collision of stones, so truth is elicited by the collision of minds. I myself (he adds) frequently meditate by myself long and intently; but in vain; unless I find an antagonist, there is no hope of a successful issue. By a master we are more excited than by a book; but an antagonist, whether by his pertinacity or his wisdom, is to me a double master."

Scaliger, J. C.

But, in the second place, the necessity of communicating a piece of knowledge to others, imposes upon us the necessity of obtaining a fuller consciousness of that knowledge for ourselves. This result is to a certain extent secured by the very process of clothing our cogitations in words. For speech is an analytic process; and to express our thoughts in language, it is requisite to evolve them from the implicit into the explicit, from the confused into the distinct, in order to bestow on each part of the organic totality of a thought its precise and appropriate symbol. But to do this is in fact only to accomplish the first step towards the perfecting of our cognitions or thoughts.

2. By imposing the necessity of obtaining a fuller consciousness of knowledge for ourselves.

But the communication of thought, in its higher applica-

tions, imposes on us far more than this; and in so doing it reäcts with a still more beneficial influence on our habits of thinking. Suppose that we are not merely to express our thoughts as they spontaneously arise; suppose that we are not merely extemporaneously to speak, but deliberately to write, and that what we are to communicate is not a simple and easy, but a complex and difficult, matter. In this case, no man will ever fully understand his subject who has not studied it with the view of communication, while the power of communicating a subject is the only competent criterion of his fully understanding it. "When a man," says Godwin, "writes a book of methodical investigation, he does not write because he understands the subject, but he understands the subject because he has written. He was an uninstructed tyro, exposed to a thousand foolish and miserable mistakes, when he began his work, compared with the degree of proficiency to which he has attained when he has finished it. He who is now an eminent philosopher, or a sublime poet, was formerly neither the one nor the other. Many a man has been overtaken by a premature death, and left nothing behind him but compositions worthy of ridicule and contempt, who, if he had lived, would perhaps have risen to the highest literary eminence. If we could examine the school exercises of men who have afterwards done honour to mankind, we should often find them inferior to those of their ordinary competitors. If we could dive into the portfolios of their early youth, we should meet with abundant matter for laughter at their senseless incongruities, and for contemptuous astonishment.

Influence of Composition and Instruction in perfecting our Knowledge.

Godwin quoted.

"The one exclusive sign," says Aristotle, "that a man is thoroughly cognizant of anything, is that he is able to teach it;" and Ovid,—

Aristotle.

"*Quodque parum novit nemo docere potest.*"

In this reäctive effect of the communication of knowledge in determining the perfection of the knowledge communicated, originated the scholastic maxim *Doce ut discas*,—a maxim which has unfortunately been too much overlooked in the schemes of modern education. In former ages, *teach that you may learn* always constituted one at least of the great means of intellectual cultivation. "To teach," says Plato, "is the way for a man to learn most and best." "*Homines dum docent discunt*," says Seneca. "In teaching," says Clement of Alexandria, "the instructor often learns more than his pupils." "*Disce sed a doctis; indoctos ipse doceto*," is the precept of Dionysius Cato; and the two following were maxims of authority in the discipline of the middle ages. The first—

Plato.
Seneca.
Clement of Alexandria.
Dionysius Cato.

"*Multa rogare, rogata tenere, retenta docere,*
Haec tria, discipulum faciunt superare magistrum."

The second—

"*Discere si quaeris doceas; sic ipse doceris;*
Nam studio tali tibi proficis atque sodali."

This truth is also well enforced by the great Vives. "*Doctrina est traditio corum quae quis novit ei qui non novit. Disciplina est illius traditionis acceptio; nisi quod mens accipientis impletur, dantis vero non exhauritur,—imo communicatione augetur eruditio,*

Vives.

sicut ignis, motu atque agitatione. Excitatur enim ingenium, et discurrit per ea quae ad præsens negotium pertinent: ita invenit atque excudit multa, et quae in mentem non veniebant cessanti, docenti, aut disserenti occurunt, calore acuente vigorem ingenii. Idcirco, nihil est ad magnam eruditionem perinde conducens, ut docere." The celebrated logician, Dr. Robert Sanderson, used to say: "I learn much from my master, more from my equals, and most of all from my disciples."

Sanderson.

But I have occupied perhaps too much time on the influence of the communication of knowledge on those by whom it is made; and shall now pass on to the consideration of its influence on those to whom it is addressed. And in treating of communication in this respect, I shall, in the first place, consider it as One-sided, and, in the second, as Reciprocal or Bilateral.

Influence of the communication of Knowledge on those to whom it is addressed.

The Unilateral Communication of knowledge, or Instruction, is of two kinds, for it is either Oral or Written; but as both these species of instruction propose the same end, they are both, to a certain extent, subject to the same laws.

1. Instruction,—Oral and Written.

Oral and Written Instruction have each their peculiar advantages.

In the first place, instruction by the living voice has this advantage over that of books, that, as more natural, it is more impressive. Hearing rouses the attention and keeps it alive far more effectually than reading. To this we have the testimony of the most competent observers. "Hearing," says Theophrastus, "is of all the senses the most pathetic," that is, it is the

Oral instruction,—its advantages.

(a) More natural, therefore more impressive.

Theophrastus.

sense most intimately associated with sentiment and passion.

Younger Pliny.

"*Multo magis*," says the Younger Pliny, "*multo magis* viva vox *afficit. Nam, licet acriora sunt quæ legas, altius tamen in animo sedent quæ pronuntiatio, vultus, habitus, gestus etiam dicentis adfigit.*"

Valerius Maximus.

"*Plus prodest*," says Valerius Maximus, "docentem audiere, *quam in libris studere; quia vehementior fit impressio in mentibus audientium, ex visu doctoris et auditu, quam ex studio et libro.*"

St. Jerome.

And St. Jerome—"*Habet nescio quid latentis energiæ* viva vox; *et in aures discipuli de doctoris ore transfusa, fortius sonat.*"

(b) Less permanent therefore more attended to.

A second reason why our Attention (and Memory is always in the ratio of Attention) to things spoken is greater than to things read, is that what is written we regard as a permanent possession to which we can always recur at pleasure; whereas we are conscious that the "winged words" are lost to us forever, if we do not catch them as they fly. As Pliny hath it: "*Legendi semper est occasio; audiendi non semper.*"

A third cause of the superior efficacy of oral instruction is that man is a social animal. He is thus naturally disposed to find pleasure in society, and in the performance of the actions performed by those with whom he consorts. But reading is a solitary, hearing is a social act. In reading, we are not determined to attend by any fellow-feeling with others attending; whereas in hearing, our attention is not only engaged by our sympathy with the speaker, but by our sympathy with the other attentive auditors around us.

(c) Hearing a social act.

Such are the causes which concur in rendering Oral

Instruction more effectual than Written. "M. Varillas," says Menage (and Varillas was one of the most learned of modern historians,- and Menage one of the most learned of modern scholars), "M. Varillas himself told me one day, that of every ten things he knew, he had learned nine of them in conversation. I myself might say nearly the same thing."

Menage quoted.

On the other hand, Reading, though only a substitute for Oral Instruction, has likewise advantages peculiar to itself. In the first place, it is more easily accessible. In the second, it is more comprehensive in its sphere of operation. In the third, it is not transitory with the voice, but may again and again be taken up and considered, so that the object of the instruction may thus more fully be examined and brought to proof. It is thus manifest, that oral and written instruction severally supply and severally support each other; and that, where this is competent, they ought always to be employed in conjunction. Oral instruction is, however, in the earlier stages of education, of principal importance; and written ought, therefore, at first only to be brought in as a subsidiary. A neglect of the oral instruction, and an exclusive employment of the written,—the way in which those who are self-taught (the autodidacti) obtain their education,—for the most part betrays its one-sided influence by a contracted cultivation of the intellect, with a deficiency in the power of communicating knowledge to others.

Reading,—its advantages.
(a) More easily accessible.
(b) More comprehensive.
(c) More permanent.

Oral instruction necessarily supposes a speaker and a hearer; and written instruction a writer and a reader. In these, the capacity of the speaker and of the writer must

equally fulfil certain common requisites. In the first place, they should be fully masters of the subject with which their instruction is conversant; and in the second, they should be able and willing to communicate to others the knowledge which they themselves possess. But in reference to these several species of instruction, there are various special rules that ought to be attended to by those who would reap the advantages they severally afford. I shall commence with Written Instruction, and comprise the rules by which it ought to be regulated, in the following paragraph.

Par. XXIII. Written Instruction, and its employment as a means of intellectual improvement.

¶ XXIII. In regard to Written Instruction, and its profitable employment as a means of intellectual improvement, there are certain rules which ought to be observed, and which together constitute the Proper Method of Reading. These may be reduced to three classes, as they regard, 1°, The Quantity, 2°, The Quality, of what is to be read, or, 3°, The Mode of Reading what is to be read.

I. As concerns the Quantity of what is to be read, there is a single rule,—read much, but not many works *(multum non multa)*.

II. As concerns the Quality of what is to be read,—there may be given five rules, 1°, Select the works of principal importance, estimated by relation to the several sciences themselves, or to your particular aim in reading, or to your individual disposition and wants. 2°, Read not the more detailed works upon a science, until you have obtained a rudimentary knowledge of it in general. 3°, Make yourselves familiar with a science in its actual or present

state, before you proceed to study it in its chronological development. 4°, To avoid erroneous and exclusive views, read and compare together the more important works of every sect and party. 5°, To avoid a one-sided development of mind, combine with the study of works which cultivate the Understanding, the study of works which cultivate the Taste.

III. As concerns the Mode or Manner of reading itself, there are four principal rules. 1°, Read that you may accurately remember, but still more, that you may fully understand. 2°, Strive to compass the general tenor of a work, before you attempt to judge of it in detail. 3°, Accommodate the intensity of the reading to the importance of the work. Some books are, therefore, to be only dipped into; others are to be run over rapidly; and others to be studied long and sedulously. 4°, Regulate on the same principle the extracts which you make from the works you read.

I. In reference to the head of Quantity, the single rule is—Read much, but not many works. Though this golden rule has risen in importance, since the world, by the art of printing, has been overwhelmed by the multitude of books, it was still fully recognized by the great thinkers of antiquity. It is even hinted by Solomon, when he complains that "of making many books there is no end." By Quintillian, by the younger Pliny, and by Seneca, the maxim, "*multum legendum esse, non multa*," is laid down as the great rule of study. "All," says Luther in his Table Talk, "who would study with advantage in any art whatsoever, ought to betake

Luther quoted.

themselves to the reading of some sure and certain books oftentimes over; for to read many books produceth confusion, rather than learning, like as those who dwell everywhere, are not anywhere at home." He alludes here to the saying of Seneca, "*Nusquam est qui ubique est.*" And like as in society, we use not daily the community of all our acquaintances, but of some few selected friends, even so likewise ought we to accustom ourselves to the best books, and to make the same familiar unto us, that is, to have them, as we used to say, at our finger ends. The great logician, Bishop Sanderson, to whom I formerly referred, as his friend and biographer Isaac Walton informs us, said "that he declined reading many books; but what he did read were well chosen, and read so often that he became very familiar with them. They were principally three,—Aristotle's *Rhetoric*, Aquinas's *Secunda Secundæ*, and Cicero, particularly his *Offices*." The great Lord Burleigh, we are told by his biographer, carried Cicero *De Officiis*, with Aristotle's *Rhetoric*, always in his bosom; these being complete pieces, "that would make both a scholar and an honest man." "Our age," says Herder, "is the reading age;" and he adds, "it would have been better, in my opinion, for the world and for science, if, instead of the multitude of books which now overlay us, we possessed only a few works good and sterling, and which, as few, would, therefore, be more diligently and profoundly studied." I might quote to you many other testimonies to the same effect; but testimonies are useless in support of so manifest a truth.

Sanderson.

Lord Burleigh.

Herder.

For what purpose,—with what intent, do we read? We read not for the sake of reading, but we read to the end

that we may think. Reading is valuable only as it may supply to us the materials which the mind itself elaborates. As it is not the largest quantity of any kind of food, taken into the stomach, that conduces to health, but such a quantity of such a kind as can be best digested; so it is not the greatest complement of any kind of information that improves the mind, but such a quantity of such a kind as determines the intellect to most vigorous energy. The only profitable reading is that in which we are compelled to think, and think intensely; whereas that reading which serves only to dissipate and divert our thought, is either positively hurtful, or useful only as an occasional relaxation from severe exertion. But the amount of vigorous thinking is usually in the inverse ratio of multifarious reading. Multifarious reading is agreeable; but, as a habit, it is, in its way, as destructive to the mental as dram-drinking is to the bodily health.

End of Reading.

II. In reference to the Quality of what is to be read, the First of the five rules is—"Select the works of principal importance, in accommodation either to the several sciences themselves, or to your particular aim in reading, or to your individual disposition and wants. This rule is too manifestly true to require any illustration of its truth. No one will deny that for the accomplishment of an end you ought to employ the means best calculated for its accomplishment. This is all that the rule inculcates. But while there is no difficulty about the expediency of obeying the rule, there is often considerable difficulty in obeying it. To know what books ought to be read in order to learn a science, is in fact frequently obtained after the science has been already learned. On this point no

II. Quality of what is to be read.

First Rule.

general advice can be given. We have, on all of the sciences, works which profess to supply the advice which the student here requires. But in general, I must say, they are of small assistance in pointing out what books we should select, however useful they may be in showing us what books exist upon a science. In this respect, the British student also labours under peculiar disadvantages. The libraries in this country are, one and all of them, wretchedly imperfect; and there are few departments of science in which they are not destitute even of the works of primary necessity,—works which, from their high price, but more frequently from the difficulty of procuring them, are beyond the reach of ordinary readers.

Second Rule.

Under the head of Quality the Second Rule is—"Read not the more detailed works upon a science, until you have obtained a rudimentary knowledge of it in general." The expediency of this rule is sufficiently apparent. It is altogether impossible to read with advantage an extensive work on any branch of knowledge, if we are not previously aware of its general bearing, and of the relations in which its several parts stand to each other. In this case, the mind is overpowered and oppressed by the mass of details presented to it,—details, the significance and subordination of which it is as yet unable to recognize. A conspectus,—a survey of the science as a whole, ought, therefore, to precede the study of it in its parts; we should be aware of its distribution, before we attend to what is distributed,—we should possess the empty frame-work, before we collect the materials with which it is to be filled. Hence the utility of an encyclopædical knowledge of the sciences in general, preliminary to a study of the several sciences in particular; that is,

a summary knowledge of their objects, their extent, their connection with each other. By this means the student is enabled to steer his way on the wide ocean of science. By this means he always knows whereabouts he is, and becomes aware of the point towards which his author is leading him.

In entering upon the study of such authors as Plato, Aristotle, Descartes, Spinoza, Leibnitz, Locke, Kant, etc., it is, therefore, proper that we first obtain a preparatory acquaintance with the scope, both of their philosophy in general, and of the particular work on which we are about to enter. In the case of writers of such ability this is not difficult to do, as there are abundance of subsidiary works, affording the preliminary knowledge of which we are in quest. But in the case of treatises where similar assistance is not at hand, we may often, in some degree, prepare ourselves for a regular perusal, by examining the table of contents, and taking a cursory inspection of its several departments. In this respect, and also in others, the following advice of Gibbon to young students is highly deserving of attention. "After a rapid glance (I translate from the original French)—after a rapid glance on the subject and distribution of a new book, I suspend the reading of it, which I only resume after having myself examined the subject in all its relations,—after having called up in my solitary walks all that I have read, thought, or learned in regard to the subject of the whole book, or of some chapter in particular. I thus place myself in a condition to estimate what the author may add to my general stock of knowledge; and I am thus sometimes favorably disposed by the accordance, sometimes armed by the opposition, of our views.

Gibbon quoted.

Third Rule.

The third Rule under the head of Quality is—"Make yourselves familiar with a science in its present state, before you proceed to study it in its chronological development." The propriety of this procedure is likewise manifest. Unless we be acquainted with a science in its more advanced state, it is impossible to distinguish between what is more or less important, and, consequently, impossible to determine what is or is not worthy of attention in the doctrines of its earlier cultivators. We shall thus also be overwhelmed by the infinitude of details successively presented to us; all will be confusion and darkness where all ought to be order and light. It is thus improper to study philosophy historically, or in its past progress, before we have studied it statistically, or in its actual results.

Fourth Rule.

The Fourth Rule under the same head is—"To avoid erroneous and exclusive views, read and compare together the more important works of every party." In proportion as different opinions may be entertained in regard to the objects of a science, the more necessary is it that we should weigh with care and impartiality the reasons on which these different opinions rest. Such a science, in particular, is philosophy, and such sciences, in general, are those which proceed out of philosophy. In the philosophical sciences, we ought, therefore, to be especially on our guard against that partiality which considers only the arguments in favor of particular opinions. It is true that in the writings of one party we find adduced the reasons of the opposite party; but frequently so distorted, so mutilated, so enervated, that their refutation occasions little effort. We must, therefore, study the arguments on both sides, if we would avoid those one-sided and contracted

views which are the result of party-spirit. The precept of the Apostle, "Test all things, hold fast by that which is good," is a precept which is applicable equally in philosophy as in theology, but a precept that has not been more frequently neglected in the one study than in the other.

Fifth Rule.

The Fifth Rule under the head of Quality is—"To avoid a one-sided development of mind, combine with the study of works which cultivate the Understanding, the study of works which cultivate the Taste." The propriety of this rule requires no elucidation; I, therefore, pass on to the third head—viz., the manner of reading itself; under which the First Rule is—"Read that you may accurately remember, but still more that you may fully understand."

III. Manner of Reading.

First Rule.

This also requires no comment. Reading should not be a learning by rote, but an act of reflective thinking. Memory is only a subsidiary faculty,—is valuable merely as supplying the materials on which the understanding is to operate. We read, therefore, principally, not to remember facts, but to understand relations. To commit, therefore, to memory what we read, before we elaborate it into an intellectual possession, is not only useless but detrimental; for the habit of laying up in memory what has not been digested by the understanding, is at once the cause and the effect of mental weakness.

Second Rule.

The Second Rule under this head is—"Strive to compass the general tenor of a work, before you attempt to judge of it in detail." Nothing can be more absurd than the attempt to judge a part before comprehending the whole; but unfortunately nothing is

more common, especially among professional critics,—reviewers. This proceeding is, however, as frequently the effect of wilful misrepresentation, as of unintentional error.

Third Rule.

The Third Rule under this head is—"Accommodate the intensity of the reading to the importance of the work. Some books are, therefore, to be only dipped into; others are to be run over rapidly; and others to be studied long and sedulously." All books are not to be read with the same attention; and, accordingly, an ancient distinction was taken of reading into *lectio cursoria* and *lectio stataria*. The former of these we have adopted into English, cursorary reading being a familiar and correct translation of *lectio cursoria*. But *lectio stataria* cannot be so well rendered by the expression of *stationary reading*.

Lectio cursoria.
Lectio stataria.

Bacon quoted.

"Read not," says Bacon, in his Fiftieth Essay—"read not to contradict and confute, nor to believe and take for granted, nor to find talk and discourse, but to weigh and consider. Some books are to be tasted, others are to be swallowed, and some few to be chewed and digested; that is, some books are to be read only in parts; others to be read, but not curiously; and some few to be read wholly and with diligence and attention. Some books also may be read by deputy, and extracts made of them by others; but that would be only in the less important arguments, and the meaner sort of books; else distilled books are, like common distilled waters, fleshy things."

Johann von Müller.

"One kind of book," says the great historian, Johann von Müller, "I read with great rapidity, for in these there is much dross

to throw aside, and little gold to be found; some, however, there are all gold and diamonds, and he who, for example, in Tacitus can read more than twenty pages in four hours, certainly does not understand him."

Rapidity in reading depends, however, greatly on our acquaintance with the subject of discussion. At first, upon a science we can only read with profit few books, and laboriously. By degrees, however, our knowledge of the matters treated expands, the reasonings appear more manifest, —we advance more easily, until at length we are able, without overlooking anything of importance, to read with a velocity which appears almost incredible for those who are only commencing the study.

Fourth Rule.

The Fourth Rule under this head is—"Regulate on the same principle the extracts which you make from the works you read.

So much for the Unilateral Communication of thought, as a mean of knowledge. We now proceed to the Mutual Communication of thought,—Conference.

Conference,—of two kinds.

This is either mere Conversation,—mere Dialogue, or Formal Dispute, and at present we consider both of these exclusively only as a means of knowledge,—only as a means for the communication of truth.

1. Dialogue.

The employment of Dialogue as such a mean, requires great skill and dexterity; for presence of mind, confidence, tact, and pliability are necessary for this, and these are only obtained by exercise, independently of natural talent. This was the method which Socrates almost exclusively employed in the communication of knowledge; and he called it his *art of intellectual midwifery*,

because in its application truth is not given over by the master to the disciple, but the master, by skilful questioning, only helps the disciple to deliver himself of the truth explicity, which his mind had before held implicitly. This method is not, however, applicable to all kinds of knowledge, but only to those which the human intellect is able to evolve out of itself, that is, only to the cognitions of Pure Reason. Disputation is of two principal kinds, inasmuch as it is oral or written; and in both cases, the controversy may be conducted either by the rules of strict logical disputation, or left to the freedom of debate. Without entering on details, it may be sufficient to state, in regard to Logical disputation, that it is here essential that the point in question,—the *status controversiæ*,—the thesis, should, in the first place, be accurately determined, in order to prevent all logomachy, or mere verbal wrangling. This being done, that disputant who denies the thesis, and who is called the *opponent*, may either call upon the disputant who affirms the thesis, and who is called the *defendant*, to allege an argument in its support, or he may at once himself produce his counter-argument. To avoid, however, all misunderstanding, the opponent should also advance an antithesis, that is, a proposition conflictive with the thesis, and when this has been denied by the defendant the process of argumentation commences. This proceeds in regular syllogisms, and is governed by definite rules, which are all so calculated that the discussion is not allowed to wander from the point at issue, and each disputant is compelled, in reference to every syllogism of his adversary, either to admit, or to deny, or to distinguish. These rules you will

2. Disputation,—Oral and Written. Academical disputation.

find in most of the older systems of Logic; in particular I may refer you to them as detailed in Heerebord's *Praxis Logica*, to be found at the end of his edition of the *Synopsis* of Burgersdicius. The practice of disputation was long and justly regarded as the most important of academical exercises; though liable to abuse, the good which it certainly ensures greatly surpasses the evil which it may accidentally occasion.

NOTE BY SIR W. HAMILTON, ... 153

PREFACE.

THE following Essay was written exclusively from the notes which I took while attending SIR WILLIAM HAMILTON'S class in 1845-6, that being the only session during which I ever attended his logical course as a student.

It has thus a certain value, though this be but slight,* as evidence that SIR W. HAMILTON then taught his new doctrine so clearly, that it might be readily apprehended in all its essential points by an ordinary student. In order, therefore, that it may not lose any accidental value which it possesses on this account, the Essay is published as it was originally written. I should not, indeed, have felt myself at liberty, even on other grounds, to have altered it. Accordingly, with the single excep-

* Were it necessary, abundant evidence might be at once obtained to prove that Sir W. Hamilton taught his new doctrine five years earlier than the above date.

tion of a somewhat fuller statement of the three canons of figure, (pages 67, 68,) it is printed without alteration, as at first given in for competition. A few foot-notes have been added while it was going through the press. These are distinguished from the original notes of the Essay by being placed within brackets. Some historical details, too, touching the doctrine which the Essay expounds, have been given in the form of an Appendix. These details, though presenting little attraction to those who have only a general acquaintance with logical science, will, I hope, be found of some interest to its more advanced students.

The few definitions and canons which occur through the Essay, and which are marked with inverted commas, are given from my notes of the lectures. They are, I believe, substantially correct; but as the notes are in many places brief and imperfect, I cannot vouch for their verbal accuracy. The requirements originally prescribed for the Essay are reprinted with it, as they to some extent explain the form which it assumed.

Although at the time when the prize was awarded Sir William Hamilton had suggested to me that

the Essay was of sufficient general interest for publication, still I naturally felt that, in the event of being printed, it would be more satisfactory, both to the public and to myself, to receive some formal confirmation of this. Indeed, as the Essay is mainly devoted to the exposition of SIR W. HAMILTON'S new doctrine, I should not, for a moment, have entertained the idea of publishing it at all without his express sanction. Accordingly, when I first thought of doing so, I applied to SIR W. HAMILTON for this purpose, and received from him the following note, for the kindness of which, I need scarcely say, I feel personally indebted :—

"EDINBURGH, *9th March*, 1850.

"MY DEAR MR. BAYNES,—So far from having any objection to the publication of your Logical Essay, the intention has my fullest approval. When I first perused that Essay, it seemed to me, not only pre-eminently entitled to the annual prize for which it was written, but well deserving of the attention of logical readers in general. This I probably expressed to you at the time. And having now obtained all the highest honours in Philosophy proper which our University offers to her Alumni, I am happy to learn that you propose printing that Essay, in its original form, with the addition of relative

matters furnished by your subsequent thought and reading. I am acquainted with no one who has more zealously—more unexclusively followed out his philosophical and, in particular, his logical researches; your supplement cannot, therefore, fail to be at once curious and important. I would say, that any information from me is at your service, were I not aware that you are laudably desirous to limit your additions to your own resources. I shall only request the annexation of a note, principally for the purpose of showing in what respect my present views may differ from those of mine stated by you in the Essay.* —Believe me," &c.

I have only further to return my best thanks to Sir W. Hamilton for his constant kindness in facilitating my inquiries, giving me free access to his library for works which I could not otherwise have obtained, and in various other ways affording me the benefit of his invaluable counsel and assistance.

THOS. S. BAYNES.

Edinburgh, *May* 23, 1850.

* See Note by Sir William Hamilton, p. 153.

REQUIREMENTS

FOR

ESSAY ON THE NEW ANALYTIC OF LOGICAL FORMS.

Without wishing to prescribe any definite order, it is required that there should be stated in the Essays :—

1° What Logic *postulates* as a condition of its applicability?

2° The reasons why common language makes an *ellipsis* of the *expressed quantity*, frequently of the *subject*, and more frequently of the *predicate*, though both have always their quantities in thought.

3° Conversion of propositions on the *common* doctrine.

4° Defects of this.

5° *Figure* and *Mood* of Categorical Syllogism and *Reduction*,— on *common* doctrine. (General Statement.)

6° Defects of this. (General Statement.)

7° The one *Supreme Canon* of Categorical syllogisms.

8° The evolution from this canon of all the *Species* of Syllogism.

9° The evolution from this canon of all the *General Laws* of Categorical Syllogisms.

10° The error of the *Special Laws* for the several Figures of Categorical Syllogisms.

11° *How Many Figures* are there?

12° What are the *Canons* of the *several Figures?*

13° *How many Moods* are there in *all* the Figures; showing, in concrete examples, through all the Moods, the *unessential* variation which Figure makes in a Syllogism?

14° What relation do the figures hold to *Extension* and *Comprehension?*

15° Why have the *second* and *third* Figures *no determinate major* and *minor premises*, and *two* indifferent *conclusions;* while the *first* Figure has a *determinate major* and *minor premise*, and a *single proximate conclusion?*

16° What relation do the Figures hold to *Deduction* and *Induction?*

April 15, 1846.

NEW ANALYTIC OF LOGICAL FORMS.

THE main principle on which the new Analytic of Logical Forms proceeds is that of a thorough-going quantification of the predicate. This principle in its full scientific significance has been totally overlooked by logicians; and when noticed at all, has for the most part been referred to only to be discarded as useless, if not to be condemned as false.* In conse-

* Dico, signum esse addendum subjecto, nunquam prædicato. Si enim in propositione universali affirmativa signum universale addas prædicato, falsa erit propositio: ut "omnis homo est omne animal." Si vero in universali negativa signum universale, itemque particulari, sive affirmativa fuerit sive negativa, signum particulare addideris prædicatis, propositiones non quidem falsæ fient, sed tamen efficies redundantiam et ταυτολογίαν. *Doctrina Propositionum Disputationibus*, xii. *comprehensa*. à M. Daniele Stahlio. Oxon. 1663. (Disputatio vi. § 16.)

[This is the tradition touching the express quantification of the predicate almost universally prevalent in the Aristotelic schools and commentaries, as will be more fully shown in the Appendix. The *Regulæ Philosophicæ* of Stahl, however, from which it is taken, is an acute and valuable work, faithful to its title, and containing more learning and philosophy than could readily, even in the works of his

quence of this omission, logic as a formal science has received only a one-sided development—has been deprived of much that is scientifically true—encumbered with much that is scientifically false; and

time, be found within the same compass. It long maintained a very high reputation, and was often reprinted, both on the continent and in this country. The first edition was published in 1635, the second in 1641, another in 1653. Several others followed, which were reprinted at London and Oxford; and finally a revised edition appeared in 1676, with notes by the elder Thomasius, who was the master of Leibnitz. From having thus ascertained more accurately the dates of the earlier editions of this work, I can now state with confidence what I had before surmised, viz., that it contains at least a partial anticipation of the distinction which was for the first time fully taken and established in modern philosophy by the Port-Royal logicians,—the distinction, to wit, in notions of the two wholes or quantities, the *comprehensive* and the *extensive*. In answer to the question, how the wider predicate comes to be in its narrower subject; or, what is the same thing, how the whole essence of the genus comes to be in the species; the author says, "Esse prædicatum in aliquo subjecto totum seu universaliter potest dupliciter accipi: primo, *intensive* seu *ratione essentiæ*, et sic animal totum inest homini, et sic quodvis prædicatum superius inest inferiori: secundo, *extensive*, seu *ratione latitudinis* ut hic accipitur, et sic animal non inest totum seu universaliter in homine, quia animal non totum comprehenditur ab ipso, ita ut extra ipsum non sit." (*Reg. Phil.*, p. 687.) The contrasted character of these counter quantities, the intensive, as the *quantity of essence*, the extensive, as the *quantity of extent*, is here given with even scientific precision. Many of the older logicians say in general, (after Aristotle,) that in one sense the species is in the genus, and in another the genus in the species; but I have not found any statement of this distinction before the time of the Port-Royalists at all so precise and explicit as that given in the above passage. Daniel Stahl, beside the *Regulæ*, was the author of a number of other works on Logic, Metaphysics, and Ethics. He was professor of Philosophy in the University of Jena, and died in the year 1654, after having occupied the chair thirty-one years. (*Witteni Memoriæ*, p. 166.)]

throughout its entire history exhibited in a perverted and erroneous form. On the principle of a quantified predicate, however, past evils are corrected, past omissions supplied; and logic receives its highest development in the perfection and simplicity of its form. To exhibit some of the more immediate improvements thus effected by the application of this principle is the design of the following essay. In seeking to accomplish this there will be;—

I. A statement and application of the fundamental postulate of logic, from which application there arises the principle of an expressed quantification of the predicate.

II. The application of this principle (of a quantified predicate) to propositions; and in particular to the doctrine of their conversion, in which the complexity and incompleteness of the old doctrine will be contrasted with the simplicity and perfection of the new.

III. The influence of this principle on the doctrine of categorical syllogisms, in contributing to effect specially; the reduction of their general laws to one; the abolition of their special laws; and from this new simplicity the amplification of the valid forms of reasoning.

[It may, perhaps, be well to state at the outset that in the following essay, when not otherwise stated, we proceed in the whole commonly recognised by logicians—the whole of Extension; understanding,

however, that by changing the copula in propositions, and accompanying this change by a transposition of the propositions in syllogisms, what is said of the one whole of Extension is equally applicable to the counter whole of Comprehension.]

We proceed then—

I. *To state and apply the fundamental postulate of logic. This postulate is,—"That we be allowed to state in language what is contained in thought."*

The application of this postulate to the subject of a proposition is not denied. Logicians *now* universally allow that the subject has a determinate quantity in thought, and this is accordingly expressed in language. With the subject of a proposition we have here, therefore, nothing to do. It is to the predicate that we have to vindicate an interest in the postulate co-equal with that of the subject.

In order to determine this, we must inquire whether a notion holding the place of predicate in a proposition always has a determinate* quantity in thought.

* In order to obviate mistake, we may say that we use the word "*determinate*," in relation to quantity, generically, as including under it *definite* (universal or individual) *and indefinite* (particular). In this sense it is simply opposed to that absence of all expressed quantity which logicians have generally represented by the term *indefinite*. We do not know whether such usage be strictly correct, but adopt it for the sake of convenience.

If it have, then the postulate has an immediate application, and this quantity must be expressed.

In answering this question we shall show—

i. *That the predicate always has a determinate quantity in thought: and* ii., *Explain the reason why this quantity is not generally expressed in common language.*

We proceed to show then—

i. That a notion holding the place of predicate in a proposition always has a determinate quantity in thought.

That this is the case will appear from a little consideration of what a notion is. "A notion or concept"* is defined to be "the cognition or idea of the

* [As this term has fallen out of use, it may be necessary to say a word or two in explanation of its recall. It is employed by Sir W. Hamilton to discriminate in conception the *product* from the *process*. The meaning of the term conception, as commonly used, is ambiguous, since it is employed to denote both the *act* of conceiving and the *product* of that act. The correlative term *concept* removes this ambiguity, since it designates exclusively the product, while the term *conception* is restricted to denote the act of conceiving. It need scarcely be added that these terms are here employed according to their true etymological and scientific meaning, to denote the acts and products of the comparative, and not those of the representative faculty.

We said advisedly that this term had "fallen out of use," inasmuch as it was commonly employed by the older English writers on Logic in its precise scientific significance, to express those generalisations represented by common terms, which are the ultimate elements of logical analysis, and with which the first part of logic has mainly to do. Thus Coke, speaking of first and second notions, says—"Those that primarily imposed names intended to name first the things

general attribute or attributes in which a plurality of objects coincide." This obviously involves the perception of a number of objects—their comparison—the recognition of their points of similarity—and their subjective union by this common attribute. The

themselves, as the word *man* is to express primarily the *conceit* which we form of human nature." Again, "Now the second notions do not directly and by themselves shadow out unto us the things themselves, nor anything accidental or appendant unto them, but point out certain intellectual rules whereby we do with all distinctness and regularity form things, that is the *conceits* of things." (*Art of Logick*, p. 11.) And again, speaking of the various relations of words, he says quite explicitly—"The formal is the signification of the word, and by consequence the relation to the *conceit* of the mind which it giveth knowledge of." (P. 15.) Fraunce also uses the term continually. Thus, to take a single example in defining an axiom, he says, "It here signifieth any sentence or proposition whatsoever wherein one argument, reason, *conceipt*, thing, is so conjoined with, or severed from another, as that thereby we judge the one eyther to bee or not to bee, the cause, effect; whole, part; generall, speciall; subject, adjunct: divers, disparate; relative, repugnant; like, unlike; equall more or less to the other." (*Lawyer's Logick*, fol. 87.) See another instance of this use from Fraunce in the quotation given at p. 23 (note). The term is also used by Granger in his "Divine Logick;" and, if I remember aright, by Wilson in his "Rule of Reason." It is to be found, too, employed in the same sense out of logical works, and is used in this way by writers of authority; we may specify as examples among others Dr. Henry More, and Sir W. Raleigh. All that now remains to us of this old use is the restricted sense in which the word *conceit* is employed—a sense at once so restricted and so established as to unfit it for scientific use. *Concept*, as strictly analogical in form and precise in meaning, is exactly the term we need to express the simplest products of the comparative faculty; and, as we have shown, it already exists in the language. What is necessary, therefore, in employing it, is not an apology for its introduction, but simply a vindication of its recall.]

possibility of this process determines the possibility of knowledge to man. Had he no power of classifying in intellect the confused multitude of objects presented in sense, he must remain for ever destitute of anything worthy of the name of knowledge. With no clear recognition even of the individual, since comparison and discrimination would be impossible, he must for ever abide amidst the obscurity and vagueness in which knowledge commences—helpless amidst a multiplicity of objects which he could not comprehend—bewildered by a confusion which there was no possibility of recalling to order. The earliest effort of the mind is accordingly directed to extricate itself from this confusion ; and this determines the exercise of the comparative faculty, and the formation of concepts or notions.

Amidst the multitude of confused objects presented to the mind in perception, some are found to affect us similarly in certain respects. These objects the mind considers ; by comparison it recognises their resembling qualities ; by attention these are exclusively considered, since the concentration of the mind on those qualities in which objects coincide involves of necessity its abstraction from those in which they are severally dissimilar. These various objects, since the resembling attributes which they possess in common cannot, when considered alone, be discriminated, are, in this restricted point of view, considered as one. In other words, the mind grasps into

unity a multitude of objects severally distinct by a common point of identity. On this unity thus formed it sets the seal of a name, that it may be enabled ever afterwards at once to discriminate the various objects of its knowledge, commodiously refer each to its own class, and thus be saved the endless labour of enumerating all the particulars by which objects are individually discriminated. A notion is thus a purely ideal or subjective whole, which the mind from the limitation of its powers is necessitated to form, in order to classify in thought and discriminate in language the various objects of its knowledge.

This being the case, it is obvious that a concept or notion can afford only a partial knowledge, and has only a relative existence. It can afford only a partial knowledge, since it embraces some only of the many marks by which an object is known. It has only a relative existence, since this knowledge is not given absolutely, but only in connexion with some one of the objects to which the concept is related. For a notion, though potentially applicable to all the objects which it contains, can only be truly known on occasion of its being actually applied to some one of these objects. This is at once the test and the evidence of its relative character. And this being its character, it is obviously altogether dependent on the objects from which it is formed. A notion has thus, in its totality, a purely subjective existence, destitute of any objective reality. Being what it is

—an ideal whole only by relation to the objects whose resembling part it embraces—it is obvious, as we have said, that it can pretend to no independent existence, much less to any independent knowledge. Its existence entirely depends on that of the objects from whence it is derived, and to each of which it is linked by the common resembling attribute which it embraces. Destroy the objects, you destroy the resembling attributes in each; and destroying the resembling parts, you annihilate the whole which they together constituted. As, however, a concept has only a subjective being, existence and knowledge are here identical. If no qualities be discriminated in objects as similar, we have no knowledge of a concept—no concept exists. If we cannot assign an object to any class—cannot say it does or does not belong to any notion, we do not comprehend it. We think an object (recognise to be what it is) only as we think it under some notion or concept.

This being premised with regard to notions in general, it will be seen, that when we bring an object under a notion, *i.e.*, when we predicate of it that it belongs to such a class, we must know that it occupies a certain place in that class. For if we were uncertain what place the individual object occupied in the class, or whether it occupied any place at all, we should not know the class, and could not, therefore, bring any object under it;—*e.g.*, If I do not know whether *rose* comes under the concept *flower*

—whether it is equal to some part, or the whole, or superior to it—I do not know the class *flower*, and cannot, of course, predicate flower of rose; in other words, I cannot bring *rose* under the concept *flower*, since I do not know what the concept means, what it contains, and what it does not. This is clear; for as we have just explained—since a notion, as a factitious unity in thought, is absolutely worthless, and, indeed, not cognisable, out of relation to the individual objects, the aggregate of whose resembling qualities it constitutes; and since an object is truly known only as it is thought through or under a notion, it follows, that comprehension, in such a case, would be impossible. If, therefore, we understand the object at all, we must fix, in thought, the sphere which it occupies under the class to which, in predication, we have assigned it. In other words—if we comprehend what we utter, *every notion holding the place of predicate in a proposition must have a determinate quantity in thought.*

This, indeed, is always involved in predication. For predication is nothing more or less than the expression of the relation of quantity in which a notion stands to an individual, or two notions to each other. If this relation were indeterminate—if we were uncertain whether it was of part, or whole, or none—there could be no predication. The very fact of predication is thus always evidence that the predicate notion holds a relation of determinate

quantity to the subject. In other words, we think only as we think under some determinate quantity; for all thought is comparison of less and more, of part and whole. All predication is but the utterance of thought. All predication must, therefore, have a determinate quantity.

Since, therefore, the quantity always exists in thought, the postulate applies; that is, in logic the quantity must be expressed, on demand, in language.

It only remains to remark here, that this quantity of the predicate notion, always determinate, will be *definite*, (universal or individual,) or *indefinite*, (particular,) as the subject notion is greater, equal to, or less than the predicate. If the subject notion be less, we attribute to it a part only of the predicate—say it is some part, but not the whole, which that notion comprises, *e.g.*, "*all man is some mortal.*" If the subject be equal to the predicate, we attribute the whole notion to it, *e.g.*, "*all man is all rational.*" If the subject be greater, we attribute the whole predicate to it, as a part only of its extension, *e.g.*, "*some mortal is all man.*"

Logicians who have occasionally touched upon the quantification of the predicate, seem for the most part to have conceived the possibility of its express quantification only universally;* and because this

* Notandum, signum universalitatis non esse apponendum prædicato, sed tantum subjecto; rectè enim dicitur, "*omnis homo est animal;*" sed non rectè dicitur, "*omnis homo est omne animal.*"

cannot be done in a great number of cases—in all those cases, indeed, in which an individual is brought under a concept, or a species under a genus, (as we cannot say, "all man is all mortal,")—since this cannot be done, to have lightly thereupon thrown aside the whole doctrine as of no avail. It is, however, clear, from the nature of a notion as a whole made up of the like characters in a number of objects which thus stand to it in the relation of parts, that we are quite as much at liberty to say of one of these objects, that it forms a part of the notion, as we are to say of all the objects together, that they constitute the whole.* We may, therefore, and in

Verum duæ limitationes adhiberi possunt: Prima, ut intelligatur de universalibus affirmatis non autem de negatis; recte enim dicitur "*omnis homo est nullus asinus*," "*nullus asinus est omnis homo*:" Secunda, ut signum universalitatis immediatè ponatur ante prædicatum; nam si apponatur tantùm adjuncto prædicati, enunciatio non erit falsa, ut "*visus percipit omnem colorem*," "*Christus curabat omnem morbum*," &c. Quia adjunctum ejusmodi poterit fieri subjectum, mutando verbum activum in passivum hoc pacto, "*omnis color percipitur a visu.*" *Davidis Derodonis Logica Restituta.* Geneva, 1659. (Page 573.)

On the catholic doctrine held by logicians touching the quantification of the predicate, see the Appendix.

* [The older logicians laid down many rules which were often useless, sometimes false, and at best of only partial and limited application, about what they termed the regular and irregular order of predication—the natural or unnatural, direct or indirect, consecution of the terms in a proposition. Natural, or regular, or direct predication (*predicatio naturalis, directa, ordinata*) they held to be that in which the genus is predicated of the species, the species of the individual, the attribute of its subject, and in general the exten-

fact we must continually quantify the predicate particularly.

sive whole of its part; and in which, therefore, the subject notion was always of less extent than the predicate notion. Unnatural, indirect or irregular predication (*predicatio non naturalis, indirecta, inordinata*) was the reverse of this, that, to wit, in which the species was predicated of the genus, the subject of its attribute, and in general the extensive part of its whole.

Language is, however, but the instrument of thought; and its natural order in the last resort must ever be that in which it best expresses the thought of which it is the vehicle. What this order shall be will thus in great measure be determined by the feeling and purpose of the speaker. If he have a special interest in any particular term, or wishes in any way to make it emphatic, it will occupy the more prominent and important place in the proposition. The order in such a case will be that of interest and emphasis, and this surely is as natural an arrangement as any other. Accordingly, if I wish to direct particular attention to the genus, it may stand first in the proposition, and the species follow as its predicate. Thus, for example, if referring to the Scaligers I were to say, "An acute philosopher was the father, an erudite philologer the son," there would be nothing unnatural in this, for by such an arrangement of the terms, I simply direct special attention to the different departments of science in which they respectively excelled. So, again, in the line of the poet, "The proper study of mankind is man;" and in a number of other examples that will readily suggest themselves. With equal justice, if I wish to make the species (or genus) emphatic, I may predicate the individual of it, *e.g.*, in the expressions, "A philosopher, indeed, was Socrates;" "The poet of all time is Shakspeare;" there is nothing unnatural, but attention is appropriately directed to the high type of poetic and philosophic character which respectively belonged to these great men.

It is no valid objection to this form of predication to say, that in all such cases we do in reality so restrict the genus or species, that they become convertible with the species or individual severally predicated of them; for this objection lies equally against all predication whatever. Thus, in what is termed the regular form, the genus is never

We proceed then—

ii. To explain why the quantity of the predicate is not expressed in common language.

We have already explained the nature of a con-

taken in the whole of its extent, but only in so much of it as is occupied by the species of which it is predicated, *e.g.*, when we say, "All man is animal," we do not of course mean *all* animal, but simply that *part* of animal which is convertible with man, or as is sometimes more explicitly stated, "Man is an (one) animal," or, (if referring to the race,) "a species of animal."

So, again, in relation to the second division of what is called unnatural predication—that in which the subject is predicated of its attribute—if we wish specially to signalise the attribute that will naturally stand first, *e.g.*, in the exclamation, "Great is Diana of the Ephesians," the greatness of Diana is far more emphatically marked than it would be if the terms were reversed. So, again, in the line, "The fairest of her daughters, Eve," it is to the beauty of Eve that special attention is directed.

It may be at once conceded to the logicians, that what they have termed the natural or direct order, is the more common, inasmuch as the concrete terms of a proposition are generally of greater interest than the abstract ones; but it is unjust to speak of any other order of predication as unnatural or unlawful, while it is quite obvious that, logically considered, either order of consecution in the terms of a proposition is equally valid, for we may indifferently predicate a part of the genus of the whole species, or the whole species of a part of the genus. This liberty, indeed, is not denied, though it is generally, nevertheless, even by late writers, allowed as an exception rather than as a rule. Thus Gassendi, after giving the rule that the species cannot be predicated of the genus, says, in mitigation of its force—"Additur nihilominus, *nisi generi limitatio adhibeatur;* dicere enim possumus, ut jam ante insinuatum est, *aliquod animal est homo; certus quidam color est candor; una quæpiam virtus est justitia.* Efficitur nempe, ut particulis hujusmodi limitantibus genus veluti contrahatur, neque amplius pateat, quam species; ac proinde ut species de eo enunciari, fierive illius attributum reciproce possit." (*Logica.* Oxon. 1718, p. 367.)]

cept—that it is a factitious whole obtained from a number of individual objects, each of which, therefore, occupies a certain part of the whole concept. We have also shown, that this relation of quantity is always present to the mind, when a concept and an individual (or a part and whole of any kind) are thought together as subject and predicate. Though always thus contained in thought, this quantity is, however, rarely expressed in ordinary language. The name in which the totality of attribute embraced by the concept is fixed, is usually applied to any one of its individual objects, without any particle of quantification. The explanation of this omission is to be found in the end which common language seeks. The end which it proposes to itself is the clear utterance of meaning; it seeks to render at once intelligible, by its signs, *the thing signified.* As a vehicle for the conveyance of thought, ordinary language is mainly concerned about *what is thought*—not the *manner of thinking it.* In other and more technical terms, it is primarily engaged with the *matter of thought*, and only considers the *form* incidentally, and as a mean to an end. Whatever, therefore, is not really necessary to the clear comprehension of what is contained in thought, is usually elided in expression. Thus common language abounds with abbreviations and elliptical forms of expression. The expression of those phases of thought and feeling which arise in conjunctions of

circumstances which are frequent and familiar, are almost always and conveniently of this description, *e.g.*,—we meet a friend and say, "*good morning.*" What is intended here? A cordial greeting and the expression of friendly feeling. This, however, is not expressed in terms, but the elliptical form above is understood to represent, "I wish you a good morning." So also in "farewell," and a multitude of other cases which might be adduced. In fact, so that what is meant by it be at once clearly intelligible, an expression, however elliptical, is true and valid for all the purposes of ordinary language. Thus, to facilitate the communication of thought, not only are words omitted, but the steps of the reasoning process itself are for the most part abbreviated. Common language almost invariably makes an ellipsis of one step of this process. For since the reasoning process is the same in all men—being governed by laws necessary and universal—the mind at once and intuitively supplies the omitted step, and the process is complete. This principle, too, affords the true explanation why, in common language, the overt quantification of the predicate is neglected. It is not necessary for the clear comprehension of a proposition that the predicate be quantified in terms. And the reason why this is not necessary is to be found in the universality of generalisation or the formation of concepts, and the sameness of the process in all men. All men must generalise, for the

necessity which determines this process exists in all. All men must generalise alike, for the faculties which accomplish it are the same in all. In order to comprehend the many objects by which he is surrounded, he must reduce them to order. To accomplish this, he classifies or groups into unity a number of objects which affect him in the same manner. But as the same objects affect all men in the same manner, it follows, that where the same term exists to express the same mental modification, this term may and will be applied to all the individual objects which determine such similar impressions.

As all men, therefore, know what is meant by a general term,—that it is a name equally applicable to all and each of the individual objects which it embraces, when one of these objects is brought under it; that is to say, when it is predicated of this object that it forms a part of the notion which the general term expresses, it is not absolutely necessary overtly to declare that it forms only some part; for as it is universally known that the concept is of far wider extension, the quantity is immediately supplied in thought, and no mistake arises. Thus, when we say, "*Every horse is an animal*"—"*All men are mortal*," it is not necessary to say that there are other animals besides horses, or to guard explicitly against the conclusion that man alone is mortal; for as the extension of the general terms is understood by all, every one knows at once, by a reference to the matter

of the thought, that in each case the predicate is affirmed of its subject only in *some part* of its extension, not in the whole.

Since, therefore, it is not necessary, for the clear understanding of a proposition, that the predicate notion be expressly quantified, and as the continual repetition of it would be wearisome, the quantification is usually omitted; in other words, *since it is not necessary for the purposes which ordinary language seeks to accomplish, the quantity of the predicate, though always contained in thought, is usually elided in expression.*

All this, however, becomes widely different when in the progress of reflective inquiry a science arises, which seeks, as its express aim, to accomplish a full and final analysis *of the form of thought.* It will be the office of such a science to supply for its own purposes the omissions of common language—to restore whatever of the form of thought may have fallen out of expression in ordinary parlance. The procedure of logic and that of common language are thus different, and to some extent opposed; the former recalling to expression as of scientific value what the latter had thrown aside as of no account. The different nature of their procedure is, as we have hinted, determined by the different nature of the ends which they respectively seek to accomplish. Common language, as we have seen, seeks as its end to exhibit with *clearness the matter of thought.* What-

ever does not contribute to this is thrown aside as worthless. Logic, on the other hand, seeks as its end *to exhibit with exactness the form of thought.* Whatever contributes to this is retained as of scientific value. All the elements which the analysis of the form of thought furnishes must be brought out to view, and explicitly considered. Whatever does not belong to the form of thought must be cast aside as without the province of the science. We have seen, that in thought the predicate notion of a proposition is always of a given quantity. This quantity is not expressed in common language ; because, by a knowledge of, and reference to, the matter of thought, the omission is at once supplied. This procedure is, however, of course incompetent to logic. As a formal science, it knows nothing of the matter of thought ; it makes no elisions ; it can understand nothing ; it can supply nothing ; it can only recognise and deal scientifically with what is given formally. If, therefore, the predicate has always a certain quantity in thought, (and we have shown it has,) that quantity must be expressed before it can be logically taken into account, and its significance investigated. The recognition of the expressed quantity of the predicate is then as imperative in logic as the neglect of such recognition is convenient in common language ; for it is plain that, unless all the elements furnished by analysis be received and considered in their relative influence and importance, the

science cannot pretend to completeness. Logic, in common with all sciences, seeks perfection; but, as a formal science, it can only realise scientific perfection as it attains to formal exactness. The condition of its formal exactness is, that its analysis of the form of thought be exhaustive and complete. As soon as this is the case, synthesis may commence, and the science will emerge in its full beauty and true perfection.

This explains how it is that logic has remained so imperfect and deformed in the hands of all previous logicians. They were, in the main, right as far as they went; but they did not go far enough. Their investigation of the form of thought was arrested before it had attained the necessary completeness. Proceeding in their analysis, they correctly recalled to expression what common language had omitted in the reasoning process, and exhibited the three steps of that process in their formal order and completeness. Still continuing their analysis, they proceeded to investigate the properties of a proposition in order to determine its scientific capabilities. Here they discovered that the subject has always a certain quantity in thought. This quantity, in conformity with the necessities of their science, they accordingly expressed, and turned to scientific account. But here their analysis was stopped, just at the very point the investigation of which would have conferred upon their science the completeness which it lacked;

and, as the natural result of a defective analysis, logic, as a science, has always remained incomplete. Had logicians proceeded further, they would have discovered that a determinate quantity always belongs, not only to the subject of a proposition, but also to the predicate; that the recognition of this quantity in logic affords an important principle, the true application of which would relieve it of its many inconsistencies, and confer upon it scientific perfection. It will be our business presently to inquire into some of the improvements thus effected.

To recapitulate, then:—We have seen, from the nature of a notion in general, and of a predicate notion in particular, that it always has a determinate quantity in thought. We have thus vindicated to it an interest in the fundamental postulate of logic. And from the application of that postulate there has emerged the principle—*That the quantity of the predicate notion of a proposition be explicitly noted in logic.*

We proceed now to show—

II.—*The application of this principle to propositions, and in particular to the doctrine of their conversion.*

A proposition is defined to be "the expression in language of the relation of congruence or confliction, in which two notions, two individuals, or an individual

and a notion, (in a word, two terms,) are recognised, when compared together, to stand to each other." *

This being the nature of a proposition, it is evident that it involves a plurality of ideas,† thought together in mutual relation and dependence; since it is only by being viewed in relation as subject and predicate, determining and determined, that a plurality of thoughts can be reduced to a mental oneness, and recognised together in the same individual act of consciousness.

The terms of a proposition are thus always related, and this relation constitutes their scientific significance. To investigate this relation fully, and determine it exactly, is the office of logical analysis. As a proposition is the expression of the relation of congruence or confliction between two thoughts, it is surely of the highest importance—in fact, a condition of its intelligible existence—that the amount of this agreement or difference be known and stated. This can only be done by ascertaining the quantity of both the terms, and thus determining the space of each in relation to the other. Until this be done, the properties of a proposition have not been fully analysed; its scientific capabilities cannot be fully determined. The quantity of the terms in relation

* "*Judicium* est comparatio ideæ cum idea; *propositio* est judicium terminis expressum."—*Ploucquet.*

† Using the term "idea" generically, to include the products of sense, imagination, and intellect.

to each other is thus the most important aspect in which a proposition can be considered ; but though thus the most important relation, it is one in the analysis of which logicians in general seem to have been more than commonly unsuccessful. In opposition to the obvious importance and necessity of determining the quantity of the terms in a proposition, they have introduced into logic a class of propositions distinguished by the absence of all quantity;* and this, too,

* [The class of propositions distinguished by the absence of all expressed quantity, and termed by logicians *indefinite*, (more properly *indesignate*,) affords another curious illustration of how completely the force of authority has in logic prevailed over the most obvious and elementary necessities of the science. Introduced originally by Aristotle, and subsequently reproduced by Boëthius, these propositions have continued to occupy a place in the science, and to be discriminated as a separate class, under the division of quantity. In the absence of all expressed quantity, however, it was very difficult to turn them to any logical account. Some kind of quantity was necessary for this purpose ; but the only way in which they could be quantified with any certainty was *particularly*, according to the caution of Apuleius, who says, referring to the division of propositions under the head of quantity, " Aliæ indefinitæ, ut *animal spirat*, non enim definit utrum omne, an aliquod. Sed tamen pro particulari semper valet. Quia tutius est id ex incerto accipere quod minus est." (*De Syllogismo Categorico. Apuleii Opera.* Lugd., 1600, p. 415.)

Subsequently, however, as stated in the text, rules for determining this quantity were laid down, derived from the object-matter of the propositions themselves. By Ramus, indeed, and some of his followers, indefinites, it would seem, were altogether rejected as of no logical account. His English representative, Fraunce, (I have not Ramus' own works at hand,) says, referring to the indefinite proposition, " But Ramus expelleth that uncertaine and indefinite axiom; for every conceipt of the mind is determinatly eyther generall or

in opposition to the fundamental postulates of their science :—that in order to deal with a proposition we must know what it means—*i.e.*, understand the quantity of its subject and predicate—and that we be

speciall, and speciall eyther particular or singular." (*Lawyer's Logike*, fol. 92.)

They continued, nevertheless, to be currently received, and a later English writer but reflects this common acceptance when he makes them the matter of special legislation. " The canons hereof," says Coke, speaking of this class, " are two." He then gives the following, which are, however, but translations and abridgments from Keckermann :—

" 1. The chief force and use of indefinites is in propositions of the idea : that is in such as where the universal subject is taken absolutely, as—the Lord's Supper is a sacrament ; man is the noblest creature ; the soul of man is immortal, &c.

" 2. There is also a use of indefinites to signifie that the consequent is in the antecedent, for the most part, though not always, ὡς ἐπὶ τὸ πολύ. As, the *Cretians* be lyars ; mothers are too much cockerers of their children," &c. (*Art of Logick*, p. 106.)

A recent British writer, however, sees far more clearly into their true logical character and relation, and says of them, (referring to the rules which are given for their reduction,) with far more scientific than historic truth, " By reduction here is to be understood that logicians recognise no indefinite propositions, and that if an indefinite occur, they require it to be expressed in a definite form. Indefinite propositions are noticed that the logician should be on his guard against them, and not because they are legitimate, or of any legitimate class." (*Thynne's Compendium of Logic.* Dublin, 1827, p. 47.)

This is far from being historically true, and if it were, it would not avail to defend the position which indefinites occupy ; for the principle of their reduction is as extra-logical as are the propositions to be reduced. In the statement, that they are not recognised in logic as a separate class, this author has at once overrated the acuteness of his predecessors, and underrated his own ; for it is only within a comparatively short period that their logical position has been seri-

allowed to express all that is understood. As an antidote to the disorders thus introduced into their science, they have had recourse to an extra-logical remedy ; that is to say, they have laid down a number of rules for determining the quantity of these unquantified propositions, founded on the object-matter of these propositions themselves, according as this matter is possible or impossible, necessary or contingent. In so doing they have, implicitly at least, destroyed their science ; for if logic be competent to this discrimination, it can no longer vindicate to itself the character of a special science, but must become co-extensive with the whole domain of human knowledge. They have thus also destroyed the possibility of its thorough-going application, since they have tacitly laid down, as a preliminary to such application, the impossible condition that we should

ously called in question. They are, however, as need scarcely now be stated, to be rejected from logic as utterly unscientific in their character. They belong, indeed, to the same confusion of the accidental with the essential, through which the enthymeme was discriminated as a separate form of reasoning. In both the mere *contingencies of speech* are identified with the *necessities of thought;* and the *accidents of expression* are received and incorporated with the science as valid *elements of form.* Science, however, is no longer worthy of the name when it accepts and incorporates, without examination, the rude materials which it is its office to elaborate ; and places among its elements the confused wholes, which a more searching analysis would have decomposed into their constituent parts. This is precisely what has happened in relation to the indefinite proposition and the enthymeme ; and accordingly, by a truer scientific analysis, they are finally rejected from logic.]

know all that is possible and all that is impossible, all that is contingent and all that is necessary. To say nothing of its logical inconsistency,—this being impossible is, as a scientific demand, absurd.

Logicians have not, however, of course left propositions generally in this unquantified state, or their science would have remained hopelessly crippled. They proceeded, as we have already said, to consider the quantity of propositions; but here their inconsistency still attends them, and they are destined to be again unsuccessful. For in their analysis, as we have seen, they have only considered the subject, and determined its quantity, while that of the predicate, which it was equally necessary to determine, as being of equal scientific value, is altogether neglected. The proximate influence of this omission in introducing complexity and inconsistency into the science will be seen in the common doctrine of conversion; while some of its remoter consequences will be hereafter signalised. It may be well to premise here that we speak of categorical propositions throughout. We go on, then, to notice *the conversion of propositions on the common doctrine.* When the subject and predicate of a proposition change places, the proposition is said *to be converted.*

This conversion is threefold.

1. *Simple conversion.*—This takes place when the terms are simply transposed, without any change of quantity or quality in the proposition. This is com-

petent in universal negative and particular affirmative propositions; *e.g.*,—

No man is a stone. Therefore,
No stone is a man.
Some man is a tinker. Therefore,
Some tinker is a man.

2. *Conversion per accidens.*—This takes place when the quality of the two propositions remains the same; but the quantity is altered, the predicate in the one being limited on becoming the subject of the other. This holds true in universal propositions, both affirmative and negative;* *e.g.*,—

All violets are flowers. Therefore,
Some flowers are violets.

* [This is the statement of Peter Hispanus, and it has been repeated by Derodon and some others among the later logicians. The application of this species of conversion to universal negatives is, however, altogether useless, as they are converted simply, and thus retain their universality after conversion. It is, moreover, incompetent, inasmuch as, in such a process, an inference of subordination is involved.

By the majority of logical writers it is therefore applied exclusively and formally to universal affirmative propositions. As so applied, however, the name which it bears is unsuitable, since it no longer truly designates the nature of the process which it is employed to express. Taken in this exclusive application, *restrictive* or *attenuate* conversion (the name given to it by Granger) would be much better.

It is worth while noticing, that the logicians in general do not seem to be at all aware by whom this term, *per accidens*, as applied to conversion, was introduced, or what was the kind of process which it was originally employed to denote. None refer to its authorship, while few attempt any explanation of its meaning; and the few who do are for the most part incorrect. Isenach, whose "*Epitome Dia-*

3. *Conversion by contraposition.**—This takes place when the quality of the propositions remains unaffected; but the terms are changed into what is called by logicians infinite, but more appropriately

lecticæ" was published about the year 1510, says, in explanation, that this species of conversion was called *per accidens*, because one of the accidents of the proposition (quantity, to wit) was changed. Keckermann gives a somewhat different and longer account of it. He says, that this kind of conversion is called *per accidens*, because the converted is not *immediately* inferred from the converse, but only *mediately* through the intervention of another proposition; *e.g.*, from the proposition "all man is animal," it is not *immediately* inferred that "some animal is man," but rather that "some man is animal;" and as this can be converted simply, it follows that "some animal is man." (*Systema Logicæ.* Francof, 1628, p. 348.) While a recent Oxford writer gives the following not very intelligible explanation:—"Per accidens—putting in the place of the subject the quality, whether proprium or accident, which the predicate implies. By the old logicians the proprium is constantly called accidens proprium." (*Moberly's Lectures on Logic.* Oxford, 1848, p. 85.) It is difficult to see how this statement (even supposing it to be just as far as it goes) can be accepted as a full account of the matter,—inasmuch as it can at best only apply to those cases in which the predicate is the property or accident of the subject, and by no means to the generic latitude of possible predication to which the conversion extends. Ploucquet is the only one among modern logicians, so far as my knowledge extends, who seems to have understood the sense in which it was originally employed, and who has accordingly given the true explanation of the term. He says, explaining the significance of the letter P (per accidens) in the mnemonic verses, "Notat universalem in particularem, et particularem in universalem esse convertendam, id quod fit *per accidens*, ex natura *materiæ*." (*Fundamenta Phil. Spec.* Tubingæ, 1758, p. 45.) This is the true explanation of the term, and of the process which it originally designated, as employed

* Some logical writers, it appears, have rejected this species as of no logical value.—*Crackanthorpe*, Book iii. chap. 10.

indefinite, by the addition of negative particles ; that is to say, when in the converted proposition, instead of the subject and predicate simply, the contradictory of each is found ; *e.g.*,—

Every man is mortal. Therefore,
Everything which is not mortal is not man.

by Boëthius,* who was the author of this species of conversion, name, and thing. This term was employed by him to denote the conversion of the universal into the particular, and the particular into the universal, from the *accident of the matter* of the proposition. He says, " Harum (propositionum) igitur, particularis affirmatio, particulariter quidem sibi ipsa convertitur, universali autem affirmationi *per accidens*, et rursus universalis negatio, loco principe sui recepit conversionem, ad particularem vero negationem *per accidens* converti potest. Nec vero negationis particularis ad seipsam principaliter stabilis ac firma conversio est, sed negationi universali secundo loco atque accidentaliter." *Introductio ad Syllogismos.* (*Opera, Basil.* 1546, p. 575.)

But the *formal* conversion, (to be carefully distinguished from the *material* conversion of Boëthius,) which the term was subsequently and exclusively employed to denote, had been discriminated long before the time of Boëthius. It was expressly taken by Aristotle, and called by him *partial* or *particular* conversion, (*ἀντιστροφὴ ἐν μέρει.*) *Anal. Pr.* i. c. 2, § 1.). It was subsequently also signalized by Apuleius under the name of *reflex* conversion. His words are, " Universalis autem dedicativa et ipsa quidem non est conversibilis, sed particulariter tamen potest converti : ut cum sit *omnis homo animal*, non potest ita converti, ut sit *omne animal homo ;* sed particulariter potest, *quoddam animal homo.* Verum hoc in simplici conversione, quæ in conclusionum illationibus *reflexio* nominatur." (*Opera Omnia*, Lugd., 1600, p. 419.)

It may seem useless to have dwelt so long on this kind of conversion in the very act of abolishing it ; but that it is dead is no reason whatever why so venerable a member of the ancient system should not receive decent burial.]

* For the reference to Boëthius I am indebted to Sir W. Hamilton.

This holds true in universal affirmative and particular negative propositions. The rules* governing conversion are given by different logicians with numerical differences; in substance, however, they are much the same. But as the enumeration would be tedious, and the nature of the process in its different species is evident from the statement of each, we shall not repeat them here.

We might remark on this process generally, that it is, for the most part, logically incompetent; since in the second species we interpolate a quantity not formally given, and in the third create an entirely new proposition by new terms.

But we pass on to remark, specially, *that the whole doctrine of conversion, as commonly understood, is on the principle of the new analytic false and useless.*

This inconsistent and cumbrous doctrine resulted, as we have said, from a false analysis by logicians of the elements with which they had to deal. The whole doctrine is founded upon the relation of quantity between the subject and predicate in a proposition; but if a principal element of that relation be left out, the doctrine will of course be defective. Logicians stand chargeable with this neglect. They commenced to recompose their system before, by thorough decomposition, they had obtained all the elements requisite

* *Crackanthorpe* gives five, *Wallis* six, another British writer twelve.—*The Port-Royal* three, reduced to two.

for that purpose; and to remedy the deficiencies thus occasioned, they have had recourse to the complicated process briefly stated above;—thus, with labour and difficulty—and even then imperfectly—by a complex process, and a number of particular rules, effecting that which a simple proximate principle of their science would, if recognised, have spontaneously and perfectly accomplished. As this confusion and complexity has arisen from a faulty analysis, so a perfect analysis at once introduces order and simplicity. A full decomposition of the elements contained in thought discovers that the predicate is always of a given quantity in relation to the subject; that this is known and recognised as the condition of predication. It thus reveals that the relation between the terms of a proposition is one not only of similarity, but of *identity;* that the subject and predicate of a proposition, when the relation of each to the other is recognised, and both are quantified, are always necessarily simply convertible; that the terms of a proposition, in short, are of an absolute equality, and all predication an equation of subject and predicate. Quantify the predicate, and two notions of different extension are at once brought into equality; the sphere of an individual object in a notion is marked out, and that sphere becomes absolutely convertible with the object; *e.g.*,—

All man is some animal.
Some animal is all man.

Some men are all philosophers.
All philosophers are some men.

Boëthius is some Roman.
Some Roman is Boëthius.

Thus, on the principle of the new analytic the whole doctrine of ordinary conversion, with its complex species and its manifold rules, passes away, and the whole process becomes as practically simple as it is scientifically complete. The terms of a proposition are exhibited in their true relation, and that relation reduces all the species of conversion to one—*that of simple conversion.* Thus, in the words of an acute writer, whose apt statement in relation to this doctrine is true in a far wider application than he designed it—to the whole and not to a part alone of the doctrine of conversion. "Omnes conversionum leges pendent à cohæsione, vel potius ab identitate subjecti et attributi: quod si enim subjectum conjungitur et *identificatur* ut aiunt, cum attributo, necesse est pariter attributum *uniri* et *identificari* cum subjecto." *

We proceed to consider—

III. *The influence of this principle on the doctrine of categorical syllogisms, in contributing to effect,* 1°, *the reduction of their general laws to one;* 2°, *the*

* "*Philosophia Burgundica,*" 1678, tom. i. Institutiones Logicæ. Sect. Secunda, cap. 2. (By Du Hamel.)

abolition of their special laws: and from this new simplicity the amplification of the valid forms of reasoning.

We premise a word or two on the nature of a syllogism in general, and of a categorical syllogism in particular.

" A syllogism is the product of that act of mediate comparison, by which we recognise that two notions stand to each other in the relation of whole and part, through the recognition that these notions severally stand in the same relation to a third."

A syllogism or reasoning is thus like a concept and a judgment the product of the comparative faculty—the comparison of part and whole. This indeed is the characteristic of all reasoning—alike of the simple syllogism and of the most lengthy and profound argument. All reasoning is but the comparison and determination of wholes and parts. As in concepts various attributes, in judgments various thoughts, are compared in order to determine the relation of part and whole subsisting between them; so in reasoning two notions are compared together with a third in order to determine their connexion with each other—the only difference being the higher complexity which in this case the act of comparison assumes. A reasoning thus *differs* from a judgment in the superior complexity of the act, in being an immediate act of comparison in which two notions, whose relation

to each other is unknown, are compared together through a third, whose connexion with both is recognised. But it *agrees* with a judgment in being an undivided act of mind ; for as the connexion of part and whole between two notions, enounced by a reasoning, is determined by the recognition of their mutual relation to a third ; and as relatives are only recognised together, it follows that it is an undivided act of consciousness.* A syllogism indeed forms as truly a mental whole as a concept, though each is capable of being subsequently analysed for scientific purposes into its constituent elements. On being subjected to such analysis, every true syllogism or reasoning is found to contain three, and no more than three, propositions, each of which has three, and only three, terms. There will be three propositions, since the two notions, touching whose relation the mind is in doubt, are both compared with another whose relation to each is manifest. This affords two propositions, in one of which the third notion is a contained part in relation to one of the doubtful notions ; and in the other a containing whole in relation to the other doubtful notion. And there is of necessity the conclusion in which the doubt is dispelled, and the relation of the two notions themselves determined. This process is in every valid syllogism determined by a law of thought, and the connexion is thus one

* Hic modus (per syllogismum) ratiocinandi est ex simplissimis, et intuitivè uno actu mentis perspicitur.—*Ploucquet.*

of absolute necessity. There will, it is obvious, be as many valid kinds of syllogism as there are different laws of thought on which they may be respectively founded.

A categorical syllogism is one in whose major premise the relation of the terms is simple; whose procedure is determined and whose conclusion is necessitated by the laws of identity and contradiction.

Having premised thus much about syllogisms in general, and categorical syllogisms in particular, we shall proceed—

i. *To state with brevity the common doctrine of syllogistic figure, mood, and reduction; and then generally some of the defects by which it is characterised.*

And,

ii. *To state the one supreme canon of the new analytic, which potentially contains the whole doctrine of categorical syllogisms, and then proceed to develop from it some parts of that doctrine.*

We proceed then—

i. *To state the common doctrine of syllogistic figure, mood, and reduction.*

Figure.—What is commonly termed by logicians syllogistic figure arises from the relation of the middle term as subject or predicate to the extremes. The four possible varieties of position which the middle

term may occupy in the premises thus determine four syllogistic figures.

In the *first figure* the middle term is the subject of the major premise, and the predicate of the minor; *e.g.*,—

All rational is risible.
All man is rational.
Therefore—All man is risible.

The laws of this figure are—

1. That the subsumption* be affirmative.

* [These words sumption and subsumption are new, and may therefore require a few words of explanation if not of defence. They are introduced and employed by Sir William Hamilton to express the two first propositions of a syllogism, instead of the common designations major and minor premise.

We much need apt terms by which to express these members of the syllogism, and for the creation of new or introduction of foreign words in such a relation, may certainly urge the first part of the plea of Lucretius, "propter egestatem linguæ," if we cannot go on to add with him, "et rerum novitatem." The members to be named are old enough, but they still have never received precise and discriminative epithets, at least in our logical terminology. The terms major and minor premise are objectionable, if for no other reason, from the confusion of terms with propositions likely enough to arise from the omission of the second member of the term, and the consequent indiscriminate use in hasty reference of the epithets major and minor alone. Single, precise, and discriminative words would on every account be far better than these combinations. The term *propositio* was the designation of the major premise of a syllogism, from the days of Cicero downwards, with few exceptions. Among these exceptions are Quintilian who uses *intentio*, Boëthius who sometimes uses *sumptum*, and Rodolphus Agricola who employs *expositio*. *Assumptio* was even more generally the designation of the second proposition of the syllogism—the minor premise. So that, in fact, when the two first members of a syllogism are not (after Aristotle) called the major

2. That the sumption be universal.

In the *second figure*, the middle term is the predicate in each premise; *e.g.*,—

No liar is to be believed.
Every good man is to be believed.
Therefore—No good man is a liar.

and minor proposition, the terms *proposition* and *assumption* are generally found employed to express them. These terms all more or less shadow forth the relation of subordination which exists between these parts of the syllogism. This relation is, however, far more aptly and explicitly denoted by the correlative terms *sumption* and *subsumption;* and as we have already assume and assumption with other cognate terms, there is no reason why we should not also avail ourselves of the convenient terms subsumption and subsume.

Even the terms sumption and subsumption are not, however, equal to the whole extent of the necessity, for between the two first members of syllogisms, in the second and third figures, there is no such relation of subordination as they express, so that it is only by courtesy to custom that these terms can be applied to them. The same is true of the reasoning from wholes to wholes; so that we still need terms of generic latitude sufficient to express the two first members of *any* syllogism. For all ordinary purposes, however, the above are sufficient. They have the great merit of being single and precise epithets; and after what has been said, their use in the figures cannot be misunderstood.

The only thorough-going and consistent attempt ever made, that I am aware of, to render the technicalities of logical science into English terms, was that of Ralph Lever, Dean of Durham. In his logical treatise, entitled, "The Art of Reason, rightly termed *Witcraft*, teaching a perfect way to argue and dispute," and published in London in the year 1573, he expressly undertakes to accomplish this. He explains and defends his procedure in the preface, (*forespeach,*) of which the following extract may be taken as a specimen:—"For trial hereof I wish you to aske any English man, who understandeth neither Greek nor Latin, what he conceiveth in his mind when he heareth this word, a *backset*, and what he doth conceive when he heareth this term, a *predicate*. And doubtlesse he must confesse, if

The laws of this figure are—

1. That one of the two premises be negative ; and consequently that the conclusion be so.

2. That the sumption be universal.

In the *third figure*, the middle term is the subject in both premises ; *e.g.*,—

All man is risible.
All man is capable of science.
Therefore—Some capable of science is risible.

The laws of this figure are—

1. That the subsumption be affirmative.

2. That the conclusion be particular.

In the *fourth figure*, the middle term is the predicate in the sumption and the subject in the subsumption ; *e.g.*,—

All oranges are fruit.
All fruit is refreshing
Therefore—Some refreshing things are oranges.

he consider the matter aright, or have any sharpnesse of wit at al, that by a *backset* he conceiveth a thing that must be set after, and by a *predicate* that he doth understand nothing at all." He accordingly renders every (or certainly almost every) technical term of common use in logic by combinations of purely Saxon words. We will give both as a specimen of his coinage, and as pertinent to the purpose of the present note, the terms which he has used to express the different members of the syllogism. These are *foresay* and *endsay, first foresay*, (major premise,) *second foresay*, (minor premise,) *endsay*, (conclusion ;) or, in his own words,—" The two first shewsayes (propositions) that are placed in a reason by rule, are called foresayes—the third may be termed an endsay." (*Art of Witcraft*, p. 103.) These terms are sufficiently general for *any* form of syllogism ; but as the technical terms of the science are all of Latin derivation, Saxon compounds cannot be accepted.]

The laws of this figure are—

1. When the sumption is affirmative, the subsumption is always universal.

2. When the subsumption is affirmative, the conclusion is particular.

3. If either of the premises be negative, the sumption must be universal.*

Mood.—What is called mood is a modification of a syllogism, determined by the quantity and quality of the propositions of which it is composed. All the figures admit of syllogistic variations thus determined. Four kinds of propositions are, according to logicians, afforded by the various possible combinations of quantity and quality. Universal affirmative, (A)—universal negative, (E)—particular affirmative, (I)—particular negative, (O.) And as there are three propositions in every syllogism, all the possible combinations of quality and quantity will be sixty-four. Of these sixteen are excluded from having negative premises; twelve from having particular premises; twelve more for having a negative premise with an affirmative conclusion; eight, from one of the premises being particular, but the conclusion universal; and, finally, four more from having a negative conclusion where both premises were affirmative. There are thus left twelve moods. Of these, however, for various particular reasons, six

* These laws are taken from the *Port-Royal Logic*, but they are substantially the same in most logical systems.

only are allowable in each figure, making twenty-four in all. Of these, however, five are again thrown out of account from having a particular conclusion where a universal is competent. There thus remain in all the figures only nineteen valid moods. These are embodied in the well-known lines—"*Barbara Celarent,*" &c.

Reduction.—Logicians, though altogether ignorant of the true character of figure, strictly so called, seem always, however, to have felt, that the form of reasoning in the first figure was more exact than in the three others, and the conclusion afforded by it more logically direct and satisfactory. They have, accordingly, devised a process for changing syllogisms of the three other figures into those of the first. *This process is technically termed reduction.* Reduction is twofold—

1. *Reductio ostensiva.*—This is effected by the conversion and transposition of propositions; *e.g.*—*Disamis* of the third figure into *Darii* of the first.

Disamis.

Some tyrant is unjust.
All tyrants are cruel.
Some cruel is unjust.

Here the major premise and conclusion are first converted, and then the premises transposed; thus—

Darii.

All tyrants are cruel.
Some unjust are tyrants.
Some unjust are cruel.

2. *Reductio ad impossibile.*—This is effected, not directly, but indirectly, by proving that the contradictory of the syllogism under examination is something impossible or absurd. This is accomplished by taking the contradictory of the conclusion with one of the premises, and inferring from these the contradictory of the other premise—in the second figure the contradictory of the minor—in the third the contradictory of the major premise. Thus—*Baroco* of the second into *Barbara* of the first figure:

Baroco.

All rational is risible.
Some animals are not risible.
Some animals are not rational.

Barbara.

All rational is risible.
All animal is rational.
All animal is risible.

Such, on the common doctrine, is a short account of syllogistic figure, mood, and reduction. We go on *to state generally some of the defects by which this doctrine is characterised.*

1. *The whole doctrine is cumbrous and unsatisfactory.*

In addition to the general laws which are laid down by logicians as governing all syllogisms, and the various kinds of syllogism which have been signalised, we have here what are represented as four new essential variations of the syllogistic form, each

guarded by its own complement of special laws—forming altogether a code of particular rules for the detection of petty offences, which is certainly sufficiently intricate and perplexing. Now, the necessity of these empirical laws is not attempted to be vindicated on any thorough-going logical principle; and until it be, we think their minute and multiform character is valid ground of objection. No right, moreover, has been established, that we know of, for the three last figures themselves, to occupy the place they do as true variations of the syllogistic form, except a prescriptive right, which in logic, where so many false principles have for so long usurped authority, and so many true ones been ignored, when unaccompanied by any other, is rather ground for suspicion than otherwise. Accordingly, till a better right than this be shown why they should be considered independent syllogistic forms, their want of conformity to recognised law in their procedure, and the indirectness of their conclusions, furnish good ground of dissatisfaction with their logical position.

Next we have *the moods* in each figure—the testing of the true moods in each by its particular laws—these laws determining the exclusion in one figure of moods that are held valid in another; and this exclusion thus necessarily producing a numerical difference of moods in different figures. That what is a true mood in one figure should be a false one in another, is, to say the least, unsatisfactory.

And, finally, we have the doctrine of REDUCTION—the most cumbrous and unsatisfactory part of the whole. The first half of the process involves a procedure opposed to other parts of the common doctrine, since it admits the transposition of premises at will. (Of this, however, more presently.) The procedure of the second half of the process is almost ingeniously perplexed and cumbrous, and when accomplished, so far as we see, answers no end whatever. We form an entirely new syllogism, which throws no light upon the old; illustrates no part that was before obscure; gives us, indeed, no knowledge at all. The old figure remains with its irregularity (if it had any) uncorrected; with its illegal aspect (if that were its vice) unremoved. It is, in short, cumbrous without the justification of being useful; and most unsatisfactory it should seem in the mere wantonness of being so, since it cannot urge the extenuating plea of necessity.

2. *This doctrine is inconsistent.*

We begin by noticing the inconsistency displayed in the discrimination of moods on the common doctrine. We have seen that the principle on which the discrimination of moods proceeds, is the difference in quantity and quality of the propositions which constitute a syllogism. In order to determine a variation of mood in a syllogism, one at least of its propositions must differ, in one or other of these respects, from all other co-ordinate moods. If in

two syllogisms of a given figure there be no difference, either of quantity or quality in the propositions of which they are composed, these syllogisms are logically reckoned as one and the same: there is in this case no modal variation. This at least is the common doctrine, if that doctrine have any meaning. In opposition thereto, however, we have discriminated as true varieties *in the second figure*—

Camestres.

All wise men are truly happy.
No intemperate man is truly happy.
No intemperate man is a wise man.

Cesare.

No intemperate man is truly happy.
All wise men are truly happy.
No wise man is an intemperate man.

And in the third figure—

Datisi.

Every true patriot is brave.
Some true patriots are persecuted.
Some that are persecuted are brave.

Disamis.

Some true patriots are persecuted.
Every true patriot is brave.
Some who are brave are persecuted.

Now, the syllogisms thus given under each figure have no difference whatever in the quantity or qua-

lity of their propositions ; they are, therefore, according to the theory of logicians, *the same.* Practically, however, they have been considered from time immemorial as distinct ; as constituting valid variations of syllogistic form under each figure. If this be so, the principle on which the discrimination of mood avowedly proceeds is, at least, implicitly given up, and another is introduced—*that of the transposition of propositions ;* for it is on this principle alone that the syllogisms given above can be vindicated as distinct. If, however, the transposed order of propositions be recognised as affording a worthy principle for the discrimination of syllogistic difference, then a number of new forms will emerge, of which logicians have taken no account. The catalogue of syllogistic variations will immediately be swelled far beyond its present limits, since every existing variety is capable, by the transposition of its propositions, of receiving a fivefold amplification. It is clear, however, that the transposed order of propositions affords no principle of any scientific value in the discrimination of syllogisms ; and, what is more to the present purpose, it is equally clear, that whatever be its value, it is one which has not been recognised by logicians, since they have not even incidentally adverted to it in the exposition of their doctrine. The principle of modal variation on that doctrine is manifestly the difference of propositions in quantity and quality. In obvious inconsistency, however, with this

recognised law, there remain the syllogisms stated above.

But a more important, if not more glaring inconsistency remains to be noticed *in the correlative doctrines of figures and reduction.** The opposition here is so great that it seems to us truly marvellous that they should ever have existed together. They appear mutually and triumphantly to destroy each other. We will endeavour to explain what we mean in a few words. *The inconsistency may be stated thus:* In the cogency of formal proof there can be no degrees. Logic, it need hardly be repeated, is a formal science, proceeding from, and determined through its whole course by, *the laws of thought.* This being the case, every true variation of the syllogistic form will afford a conclusion equally valid and direct; since a form of reasoning is true only as determined by a law of thought, and the laws of thought are equally universal and imperative. If a given syllogistic form be determined as original and essential, it is already self-sufficient; it needs no help, it can receive none. No process can be devised for bestowing on its conclusion a higher validity than that which it possesses of its own inherent right. For, as we have said of formal proof, there can be no degrees of cogency. In every case it is alike valid and direct. With

* Throughout the ensuing discussion we use "*figure*" simply in the sense of *figure strictly so called, i.e.*, to the exclusion of the first, in order to avoid constant circumlocution.

respect, therefore, to every true variation of syllogistic form, *what is called reduction is useless.*

On the other hand, if the conclusion afforded by a syllogism be one-sided and indirect, and its form, therefore, apparently imperfect or irregular, there is good ground for suspicion that there is some complexity or confusion in its form, which it is necessary to disentangle or clear away before the syllogism emerges in its purity, and before, therefore, its true form can be correctly determined. When this confusion or complexity is removed—and it is the office of logical analysis to accomplish this—the syllogism will appear in its real character, and naturally fall under some determinate class of recognised syllogistic form. To such a syllogism what is called *reduction* is obviously inapplicable, since we cannot talk of reducing a syllogism of a given form to itself. Thus, on either alternative, the doctrine of *reduction* seems alike inapplicable, if not impossible. *If the syllogistic form be essential, reduction is useless; if it be accidental, it is absurd.*

Logicians, however, so far as we can understand the common doctrine, seem to have chosen the former, and perhaps milder alternative,—that the figures are true variations of syllogistic form. If this were not the case, it would have been explicitly stated; and, in fact, the doctrine of reduction itself is at once the evidence that they so regarded them, and the proof that this is not their true character. If they did not so consider them,

it is difficult to account for the existence of reduction at all; for it is introduced expressly to strengthen the position of the figures, and to vindicate to their conclusions the highest validity. Not clearly comprehending the true nature of the figures, their doctrine respecting them was imperfect. They determined that they were true syllogistic varieties, but still felt that this was not perfectly satisfactory—that there was something wanting in their doctrine; and in order to bestow upon it the requisite completeness, they unhappily fell upon the doctrine of reduction—a process which, so far from establishing the truth of that which it was introduced to demonstrate, is the clearest evidence of its falsehood. In fact, we cannot but regard the whole doctrine as the work of a most perverse and suicidal ingenuity. Introduced as a bulwark of strength to the figures, it becomes the very mockery of their weakness, and affords its sustaining aid only in the moment of their dissolution. For we certainly cannot understand how a doubtful variation of syllogistic form is vindicated as valid and essential through a process which accomplishes its destruction; in other words, by being changed into a form, of the validity of which there is no question.

But even granting that the whole doctrine was, in the main, correct, it is chargeable with inconsistencies of detail; such as the explicit recognition at one time of a determinate major and minor premiss in the figures, and the implicit denial of this at an-

other. These, however, it is not necessary now to notice. Suffice it to have shown that the related doctrines of figure and reduction are most seriously inconsistent, if not mutually destructive of each other.

3. *The common doctrine is destructive of the science itself.*

We bring this charge against the common doctrine —and it is the gravest of all—that it is destructive of the science, by implicitly, at least, impeaching the veracity of the laws of thought upon which the science is founded.

This may be illustrated in one or two ways. In all categorical syllogisms the reasoning is founded upon the law of identity, that a whole is identical with all its parts, a concept with its attributes, &c., and thus that " a part of a part is a part of the whole." The reasoning, therefore, if it be valid, always of necessity involves the subordination of one part to a whole through a larger part.*

* [This statement requires some modification ; for, on the law of identity, the reasoning from wholes to wholes is as competent as that from parts to wholes. By this law we are entitled to infer the relation of identity between two wholes, from the perception that they stand in this relation to a common third whole, just as certainly as we are to infer the relation of inclusion between a given whole and part, from the perception that these stand in the same relation to a common third part ; *e.g.*, the reasoning all B is all A, all C is all B, therefore all C is all A, is just as competent as the reasoning all B is A, all C is B, therefore all C is A. Taken absolutely, therefore, the objection stated in the text will not stand the test of criticism. Considered relatively to the common doctrine, it is, however, valid. On that doctrine all direct formal reasoning from wholes to wholes

Now, the common doctrine recognises the figures strictly so called as ultimate varieties of syllogistic form; implicitly, at least, declares that they are simple forms, and their reasoning valid as it stands. But in these figures there is no subordination of lesser parts to wholes through larger parts.

It is therefore clear that if the law, according to which all true reasoning is affirmed to proceed, enjoins this subordination, but that there are found, and recognised as valid, forms in which there is no such subordination—that the law is no longer trustworthy; for having proved mendacious once, its character of necessity and universality has departed, and it may deceive again. Thus, implicitly at least, the main foundation of all reasoning is cut away.

Again, we have seen in the common doctrine the numerical inequality of the moods under different figures. In each figure some mood is determined as valid which is ignored by the rest. Thus throughout the whole scheme moods are retained as true at one time which are rejected as false at another.

Now, what is the test by which the validity and

is impossible. For a direct reasoning from wholes to wholes is only possible through the express quantification of the predicate, which the forms and rules of the common doctrine alike forbid. In every reasoning which obeys these rules, the extent of some one term in the syllogism is necessarily left indeterminate, so that its identity of extent with any other term cannot be formally inferred. On the common doctrine, the reasoning is thus necessarily from parts to wholes. Taken with this explanation, therefore, the statement in the text may stand.]

invalidity of any and every variety of syllogism is determined? No other *than its obedience to, or violation of, the laws of thought.* If a syllogism agrees with these laws, it is true; if not, it is false. This criterion imperatively determines every possible variation of syllogistic form. If a syllogism be true to the laws of thought in its formal essence, no accidental irregularity or transposition in the arrangement of its parts can render it invalid; if it be not thus true in the inward essence of form, no outward regularity of expression can supply the wanting validity. In other words, what the laws of thought allow, no schematic difference can ever ignore; what the laws of thought condemn, no schematic variation can ever successfully vindicate.

In direct opposition to all this stands the common doctrine. Judged by the above standard, its whole procedure is most illegal. In its admissions and exclusions of syllogistic variety it is equally capricious and empirical; and throughout it is consistently regardless of the great laws by which the whole process, as a logical procedure, must be ever determined. We find a certain mood rejected under a given figure—we presume because it is invalid; but it can be invalid only because it violates the laws of thought. Presently after we find this same mood reappearing in another figure, and recognised as scientifically true. What the laws of thought erewhile condemned, the schematic difference now tri-

umphantly interposes to allow. What we had supposed to be rejected from the science as logically false, now boldly returns under express scientific sanction.

Thus, on the common doctrine, *the accidents of arrangement* triumph over the *essentials of form:* the *contingencies of expression* are of higher authority than the *necessities of thought.* In a formal science we have its accidental arrangement actually dethroning its essential principles; contingent and particular irregularities boldly usurping that authority, through the legitimate exercise of which they would have been themselves exiled,—that authority through the recognition of which alone the science can be preserved—the authority of *law necessary and universal.*

If the procedure which issues in these results be competent, then it is evident that logic exists no longer; for the destruction of the science is obviously involved in the destruction of the laws on which it is exclusively founded. And this destruction of the laws of thought is, as we have shown, in effect accomplished by the common doctrine, in the practical contradictions of these which its procedure involves. It thus implicitly contains in it principles which, if fully developed, would overthrow logical science.

We have thus seen amongst the more general defects which belong to the common doctrine, that it is practically cumbrous and unsatisfactory; that it

is theoretically inconsistent; and that it involves principles destructive to the science itself. The special falsity and uselessness of this doctrine will appear more fully in detail under the division to which we now proceed.

ii. *To state the one supreme canon of the new analytic, which potentially contains the whole doctrine of categorical syllogisms, and then to develop from it some parts of that doctrine.*

That canon is—" What worse relation of subject and predicate subsists between either of two terms and a common third term, with which both are related, and one at least positively so—that relation subsists between these two terms themselves."

This canon, as we have said, involves the whole doctrine of categorical syllogisms; determines every kind of such syllogisms; and is to them an all-sufficient and exhaustive code of law, observing which none can be formally invalid.

We have now to show, in conformity with the purpose of this essay in general, and its third division in particular, the influence which the principle of a quantified predicate has in accomplishing the reduction of syllogistic rules to this single canon.

And here it is obvious at once, that before any such reduction of the general laws of these syllogisms can take place, the special laws which govern particular classes of such syllogisms must be dealt

with. In fact, the condition of the possibility of any such reduction of the general laws is the annihilation of the special laws. Whatever, therefore, tends to effect the abolition of these special laws, (laws of the several figures, to wit,) tends directly to facilitate that simplification of syllogistic law which emerges in the single canon. The principle of a quantified predicate directly contributes to accomplish this, by proving the falsity and uselessness of these special rules.

For example, the laws of the *first figure* are—*that the sumption be universal, and—that the subsumption be affirmative.* Quantify the predicate, however, and neither of these laws hold.

First rule falsified.

Some men are some fleet-footed.
All rational is all man.
Some rational is some fleet-footed.

Second rule falsified.

All idealists are some philosophers.
No sensualist is any idealist.
No sensualist is some philosopher.

The laws of *the second figure* are—*that one of the premises be negative, and—that the sumption be universal.* To these the principle of a quantified predicate immediately applies, and falsifies them—

First rule falsified.

All risible is all man.
All philosophers are some men.
All philosophers are some risible.

Second rule falsified.

Some mortal is all man.
All rational is all man.
All rational is some mortal.

These examples may serve to illustrate specially the influence which the principle of a quantified predicate has upon these laws. It is to be remarked, however, generally, that these laws exist only in consequence of a defective logical analysis, and apply only to such an imperfection. When the analysis, therefore, is complete, these laws naturally fall away as henceforth useless and inapplicable. The recognition of a quantified predicate and of the true nature of figure renders this analysis complete. Thus the principle of a quantified predicate co-operating with the true doctrine of figure, sweeps away for ever from logic, as an encumbrance, all these special laws. The special laws being swept aside, the way is prepared for the reduction of the general. And this reduction effected, there emerges the supreme canon as given above. This canon, it is obvious, may be again easily evolved into those general laws of which it is the compend. We may take as an example the two most general laws of categorical syllogisms.

1. *That both premises be not negative.* This is expressed in the canon by the clause—" With which both are related, *and one at least positively so.*"

2. *That the middle term be distributed in one at least of the premises; and it is of no consequence*

whether it be distributed as the subject or the predicate.

The first part of this law is expressed in the canon by the clause—"*related to a common middle term.*" If it be common to both it must be distributed. The latter part of the law is expressed in the clause—"What worse relation of subject and predicate subsists between *either of two terms and a common third term.*" The common third term may thus be related to the two other terms either as subject or predicate.

It would be by no means difficult to evolve in the same manner the canon into the six more general syllogistic laws commonly given by logicians. The relation of these laws to the different clauses of the supreme canon is, however, manifest, and therefore need not be formally evolved here.

We pass on, then, to consider this canon in another aspect. We said that it determined every kind of categorical syllogism.

We shall endeavour to illustrate this;—

1. *Syllogisms differ with respect to the wholes in which they proceed.*

We have already said that all reasoning (deductive, that is, to which, when not otherwise specified, we always refer when speaking of reasoning in general) is from whole to part; but as there are two kinds of logical wholes and parts, there will naturally be two kinds of reasoning, corresponding severally to these different quantities. These wholes are—the *meta-*

physical or comprehensive whole; and the *logical or extensive* whole. A syllogism proceeding in the former is a comprehensive syllogism, in the conclusion of which the subject is the greatest whole, and the predicate the smallest part. A syllogism proceeding in the latter whole is an extensive syllogism, in the conclusion of which the subject is the smallest part, and the predicate the greatest whole. These different kinds of syllogism, distinguished by the different kinds of wholes in which they proceed, are determined by the first clause of the canon—"*What worse relation of subject and predicate subsists between two terms,*" &c. In the whole of comprehension the predicate is worse than the subject, since it is a part in relation to a whole; in the counter whole of extension, the subject is worse than the predicate, since in this quantity the predicate has become the greatest whole, and the subject the smallest part.

2. *Syllogisms differ with respect to figure.*

The variation of figure arises, as we have seen, from the various positions of the middle term in relation to the extremes. This variation is evidently determined in the canon by the clause—"*What relation subsists between either of two terms and a common third term.*"

But here it is necessary to go somewhat more fully into detail. We shall therefore return to the canon presently.

In considering figure somewhat more closely, we shall notice;—

a. The true nature of the figures.

We have seen that the figures, strictly so called, are regarded by logicians as true and original variations of the syllogistic form. We have seen also some of the inconsistencies which such a doctrine involves: enough certainly to beget a suspicion that it could not be the true one. We were thus led to suppose that there must be some confusion or complexity in the figures which it is necessary to remove before the true form of their reasonings could be seen in its ultimate purity and exactness. What this confusion or complexity is, we now proceed explicitly to show, by stating and illustrating the true nature of the figures.*

"The figures (strictly so called) are hybrid or mixed reasonings, in which the steps of the process are only partially expressed; the unexpressed steps are, in general, only conversive inferences which we are entitled to make from those that are expressed."

This being the nature of figure, it follows that, since all the real steps of the process are not expressed in the reasonings, the conclusion does not of necessity follow from the expressed premises; but the mind at once inferring and interpolating the wanting steps of the process, the conclusion follows in virtue of such inference and interpolation. When this mental interpolation is recognised, and the real premise which it constitutes is expressed, the syllogism emerges in

* Touching the value and history of this exposition, see the Appendix.

its simple form, and is at once recognised to be (through all the variations of mood and figure, strictly so called) a syllogism of the first figure. All such varieties are therefore thus shown to be, in their complex state, only unessential variations of that figure. We shall illustrate this in concrete examples through the moods of the second and third figures.

The moods of the second figure are—*Cesare, Camestres, Festino, Baroco.*

A syllogism in Cesare is—

No unreflective man is a philosopher.
All idealists are philosophers.
No idealist is unreflective.

By conversive inference we obtain as the real sumption, "no philosopher is unreflective," and this interposed in the place of the ostensible sumption, produces a syllogism in *Celarent* of the first figure, *e.g.*,—

No philosopher is unreflective.
All idealists are philosophers.
No idealist is unreflective.

A syllogism in Camestres is—

All animals are sentient.
Nothing unorganised is sentient.
Nothing unorganised is animal.

We have already said, when speaking generally of figure, that the premises are in this syllogism transposed; and that but for such transposition it is exactly the same as *Cesare;* reversing the premises then, and

dealing with it in the same manner as the last, it appears in the same form as *Celarent* of the first figure.

Nothing sentient is unorganised.
All animals are sentient.
No animal is unorganised.

A syllogism in Festino is—

No truly wise men go to extremes.
Some truly religious men go to extremes.
Some truly religious men are not truly wise men.

Here with the sumption converted the syllogism appears as *Ferio* of the first.

None who go to extremes are truly wise.
Some truly religious men go to extremes.
Some truly religious men are not truly wise.

A syllogism in Baroco is—*

All lilies are fragrant.
Some flowers are not fragrant.
Some flowers are not lilies.

Here the subsumption is to be dealt with; and by conversive influence we obtain "*some things not fragrant are flowers.*" Interpolating this, we have a syllogism in *Darii* of the first.

* [The reduction of this mood was one of the standard difficulties of the logicians. It could only at best be done with difficulty, and through the clumsy process designated *ad impossibile;* nor does it accommodate itself well to this expository process of Kant's; since after all it appears as a syllogism of the *fourth* figure rather than of the *first.*]

All lilies are fragrant.
Some things not fragrant are flowers.
Some things not lilies are flowers.

The *third* figure.

We have seen, in removing the complexity of syllogisms in the second figure, that it is the sumption for the most part (that is in three out of four moods) which is affected by conversive inference; and that that inference is made chiefly from "the absolute negation of the first notion as predicate of the second, to the absolute negation of the second notion as predicate of the first." In the third figure, on the other hand, it is the subsumption which is chiefly affected by conversive inference, and that inference is generally made "from the total or partial affirmation of a lesser notion of a greater, to the partial affirmation of the greater notion of the lesser."

The moods of the third figure are—*Darapti, Felapton, Disamis, Datisi, Bocardo, Ferison.*

A syllogism in Darapti is—

Every good man is happy.
Every good man fights with himself.
Some who fight with themselves are happy.

By conversive inference we here obtain as subsumption—"*some who fight with themselves are good men;*" and the syllogism is then in *Darii* of the first figure.

Every good man is happy.
Some who fight with themselves are good men.
Some who fight with themselves are happy.

A syllogism in the second mood Felapton is—

No man is winged.
All men are bipeds.
Some bipeds are not winged.

By converting the subsumption it becomes *Ferio* of the first.

No man is winged.
Some bipeds are men.
Some bipeds are not winged.

A syllogism in the third mood Disamis is—

Some patriots are persecuted.
Every patriot is brave.
Some that are brave are persecuted.

Here the premises are first to be transposed, then converting the subsumption the syllogism appears as *Darii* of the first—

Every patriot is brave.
Some that are persecuted are patriots.
Some that are persecuted are brave.

With respect to the fourth mood in the figure, *Datisi*, we have already shown that it differs from the third only in the transposition of its premises. Converting the subsumption, therefore, it appears in the same form as *Darii* of the first. We give the syllogisms together—

All true philosophers are truly noble.
Some true philosophers are despised.
Some that are truly noble are despised.

All true philosophers are truly noble.
Some that are despised are true philosophers.
Some that are despised are truly noble.

A syllogism in the fifth mood Bocardo is—

Some poets are not philosophers.
All poets have genius.
Some who have genius are not philosophers.

The premises are here transposed, and the sumption converted—it then appears as *Darii*—

All poets have genius.
Some not philosophers are poets.
Some not philosophers have genius.

A syllogism in the last mood Ferison is—

No hope is unattended with pleasure.
Some hopes are delusive.
Some delusive things are attended with pleasure.

Converting the sumption it becomes *Ferio* of the first—

No hope is without pleasure.
Some delusive things are hopes.
Some delusive things are attended with pleasure.

The syllogisms of the figures, strictly so called, are thus shown to be complex reasonings, which, when cleared of their complexity, and simply expressed, *i.e.*, expressed in that form which all true reasonings must ultimately assume, in which the least part or whole is subordinated to the greatest part or whole, through a lesser part or whole—appear in their true character as syllogisms of the first figure.

We have here taken no notice of the fourth figure, not because the same process of simplification is not equally applicable to its reasonings, as to those of the second and third figures ; but because, as we shall presently explain, we do not consider it properly a figure at all.

b. The true number of the figures.

We have seen that in the common doctrine four figures are recognised as valid.* The fourth figure

* [The validity of the *fourth* figure as a separate form of reasoning has been often contested, but that of the other three has remained for the most part unassailed. The *third*, however, has not wholly escaped assault. It was rejected by Laurentius Valla on the ground that such a form of reasoning was never used, that there are no examples of it to be found, and as it would seem, as much as for any other reason, because it offended his eye or ear. He does not, indeed, so much reason seriously against its validity, but rather denounces it at once, and that, too, in the most lively and rhetorical manner, as in the last degree preposterous and absurd. The whole style of the rejection is quite in harmony with his wayward originality and independence, as well as with his habit of rash yet fastidious criticism. It is, indeed, but another instance of the fastidious taste of Valla, in whose eyes a sin against purity of style was a moral offence of the gravest kind, who did not scruple to correct the Latinity of Cicero, and of whose criticism it is said the Devil himself stood in such awe, that he was afraid to speak in his presence, being nervous as to the classic purity of his Latin style.

The objections of Valla to the third figure were rebutted by Lazarus Schonerus, (as quoted by Fraunce,) who adduced examples of its use from Cicero and Virgil. Its validity and usefulness were also defended against Valla by Melanchthon, who, referring to it, says, " Laurentius Valla non leviter stomachatur hoc loco, et Aristotelem tanquam capitali judicio accusat, qui hanc figuram tradiderit. Sed Valla dum nullum rixandi finem facit, sæpe etiam incurrit, ut sit ab iracundis, in illos qui nihil peccaverunt. Mihi non tam plumbeo ingenio Aris-

was, however, introduced into the science later; and when introduced obtained a footing less secure than the other three. Some logicians, indeed, have omitted it altogether; while others have expressly redargued its claim to be admitted as a true schematic difference. The reasons of those who opposed its admission have not, however, proved sufficiently strong to eject it finally from the science, since it reappears in the latest systems, and is recognised as logically competent. It is, nevertheless, to be rejected from logic, as being utterly deformed and useless. *Deformed*, since its premises proceed in the whole of comprehension, and its conclusion in the counter whole of extension. *Useless*, since the reasoning in both these wholes is scientifically complete without it. The fourth figure being thus rejected, the three first alone remain. These, therefore, are to be considered as exclusively competent in logic.

c. The true canons of the figures.

We have said that the syllogistic difference of

toteles fuisse videtur, ut nulla de causa tertiam figuram tradiderit. Est enim reperire exempla ejus figuræ, in quibus si mutes dispositionem medii, feceris totum syllogismum obscuriorem." (*Dialectica*. Paris, 1532, fol. 42.)

This extract is taken from Melanchthon's *second* logical work. His opinion in relation to this matter does not appear to have been always equally decided, since Melchior Adam says, (in his short life of him,) referring to it; "Edidit Philippus eodem anno (1520) primum sua Dialectica in quibus *tertiam figuram syllogismorum* neque recipit, neque rejicit; quam deinde iterata editione, an. 1528, admisit." (*Vitæ Germanorum Philosophorum*. Francof, 1706, p. 88).]

figure is determined in the supreme canon of syllogism by the clause, " What worse relation of subject and predicate subsists between either of two terms and a common third term," &c. It is obvious, that this clause determines figure; for the syllogistic difference of figure is discriminated by the position of the middle term in relation to the extremes; or in other words, by the " relation of subject and predicate subsisting between the two terms and a common third term."

But this clause not only determines the difference of figure, it also immediately determines all the possible varieties of such difference. For the relation of subject and predicate, subsisting between two terms and a common third term, must be either that in which the common third term is the subject of one and the predicate of the other, or that in which it is the predicate of both, or that in which it is the subject of both. No other is possible. Now, these three possible variations of relation determine at once the number of the figures and the canons by which they are regulated. For the number of different figures can only answer to the number of different relations; and the evolution of these different relations in detail will be the expression of the laws by which the figures thus discriminated are severally governed.

These relations are—

I. *That in which the common third term is the*

subject of one of the terms, and the predicate of the other.

This constitutes the first figure alike in extension and comprehension.

First in Extension.

B is A
C is B
C is A

Here B, the third term, is the subject of (that is to say, contained *under*) A, the one term; and the predicate of (that is to say, contains *under* it) C, the other term.

So in Comprehension.

C is B
B is A
C is A

Here B, the middle term, is the predicate of (that is to say, comprehended *in*) C, the one term; and the subject of (that is to say, comprehends *in* it) A, the other term.

The canon of this figure is—"In so far as two notions or terms are related, either both positively, or one positively and the other negatively, to a common third term, of which the one is subject and the other predicate,—these two notions are related positively or negatively to each other as subject and predicate."

II. *That in which the common third term is the predicate of both the other terms.*

This constitutes the second figure, and that (contrary to the logicians) is either of affirmative or of negative syllogisms.

Affirmative.	*Negative.*
All A is all B.	All A is all B.
All C is some B.	No C is any B.
All C is some A.	No C is any A.

The canon of this figure is—" In so far as two terms or notions, both subjects, are either both positively, or the one positively and the other negatively, related to a common predicate,—in so far are they either positively or negatively subject and predicate, and that indifferently of each other."

III. *That in which the third term is the subject of both the other terms.*

This constitutes the third figure, and that (also contrary to the logicians) in syllogisms with either universal or particular conclusions.

Universal.	*Particular.*
All B is some A.	All B is all A.
All B is all C.	Some B is some C.
All C is some A.	Some C is some A.

The canon of this figure is—" In so far as two notions or terms, both predicates, are either each positively, or the one positively and the other negatively, related to a common subject,—in so far are they positively or negatively subject and predicate, and this indifferently of each other."

The relation of the middle term in the second and third figures explains how it is that these figures have no determinate major or minor premise, and two in-

different conclusions. There can be no determinate major or minor premise; *for a determinate major premise* is one in which the middle term is compared with the greatest notion, and determined by it; *a determinate minor premise,* one in which the middle term is compared with the smallest notion, and determines it. The middle notion thus always is in the former *determined,* in the latter *determining.* Now, in the second and third figures there can be no such relation of determination. In one the middle term determines both the premises, in the other it is determined by both. Hence, since there is no determinate major or minor premise, it is manifest that we may have two indifferent conclusions; for we may, in the second figure, indifferently predicate one subject of the other, and in third the one predicate of the other.

In the first figure, again, it is equally clear that there is such a relation of determination. In it the reasoning is perfect, proceeding from the largest whole through a lesser whole to the least whole. The first figure accordingly has a determinate major and minor premise, and one immediate conclusion.

d. The true relations of the figures.

We have already spoken of the two wholes in which reasoning proceeds—the whole of comprehension and that of extension—the characteristic of the former being that the predicate is contained *in the subject,* of the latter that the subject is contained *under the predicate.* This being remembered, it will appear that in

the second figure, where the middle term as predicate contains both the subjects *under it*, *extension* will predominate. In the third, where the middle term as subject is contained under, and therefore *comprehends in* it both the predicates, *comprehension* will prevail. In the first figure, again, where the middle term is both subject and predicate, extension and comprehension balance each other. The first figure is indifferently competent to either.

Reasoning, however, proceeds not only in different wholes, but in different *aspects* of the same whole. We may, it is evident, regard any whole, considered as the complement of its parts, in either of two ways; for we may, on the one hand, look from the whole to the parts, and reason accordingly downwards; or, on the other hand, look from the parts to the whole they constitute, and reason accordingly upwards. The former of these reasonings is called *deductive*, the latter *inductive*. *Deductive* reasoning is founded on the maxim—"What belongs to the containing whole belongs also to the contained parts:" *Induction* on the contrary maxim—"What belongs to the constituent parts belongs also to the constituted whole." Thus in deductive reasoning the whole is stated first, and what is affirmed of it is affirmed of the parts it contains; in other words, a general law is laid down, and predicated of the particular instances to which it applies. In inductive reasoning the parts are first stated, and what is predicated of them is also predi-

cated of the whole they constitute ; in other words, the particular instances are first stated as facts, and then the law they constitute is evolved.

This being the nature of these counter and correlative reasonings, it appears to us, that though each kind is competent in either whole, (extension or comprehension,) yet that the reasoning in the whole of extension is more naturally allied to the *deductive*, and that in comprehension to the *inductive*. For, in the whole of extension, the reasoning proceeds from the general to the special—from the abstract to the concrete—from general laws to the particular instances which are contained under them ; while in that of comprehension, on the other hand, the reasoning proceeds from the special to the general—from the concrete to the abstract—from the particular instances to the general laws, whose operation they exemplify.

The special adaptation of comprehension for inductive, and of extension for deductive reasoning, might be illustrated more fully in detail, and on other grounds ; but it may perhaps suffice to have indicated the relation between the two kinds of reasoning, and the two counter wholes in which they proceed.

Considering these kinds of reasoning in relation to the figures, it will appear, then, that since extension prevails in the second, that will be so far more suitable for deductive reasoning ; and since comprehension prevails in the third, that figure will so far be more

adapted for inductive reasoning; while, since extension and comprehension prevail equally in the first, that figure will be equally fitted for either kind of reasoning.*

* [The relation of the figures to these different kinds of reasoning will be best illustrated by an example. We will take first the second figure:—

Deductive reasoning: Quantity of extension.

Fig. II.
Endowed with reason is all man.
European, Asiatic, African, American, are all man.
European, Asiatic, African, American, are endowed with reason.

Here the reasoning is *deductive*, for the law is first enounced, the individual instances are next brought under it, and it is then affirmed of them; it is *extensive*, for it proceeds from the wider notion through the narrower to the individual. Let us now take the same terms and treat them inductively, beginning with the individuals. The reasoning will then be in the whole of comprehension, and will naturally appear in the form of the third figure:—

Inductive reasoning: Quantity of comprehension.

Fig. III.
European, Asiatic, African, American, are all man.
European, Asiatic, African, American, are endowed with reason.
Endowed with reason is all man.

Here the reasoning is *inductive*, for beginning with the individuals in the premises, we arrive at the law (with which we started in the previous syllogism) in the conclusion; it is *comprehensive* or *intensive*, for it proceeds from the concrete to the abstract, from a greater totality of attribute to a less. In other words, in either quantity (extensive or intensive) we reason from the greatest whole; but in the quantity of extension the greatest whole is the most abstract notion, (*i.e.*, the widest law,) whereas in that of comprehension, the greatest whole is the most concrete notion, (*i.e.*, the individual instance.) But proceeding thus from the widest law the reasoning is necessary deductive, while on the other hand, proceeding from the individual instance, it is as necessarily inductive.

The second and third figures are indeed naturally respectively connected with deductive and inductive

We may give the same example in the first figure, to illustrate (what will now be quite obvious) that it is indifferently competent to either reasoning :—

Fig. I.

Deductive reasoning : Quantity of extension.

All man is endowed with reason.
European, Asiatic, African, American, are all man.
European, Asiatic, African, American, are endowed with reason.

Inductive reasoning : Quantity of comprehension.

European, Asiatic, African, American, are all man.
All man is endowed with reason.
European, Asiatic, African, American, are endowed with reason.

I need scarcely say, that at the time of writing the essay, I was quite unaware that any of these special relations of the figures had been noticed by logicians. I find, however, that Wilson, in his "*Rule of Reason,*" (1580,) has, among other remarks tracing the use of the figures, the following :—"*Use of the third figure:* This figure profiteth much in provoking particular things, and gathering of conjectures in causes that are doubtful, when probability only, and no assured knowledge, boulteth out the truth of a matter. And because several things (individuals) come sonest to our senses, we use suche gathering moste commonly, and by triall of particular causes, assure ourselves of the truthe generally." Again, "when we make an argument and procede from the general word (genus) to the kind (species), it is in the first figure, and even by our reason we learn this, that if the greater bee not, the lesse cannot bee."

"When we procede from the kinde to the general, making the conclusion particular, the argument is in the third figure. And this is for ever true, that when the kinde is rehearsed, the generall must needes followe." (Fol. 30-1.) This, however, is little beyond a more explicit statement of what is commonly said of the third figure, that it is a reasoning from the special.]

reasoning ; for in the second we judge the likeness or unlikeness of two parts, as they are contained or not contained by a common whole ; while in the third we judge the likeness or unlikeness of two wholes, as they severally contain or do not contain common parts.

3. *Syllogisms differ with respect to mood.*

The syllogistic variety of mood arises from the different quality and quantity of propositions, and this difference is determined by the supreme canon in the clause—" *What worse relation of subject and predicate,*" &c., since a negative quality is a worse relation than a positive, and a particular quantity a worse relation than a universal.

Logicians, however, in their enumeration of moods, as we have seen, have taken into account only one quantity of propositions ; have considered the subject as quantified to the exclusion of the predicate ; and have, in so doing, deformed their science by excluding from it many valid forms of reasoning—forms which logic, if it be an exact science, and its analysis of the form of thought exhaustive, is bound to recognise and vindicate as valid.

It is the design of the "new analytic" that its analysis shall be thus exhaustive ; and it vindicates its title by discovering and developing, in its various relations, an element of formal thought which had remained undeveloped, if not unrecognised, in every previous analysis. That element is, as we have

said, the express quantification of the predicate, the true application of which recalls to the science many true forms of reasoning, the date of whose logical proscription may be reckoned as coeval with that of the science itself.

We shall proceed briefly to vindicate these forms. Logicians, combining the quality of a proposition with the quantity of its subject, reckon in all four kinds of propositions; and combining these propositions in every possible way, evolve sixty-four moods. But it is clear, that if the quantity of the predicate be taken into account, the various kinds of propositions discriminated by quantity and quality will be doubled in number, and a proportionate increase effected in the number of possible moods; for we shall now have eight kinds of propositions, viz., four affirmative :—

Definite, affirmative, definite.
Definite, affirmative, indefinite.
Indefinite, affirmative, definite.
Indefinite, affirmative, indefinite.

And in the same manner, four negative propositions. With this increase in the number of propositions, we need new symbols by which to designate them. We may, however, still retain the old notation A. I. E. O., and express the new forms by combining the letters into diphthongs, or placing them within brackets, as occasion may require; *e.g.*,—

Definite, affirmative, indefinite = (AI.)
Indefinite, negative, definite = Œ, &c.

This increase in the number of propositions to be combined effects of course a great increase in the number of moods resulting from such combination. Of the possible moods thus given, a number are invalidated by the clause of the canon, "*one at least positively so,*" from having two negative premises. A number more are excluded by the clause, "*a common third term,*" from the middle term being undistributed. Throwing these out of account, together with some others having particular conclusions where universal are competent, *there remain in all thirty-six valid moods,* (twelve affirmative and twenty-four negative,) and these thirty-six are valid in each figure.

We employ the symbolical notation,* using the comma (,) to denote "some," (indefinite quantity,) and the colon (:) to denote "all," (definite quantity).

Valid moods of the first figure.

	Affirmative.	Negative.
i.	A : — : B : — : C	1. A : + : B : — : C 2. A : — : B : + : C
ii.	A , — : B : — , C	1. A , + : B : — , C 2. A , — : B : + , C
iii.	A : — : B : — , C	1. A : + : B : — , C 2. A : — : B : + , C

* On this system of notation, see the Appendix.

v. A : —— : B , —— : C { 1. A : —+— : B , —— : C ; 2. A : —— : B , —+— : C

vi. A : —— , B : —— : C { 1. A : —+— , B : —— : C ; 2. A : —— , B : —+— : C

vii. A , —— : B , —— , C { 1. A , —+— : B , —— , C ; 2. A , —— : B , —+— , C

viii. A , —— , B : —— , C { 1. A , —+— , B : —— , C ; 2. A , —— , B : —+— , C

ix. A : —— : B , —— , C { 1. A : —+— : B , —— , C ; 2. A : —— : B , —+— , C

x. A , —— , B : —— : C { 1. A , —+— , B : —— : C ; 2. A , —— , B : —+— : C

xi. A , —— : B , —— : C { 1. A , —+— : B , —— : C ; 2. A , —— : B , —+— : C

xii. A : —— , B : —— , C { 1. A : —+— , B : —— , C ; 2. A : —— , B : —+— , C

We have given the above syllogisms in the first figure; but they may all be easily translated into the two others.*

* [The only one of the prescribed requisites which the essay does

To recapitulate then. We set out with the principle of a quantified predicate. We have noticed some things by the way not immediately connected therewith; but recurring to it, we have endeavoured to vindicate that principle. We have indicated its influence on propositions in abolishing the complex doctrine of conversion; its influence on categorical syllogisms, in reducing their laws to a higher simplicity, and amplifying their valid forms,—in short, by correcting what was false, and supplying what was wanting; and thus, by securing to logic a higher degree of formal exactness, realising for it a higher degree of scientific perfection.

not to some extent attempt to meet, is that in which it is required "to show in concrete examples, through all the moods, the unessential variation which figure makes in a syllogism." This was omitted at the time of writing through haste; but it is so obvious, that with a little trouble, each reader may do it for himself. As an illustration, however, the following is a concrete example of the first mood, carried through all the figures:—

Fig. I.
All man is some animal.
Every Celt is some man.
Every Celt is some animal.

Fig. II.
Some animal is all man.
Every Celt is some man.
Every Celt is some animal.

Fig. III.
All man is some animal.
Some man is every Celt.
Some animal is every Celt.

Fig. IV.
Some animal is all man.
Some man is every Celt.
Some animal is every Celt.

The "*new analytic*" accomplishes this by being true to its office, and fully investigating the form of thought. *The form, the whole form, and nothing but the form of thought,* is indeed the bannered motto which it bears on its triumphant way. True to its purpose, it advances over the whole region of formal thought, conquering and to conquer; destroying the false landmarks which had been set up by the early discoverers of that territory; repressing the incursions which were continually made into neighbouring kingdoms; destroying the border ground by determining for ever the frontier line; dethroning the potentates who had intrenched themselves in its high places, and long there exercised a usurped authority; recalling from their long exile the true lords of the soil; re-establishing the laws on which their rights were founded, and enforcing strict obedience to these in every province of the empire. Thus, though in some respects its path is as the path of the destroyer, in a higher and truer sense it is the path of peace; for through its instrumentality there breaks at length upon this long distracted region the golden age of simplicity and order. And anarchy, the result of laws neglected and rights ignored, is for ever abolished in the establishment of perfect harmony—a harmony the result of law clearly expounded and rigidly obeyed throughout the entire empire of formal thought.

In conclusion, we are well aware of the very imperfect manner in which we have signalised those parts of the new discovery on which we have touched. We cannot, however, close without expressing the true joy we feel, (though, were the feeling less strong, we might shrink from the intrusion,) that in our country, and in our time, this discovery has been made. We rejoice to know that one has at length arisen, able to recognise and complete the plan of the mighty builder, Aristotle,—to lay the top-stone on that fabric, the foundations of which were laid more than two thousand years ago by the master hand of the Stagirite, which, after the labours of many generations of workmen, who have from time to time built up one part here and taken down another there—remains substantially as he left it; but which, when finished, shall be seen to be an edifice of wondrous beauty, harmony, and completeness.

APPENDIX.

No. I.

HISTORICAL NOTICE TOUCHING THE EXPLICIT QUANTIFICATION OF THE PREDICATE.

THE statement made in the first page of the Essay, that "the principle of a quantified predicate had, in its full scientific significance, been totally overlooked by logicians, and that, when noticed at all, it had, for the most part, been referred to only to be discarded as useless, if not to be condemned as false"—was made, it scarcely need be said, upon a very limited acquaintance with logical works. It was, however, the conclusion to which my inquiries, so far as they extended, led me. I had examined several logical treatises, and found that the majority made no reference at all to a quantified predicate, that the few who noticed it, (two of which are quoted,) treated it in the manner described in the text; while, so far as my reading extended, I had not found a single instance in which it was admitted in any form. Since writing the Essay, I have naturally been curious in my occasional logical reading to mark any references which might be made to this subject; and as the result of a somewhat fuller knowledge of the historical development of the science, I am able to establish, upon somewhat wider evidence, the general truth of the statement made in the text. The full scientific significance of the principle certainly never has been appreciated. It has been, "for the most part, rejected;" that is to say, it has been denounced by the vast majority of logicians as

useless and false. Some exceptions, however, to this summary rejection of the principle are to be found. A few of these I have met with, some of which as in themselves curious, and as lying out of the way of ordinary reading, it may be worth while explicitly to notice. In order, therefore, to place the Essay on a level with my present knowledge, I shall briefly establish historically the common rejection of the principle of a quantified predicate, and then notice some of the exceptions to this treatment of it which are to be found.

I. *The common doctrine which altogether rejects the express quantification of the predicate.*

This doctrine dates substantially, as do most logical truths and heresies, from Aristotle. He refers explicitly in two places*—in his *Book on the Doctrine of Enunciation*, and in his *Prior Analytics*—to the quantification of the predicate, and in both rejects it in a very summary manner. In the Book touching Enunciation he says,—"Ἐπὶ δὲ τοῦ κατηγορουμένου καθόλου τὸ καθόλου κατηγορεῖν, οὐκ ἔστιν ἀθηλές· οὐδεμία γὰρ κατάφασις ἀληθὴς ἔσται, ἐν ᾗ τοῦ κατηγορουμένου καθόλου τὸ καθόλου κατηγορεῖται οἷον ἔστι πᾶς ἄνθρωπος πᾶν ζῶον." (*De Enunciandi Ratione*, c. vii. § 4.) The parallel passage in the *Prior Analytics* is as follows: "Αὐτὸ δὲ τὸ ἐπόμενον οὐ ληπτέον ὅλον ἔπεσθαι· λέγω δ', οἷον ἀνθρώπῳ πᾶν ζῶον, ἢ μουσικῇ πᾶσαν ἐπιστήμην· ἀλλ' ἁπλῶς μόνον ἀκολουθεῖν, καθάπερ καὶ προτεινόμεθα· καὶ γὰρ ἄχρηστον θάτερον, καὶ ἀδύνατον, οἷον πάντα ἄνθρωπον εἶναι πᾶν ζῶον· ἢ δικαιοσύνην ἅπαν ἀγαθόν." (*Anal. Pri.* i. c. 27, § 9.) The quantification of the predicate is to be absolutely rejected; such is the judgment of Aristotle on the point.† That this judgment was given rashly and without

* Other references are made to the subject by Aristotle in the *Book of the Categories* and the *Posterior Analytics*; but the above are the most decisive passages.

† It is right to state, that the only case which is here explicitly contemplated by Aristotle, is that in which the predicate is quantified *universally*. His dictum, however, in relation to this is not true, since we may often

due consideration is, however, manifest, both from the fact that Aristotle himself explicitly quantifies the predicate in other parts of his writings, as also from the fact that his formal rejection of such quantification is unsupported by a single argument. All that is offered in its defence is an illustration so inept and one-sided, that its fallacy seems almost transparent. He says, in effect, that it is impossible to quantify the predicate, because it is false to say, *all man is all animal;* which is surely no better as an argument than it would be to say, that it is impossible to divide a foot into inches, because it is false to say that *one inch is a whole foot.* With the exception of this example, and one or two others of the same kind, Aristotle wisely abstains from offering any defence of his hasty judgment. His wisdom in this respect has not, however, been imitated by his followers, who have, in various ways, endeavoured to explain and defend the dictum of their master.

Passing over the Greek commentators, (with whose labours I am not sufficiently familiar to enable me to speak of them with confidence,) we come to the first, as in some respects he still remains the best Latin expositor of Aristotle—Boëthius. Boëthius flourished during the latter part of the fifth and the beginning of the sixth centuries. He translated all the books of the Organon, and wrote elaborate commentaries on more than one, besides furnishing other and more direct contributions to logical science in the form of original treatises. To his versions and commentaries the schoolmen were mainly indebted for their knowledge of Aristotle; and to these, accordingly, may be traced several of the particular interpretations which subsequently became current in the science, and were, indeed, for the most part authenticated as of Aristotelic origin. To determine, therefore, the opinion of Boëthius on any particular point,

quantify the predicate universally; but as he implicitly makes this case representative of the whole doctrine, it is obviously altogether false, since we may, and must always quantify the predicate *unirersally* or *particularly.*

is of some importance, as it will be often found to be that which subsequently prevailed.

He gives the point in question fuller consideration than it receives at the hands of Aristotle; but in his treatment of it, nevertheless, he confines himself to the same restricted aspect, and arrives substantially at the same one-sided conclusion. Considering exclusively the case in which the predicate is quantified *universally*, he proves triumphantly what seems to require really very little proof, that the genus cannot receive a mark of universal quantity when it is predicated of its species. Commenting on the passage already quoted from the Book touching *Enunciation*, he says as follows:—

"Quod dicit hujusmodi est:—Omnis propositio simplex duobus terminis constat, his sæpe additur aut *universalitatis* aut *particularitatis determinatio;* sed ad *quam partem* hæ determinationes addantur, exponit. Videtur enim Aristoteli, prædicato termino determinationem non oportere conjungi. In hac enim propositione, quæ est 'homo animal est,' quæritur—subjectumne debeat cum determinatione dici, ut sit 'omnis homo animal est;' an prædicatum, ut sit 'homo omne animal est;' an utrumque, ut sit 'omnis homo omne animal est.' *Sed neutrum eorum quæ posterius dicta sunt, fieri oportet; namque ad prædicatum nunquam determinatio jungitur, sed ad subjectum tantum.* Neque enim verum est dicere 'omne animal omnis homo est;' idcirco, quoniam *omnis prædicatio*, aut *major* est *subjecto*, aut *æqualis*. Ut in eo quod dicimus, 'omnis homo animal est,' plus est animal quam homo. Et rursus in eo quod dicimus, 'homo risibilis est,' risibile æquatur homini. Ut autem sit minus prædicatum atque angustius subjecto, fieri non potest. Ergo in *his predicatis* quæ subjecto *majora* sunt, ut in eo quod est animal, perspicue *falsa* est propositio, si determinatio universalitatis ad prædicatum terminum ponitur. Nam si dicamus, 'homo est animal,' animal, quod majus est homine, per hanc determinationem ad subjectum hominem usque contrahimus; cum non solum ad hominem, sed

ad alia quoque, nomen animalis possit aptari. Rursus, in iis quæ *æqualia* sunt, idem evenit. Nam si dicam, ‘ omnis homo omne risibile est,’ primum, si ad *humanitatem* ipsam referam, *superfluum est adjicere determinationem.* Quod si ad *singulos* quosquam hominum, *falsa* est propositio ; nam cum dico ‘ omnis homo omne risibile est,’ hoc videor significare, singuli homines omne risibile sunt, quod fieri non potest. *Non igitur ad prædicatum, sed ad subjectum determinatio ponenda.* Verba autem Aristotelis, hoc modo sunt, et ad hanc sententiam ducuntur :—‘ In his prædicatis quæ sunt universalia, his adjicere universale aliquid, ut universale prædicatum universaliter prædicatur, non est verum ;’ hoc enim est quod ait. In eo vero quod prædicatur universaliter, id est, quod habet prædicatum universale, ipsum universale prædicatum [prædicare] universaliter, non est verum. In prædicato enim universali, id est, quod universale est et prædicatur, ipsum prædicatum, quod universale est, universaliter prædicare, id est, *adjecta determinatione universalitatis, non est verum. Neque enim potest fieri, ut ulla sit affirmatio vera, in qua de universali prædicato universalis determinatio prædicetur ;* eisque rei notionem exemplo aperit, dicens, ‘ ut omnis homo omne animal est ;’ hoc autem quam sit inconveniens, supra jam diximus.” (*Opera Omnia. Basil.*, pp. 348, 349.)

In the opening sentence of this (corrected) extract Boëthius states the question fairly, and looks at it from a higher point of view than that in which it had been considered by Aristotle. He begins by saying, that every simple proposition is composed of two terms, that to these a determination of *universality* or *particularity* is often added, and then proceeds to inquire to which of the terms *these* determinations should be affixed. From this introduction it might reasonably have been inferred that the question would be discussed on broader grounds than those on which it had previously been treated, and that quantification in relation to the predicate would be considered in its generic latitude, and not in one of its species alone. This expectation is,

however, as we have said, not fulfilled; for immediately after having said that the terms receive marks of *universality* and *particularity*, and that the inquiry is, to which of the terms these marks should be appended, Boëthius proceeds to consider the mark of *universality* alone; and decides on this restricted consideration of the matter, that the marks of quantity are to be affixed exclusively to the subject, and never to the predicate.

The whole passage is, however, curious and valuable, not only in itself, but also in its historic relation, from its having (as already hinted) determined in effect nearly all that was subsequently said by others on the subject. There is not, I think, in all the subsequent refutations of a quantified predicate which have been attempted, a single argument which is not substantially contained in this quotation.

The next name of authority after Boëthius is that of the Arabian Averroes, who, from the extent and value of his labours, as expositor of Aristotle, was called *The Commentator*, κατ' ἐξοχήν. He flourished in the twelfth century, and by his almost incredible devotion to Aristotle, and his unwearied zeal in expounding and epitomising his works, contributed not a little to promote the complete ascendency which the peripatetic philosophy subsequently obtained.

Averroes treats the point in question with much greater brevity than Boëthius, but arrives at precisely the same conclusion.

In his commentary on the passage in the *Book of Enunciation*, he says, "Et non dividuntur enunciationes ex parte conjunctionis clausuræ cum prædicato; quia, clausura cum *adjungitur prædicato*, est *falsa* enunciatio, aut *superflua;* et falsa quidem est, 'omnis homo est omne animal;' superflua sicut cum diximus, '*omnis homo est quoddam animal.*'" (*Averrois Opera omnia.* Venet. 1560. Tom. i. fol. 45.) He has another sentence to the same effect in his commentary on the twenty-seventh chapter of the first book of the *Prior Analytics.* It is as follows—"Oportet

ut sepimentum (hoc est determinatio) semper coaptetur subjecto propositionis acceptæ, *non autem prædicato*, quoniam si conjungetur prædicato, erit aut *impossibilis*, aut *inutilis* ad syllogismum, secundum quod declaratum fuit in libro præcedente." Fol. 118.

The first of these extracts from Averroes, though so brief, is curious, inasmuch as he there explicitly takes account of what is not noticed by Aristotle or Boëthius before him, or, as far as I remember, by any of the rejectors of a quantified predicate after him,—the case, to wit, in which the predicate is quantified *particularly*. He considers, with Aristotle, first, the case in which it is quantified *universally*, " all man is all animal," and, with him, rejects this as false and impossible. He then proceeds to consider the case in which it is quantified *particularly*, " all man is *some* animal;" here he was free to act as he would, for of this second case nothing had been said; but the spell of Aristotle's rejection of the universal quantification was still strong upon him, and accordingly he rejects the *particular* also as *superfluous* and *useless*. The grounds of this rejection are, it need scarcely be said, totally extra-logical; for the particular quantification of the predicate in the given example is *superfluous* only by an appeal to the *matter of the proposition*, with which logic has nothing whatever to do; and so far from being *useless*, such quantification is *absolutely necessary*, before the predicate notion, as the constituent of a reasoning, can be turned to its full scientific account.

From Boëthius and Averroes, the logical treatises of Aristotle, with the traditions founded upon them, passed, as we have said, to the schoolmen; among these Albertus Magnus and St. Thomas Aquinas are quoted as having anew defended the rejection of a quantified predicate. The hereditary confession of logical faith, now become venerable through constant subscription, passed from the schoolmen to the later commentators on the Organon. These, while throwing off, to a great extent, the formality of the scholastic style, are yet rarely wise in im-

portant points above the teaching of their masters. On the point in question, that of a quantified predicate, they seem to have remained, with scarcely an exception, faithful to the received traditions. In illustration of this we will take two, which are among the best and most valuable of the later commentaries on the Organon, that of *Julius Pacius*, and that of the *College of the Society of Jesus at Coimbra.*

Julius Pacius, the pupil of Zabarella, and preceptor in philosophy of Casaubon, was both a very learned and a very acute man; and his works accordingly exhibit the accuracy and penetration resulting from these blended excellencies. His commentary on the Organon was first published in the year 1597. It was so full, clear, and precise, and altogether such a useful book, that it speedily attained a high reputation, and has ever since maintained its place as a standard work on the Organon. Pacius discusses the question of a quantified predicate in connexion with both the passages which we have quoted from the Organon; and as his opinion in this matter stands in much the same relation to the later philosophy as that of Boëthius did to the earlier, it may be worth while to quote it in full. The more so, too, as it is in itself the fullest discussion of the matter probably to be found among the later writers.

The first passage is from his Commentary on the *Book of Enunciation;* it is as follows :—

" In duabus primis particulis sejunxerat indefinitas ab universalibus; quoniam universales subjecto universali addunt notam universalem *omnis*, vel *nullus;* indefinitæ verò nullam notam subjecto apponunt. Unde potuisset aliquis suspicari tale discrimen, quod modò exposuimus in subjecto, nempe recipere notam universalem, aut eâ notâ carere, tale (inquam) discrimen etiam in attributo spectari posse; quasi vel simpliciter proponi possit, vel cum nota universali. Hunc errorem ut Aristoteles tollat, ostendit *universalem notam nunquam posse adjungi attributo :* quia tunc omnis affirmatio *falsa* esset.

Quod declarat exemplo hujus enunciationis, 'omnis homo est omne animal,' quæ sine dubio falsa est: nam si homo esset omne animal, esset etiam asinus et bos. Sed notare hic oportet, alia attributa latius patere quam subjecta, alia verò reciprocari cum subjectis. Hoc est quod dicebat Porphyrius, cap. 2, pars 37, aut majora de minoribus aut æqualia de æqualibus dici. Ubi igitur attributum latius patet, ut in exemplo Aristotelis, res dubitatione caret: certum enim est, affirmationem esse falsam, nec posse dici, 'omnem hominem esse omne animal.' Sed meritò dubitatur de attributis, quæ reciprocantur cum subjectis, veluti si quis dicat, 'omne animal est omne sensu præditum,' et 'omnis homo est omne aptum ad ridendum:' nam hic absurditas illa non æquè apparet, ut in illa enunciatione, 'omnis homo est omne animal.' Sed ut intelligatur has quoque enunciationes esse falsas, in quibus attributum, quod reciprocatur, adnexam habet particulam *omnis*, notare oportet, hanc particulam *omnis*, habere vim quam in scholis vocant distributivam; ut omnis homo, proinde valeat atque quilibet homo, vel *singuli homines;* et similiter omne animal, idem valet, quod singula animalia, vel unumquodque animal seu quodlibet animal. Quapropter si verè diceretur, 'omne animal est omne sensu præditum,' etiam homo esset omne sensu præditum; nam qui dixit omne animal, non exclusit omnem hominem, homo igitur esset quodlibet sensu præditum: proinde hac ratione fieret, ut homo esset equus, et bos, quandoquidem equus et bos sunt sensu prædita." (*Pacius in Aristotelis De Interpret.* cap. vii.)

The second passage is from the commentary on the *Prior Analytics*, and is as follows:—

"Quintum præceptum est, ne sumamus consequens, quod totam consequatur, sed quod toti sit consequens: id est, ut nota universalis *omnis* vel *omne*, jungatur subjecto, non attributo propositionis. Primò, Aristoteles proponit hoc præceptum. Deinde, cum ait, 'verbi gratiâ,' præceptum illud exemplis illustrat. Tertiò, cum ait, 'quonium alterum,' duplici argumento præcep-

tum illud confirmat. Primum est; quia si sumas id, quod totum consequitur, pars ejus erit inutilis, et ad rem non faciat. Alterum argumentum est; quia propositio erit impossibilis, id est, necessario falsa. Posterius argumentum declarat his exemplis, 'omnis homo est omne animal,' et 'justitia est omne bonum.' Nam hæ propositiones sunt evidenter falsæ, ut etiam expositum fuit *Capite* 7, *De Interp. Partic.* 4. Prius argumentum ab Aristotele non explicatur, ideoque a nobis est breviter explicandum. Ergo etiamsi verè dici possit, omnem hominem est omne animal; tamen illud *omne* nihil faceret ad concludendum problema; tantumdem enim valet hæc propositio, 'omnis homo est animal.' Exempli gratiâ, si probandum sit, omnem hominem, vivere; et primum, sumatur hæc propositio, 'omne animal vivit;' si addas assumptionem, quod 'omnis homo est animal,' etiamsi non sumas esse omne animal, tamen rectè colliges omnem hominem vivere. Postremo, cum ait, 'sed cui [aliud]' concludit universalem illam notam *omnis*, esse subjecto adjungendam." (*Pacius in Arist. Analyt. Pri.* i. cap. 27, § 9.)

The commentary on the Organon by the *College of Coimbra* was first published in the year 1600, a few years after that of Pacius. It was one of those able works on philosophy to which, after the decline of scholasticism, the zeal and energy of the Jesuits in letters and philosophy gave birth. It is far from being a mere slavish transcript from previous writers, but has on the contrary acuteness and originality enough to enable it to stand out in its individuality from the works of the time. In relation to the point in question it is, however, in harmony with its predecessors and contemporaries. The following is its deliverance on the matter:—

"Docuerat (Aristoteles) in propositionibus universalibus signa universalia addi subjecto, ambigeret quis, an prædicato etiam addi oporteret, ut quemadmodum dicimus, 'omnis homo est animal,' libeat ita loqui, 'omnis homo est omne animal:' respondet negativè in affirmativis, quia aliter *omnis affirmatio uni-*

versalis falsa esset, veluti si dicas, 'omnis homo est omne animal,' neque enim omne animal in homine est. Notanter, addit Aristoteles, nulla erit affirmatio vera, quia in quavis materia, etsi *prædicatum æquale* existat *subjecto*, propositio erit *falsa*. Nam sensus hujus propositionis, 'omnis homo est omne risible,' est quod *hic* homo est omne risible, et *ille* homo est omne risible, distribuit enim particula *omnis*, subjectum copulativè pro omnibus. Unde patet, quam errent Averroes et Boëthius existimantes addi posse signum universale prædicato, universalis propositionis, quando illud exæquat subjectum: nisi propositionis accipiant non copulativè præter earum usum et naturam. De *negativa propositione* nihil docet quia in ea, etsi negatio addi possit prædicato absque falsitate, superflua tamen est, quia virtute præcedentis negationis ad omnia extenditur prædicatum." (*Comment. Coll. Conimbr. in universam Dialecticam Aristotelis.* Colon., 1611. Pars ii. p. 158.)

I confess that Boëthius and Averroes appear to me to be but hardly treated in the above passage, in being held guilty of error for saying that the universal quantification of the predicate, when it was equal in extent to the subject, was simply superfluous, instead of denouncing it as false. Boëthius, indeed, as we have seen, hypothetically does the latter, but considers the whole case with far greater wisdom than his censor, since he says in relation to it, that the quantification is *superfluous*, if the subject be taken *collectively*, but *false* if it be taken *distributively*. With the exception of the admission that the predicate of a negative judgment may be quantified, without making the proposition false, the above extract is at one with the previous authorities.

Keckermann adds nothing new, save one example, (which is, however, something, where the whole question is solved by examples,) if possible, still more inept, not to say absurd, than the common ones. A number of other logical writers, about equal in authority to Keckermann, such as Burgersdyk,

Hereboord, Stahl,* Derodon, &c., might be referred to as giving deliverances to the same effect. There is nothing, however, in their statement of the common opinion that merits special attention, or that need be quoted here.

Such is the position which the opinion of the illegality of quantification in relation to the predicate has maintained in the history of the science. It has been held from the earliest to the latest times. Nor is it by any means yet obsolete. With the exception of the comparatively few quarters in which Sir W. Hamilton's refutation of the old, and application of the new doctrine, have become known, it is as firmly and as widely held today as it ever was. The marvellous acuteness of Kant, in relation to everything connected with formal thought, which did good service in other parts of logic, brought no help here. Nor has the newly-kindled zeal on behalf of Aristotle and his philosophy, manifested in Germany and France, been of any more avail. The last German editor of the Organon, Theo. Waitz, still says, on the classical passage in the Book of Enunciation,—"Quum additur 'omnis,' non id de quo prædicatur universale esse significatur, sed de re aliqua universa aliquid prædicari judicatur. Si vero quod prædicatur, quum universale est, universum prædicatur, *enunciatio exit non vera.*"—(*Aristotelis Organon, Edidit T. Waitz.* 1844. Pars i. p. 337.) Finally, the last French translator and expositor of Aristotle, M. J. B. Saint-Hilaire, in his excellent version of the Organon,

* Stahl and Derodon have been quoted already in the Essay. While referring again to Stahl, I may mention here what ought to have been stated in the note respecting him at page 2, viz., that in what he says of *comprehension* and *extension*, he but repeats Cajetanus, quoted, indeed, himself to the same effect earlier in his work. (*Reg. Phil.*, p. 381.) The work of Cajetanus on the categories from which Stahl quotes, dates from 1496, so that the discrimination of these quantities by the epithets *extensive* and *intensive* is of some antiquity. The term *intensive* was commonly employed in the Leibnitian school in the same sense, and was probably revived by Leibnitz, immediately from Cajetanus, or mediately through Stahl.

still reiterates, without a reason, in his notes, the rejection of the text:—" L'attribut n'a jamais la marque d'universalité : et l'on ne saurait dire : Tout homme est *tout* animal : on dit simplement et d'une manière absolue : Tout homme est animal. Le signe d'universalité n'est jamais qu' à l'antécédent, c'est-à-dire, au sujèt."—(*Logique d'Aristote, trad.* Paris, 1839. Tom. ii. p. 125.)

To sum up, then, the evidence we have obtained, the whole question, as commonly treated by the logicians, may be stated as follows:—The predicate, they consider, (with a single exception,) can only be quantified *universally*. Now, this being the only possibility contemplated, two cases arise ; for either, in the *first place*, the predicate is *greater* than the subject, and then such quantification is *false*, as "all man is all animal;" or it is *equal* to the subject, and then such quantification is *superfluous*, as " all man is all risible." The later commentators, however, are not satisfied with this comparatively mild dismissal of the second case, but maintain, that in *any case*, in the latter as well as in the former, the quantification is necessarily *false ;* and this on the apparently inconceivably inconsequent ground, that if *all man* is all risible, then necessarily *each man* is all risible ; or to take a parallel example, (one, however, which they do not take,) that if *twelve inches* are one foot, then necessarily *each individual inch* is also one foot.

When we consider these grounds, and remember the real ability of the men by whom they were successively urged, we cannot but be struck with a wonder amounting to marvel, that they could remain satisfied with them, and that a truth so obvious on its first enunciation, so imperative on its fuller exposition, should have been so uniformly and so long thus rejected. Allowing that the original judgment of Aristotle was given rashly upon but a partial consideration of the subject, we still cannot at all understand how his followers should not, on the one hand, having undertaken its examination, have discovered its fallacy,

or, on the other, having adopted and undertaken to defend it, have offered something better—something at least not absurd—in its vindication. It is, however, but another instance, perhaps the most illustrious of all, of what has been often noticed, of how completely the weight of authority often prevails against the clearest evidence. As in physical science the older philosophers refused to believe the evidence of their senses against the recorded judgment of Aristotle, so in mental science they refused to accept the equally obvious evidence of their understandings, where it testified against the same infallible authority.

The only explanation which can be offered of this strange oversight, and it is probably the true one, is, that the logicians for the most part (after Aristotle) limited their attention to the single case of universal quantification. This, considered in relation to the rules which were already laid down for predication, according to which the predicate notion was always of greater extent than the subject notion, would not only naturally, but necessarily lead to the rejection of such one-sided quantification.

Some exceptions do, however, as we have said, occur, in which the subject is looked at in a wider aspect, and to these it is time that we should more explicitly refer.

II. *Some exceptions to the common doctrine, in which the principle of a quantified predicate receives a more enlightened consideration, and is partially, either in principle or practice, formally allowed.*

Laurentius Valla was, so far as I know, the first by whom the express quantification of the predicate was in any form, or to any extent allowed. And if, indeed, the force of the tradition against it was ever to be broken through, this was a service which we might naturally have expected to receive at his hands, since he was assuredly one of the most independent and active thinkers, not alone of his own, but also of any age. The same

originality of which his life and writings were the constant expression, characterises also his logical inquiries. He complained of the diffuseness and defects of the existing logic, undertook a thorough examination of its doctrines, and accepted none but such as appeared founded on the truth of things. Whatever, therefore, rested simply on authority he at once threw aside, while whatever appeared to have scientific evidence in its favour he with equal readiness adopted. As the result of this thorough independence, he was doubtless sometimes led into error, from which an adherence to authority would have preserved him; but he was often also led into truth, to which the force of authority would as certainly have denied his access; so that on the whole he certainly introduced more truth than error into the science, and had he been less hasty and capricious, the result of his labours would probably have been still more valuable. As it is, however, his treatise has all the freshness and vigour of independent thought, and with no loss of accuracy, possesses the rare merit of being a really interesting introduction to a science not proverbial for the attractiveness of its elementary works.

Valla flourished during the first half of the fifteenth century, having been born at Rome in 1408, and dying in 1457. His logical work, *De Dialectica*, dates therefore from the middle of that century. I cannot find, however, any account of a printed edition of it before the one published at Venice in the year 1499, though in all probability it must have been printed much earlier. From the title of this earlier edition, "*De Dialectica contra Aristoteleos*," it would seem at first to have been avowedly published against the logicians of the day; as it is quite certain, from his short defence of himself at the close of the work, that Valla did not escape severe censure, and indeed persecution. The boldness of his criticisms on the current doctrines, indeed, (though these were coupled for the most part with the most respectful references to Aristotle himself,) when taken in connexion with the enmity aroused by his

stubborn adherence to the truths which he had obtained by his own industry, and his contemptuous rejection of those which were merely traditional;—his criticisms, we say, taken in connexion with the enmity which his conduct in these respects had excited, were likely enough to provoke active and fierce opposition. His attack (or what seemed an attack) upon the time-honoured and sacred fortress of the Aristotelic logic, would naturally be the signal for a general assault on the part of his enemies. There are none, however, but must be struck with the calm beauty and dignity of his protest against the meanness and the malice of the persecutions to which he had been subjected for his defence of what he held to be the truth; and none, too, however wayward, haughty, and petulant that defence may sometimes have been, who will not heartily respond to the noble sentiment with which he closes:—"Verum Imperator noster, Deus, milites suos ex acie fugere non vult; sed aut vincere, aut strenue fortiterque pugnantes, mortem oppetere. Non enim ipsis pereuntibus veritatis gloria perit, sed vivit, sed vincit, sed illo piissimo cruore sancitur, atque consecratur." For myself I feel that I could freely forgive the errors of his life had they been far more serious than they were, when I find him consciously upheld by such high inspiration; and see that amidst all its pride and storm he cherished so sincere a love for the truth, and so stern a determination to defend it, against all odds, and at every hazard.

Some apology, we feel, is due for having dwelt so long upon the man, when it is, in strictness of speech, with his doctrine that we are here alone concerned. We trust that this may be found in the fact, that he is at once the least known, and the best worth knowing of all logical writers. To return, however, to his work,—the only edition of this with which I am acquainted is that printed at Paris in the year 1530, 4to, and it is from this accordingly that I uniformly quote. This edition has not the title given above, but simply the following,—"*Laurentii*

Vallæ Romani De Dialectica, libri iii." In this work, as we have said, Valla allows the express quantification of the predicate in theory, and to a certain, but very limited extent, adopts it in practice. Before, however, referring to the passages* which contain the evidence of this, it may be worth while to look for a moment at what he says of *Conversion*. This is very curious and acute; and though it does not explicitly bring out his doctrine of the predicate, will yet very well serve as introductory thereto. In his chapter, "*De Convertenda Enunciatione*," he says as follows:—

"Hic locus admonet ut aliqua de conversione dicamus: nam licet major atque amplior significatio prædicati fere sit quam subjecti, sicut ostendi; non tamen amplius ac latius *accipitur prædicatum* quam subjectum. Ideoque cum illo converti potest, ut 'omnis homo est animal,' non utique *totum genus* animal, sed *aliqua pars* hujus generis; nam Cicero speciem partem generis vocat; *ergo aliqua pars animalis est in omni homine*. Item 'quidam homo est animal,' scilicet est *quædam pars animalis;* ergo 'quædam pars animalis est quidam homo.' 'Omnis leo est rutilis,' 'quidam leo est rutilis;' hoc est, quod quisque leo, et quidam leo partem aliquam habet sive quandam rutili coloris, non ipsum omnino rutilum colorem; ergo *aliqua pars rutili coloris* est in singulis leonibus, et quædam in quodam. Idem intelligo de infinito quod de universali, cum universaliter accipitur. Idem quoque de particulari singularique, cum particulariter singulariterque significat: nec aliter, cum totaliter accipitur, ut 'homo est *species* animalis,' id est *quædam species* animalis; ergo '*quædam animalis species est homo*.' In negatione ratio e diverso est, quando adest signum universale; ut 'nullus homo est satyrus,' id est 'nullus homo non [?] est ullus satyrus;' ergo

* I may state at once that I do not profess to give *all* the references to this subject which may be found in Valla. I give only the passages which I marked in a former reading, undertaken without express reference to the doctrine of the predicate. The urgency of the press is too great to allow of my going through it carefully again with this end specially in view.

'nullus satyrus non [?] est ullus homo.' Quando non adest, ut 'homo non est satyrus,' id est, '*ullus homo*,' '*ullus satyrus*;' ergo, 'ullus satyrus non est ullus homo.' Quando per totalitatem loquimur, ut 'satyrus non est *species* hominis,' id est, '*ulla species* hominis,' ergo '*ulla species hominis non est satyrus.*' Quando adest signum particulare singulareve, ut 'nonnullus piscis,' vel 'hic piscis fœtum enititur,' scilicet est aliquis ex illis piscibus qui fœtum enituntur; ergo aliquis ex piscibus fœtum enitentibus est aliquis, vel est hic. Item, 'ille piscis' vel 'hic piscis non est fœtum enitens, sed ova pariens;' videlicet ex iis qui fœtum enituntur, ergo aliquis piscis ex iis qui fœtum enituntur, sed ova non pariunt, non est ille, vel non est hic piscis. 'Thales est *unus* ex septem sapientibus,' id est *aliquis* ex septem, ergo 'aliquis ex septem Thales.' 'Pythagoras non fuit e septem sapientibus,' id est *ullus* e septem, ergo 'ullus e septem non fuit Pythagoras.'"—*De Dialectica*, fol. 37.

Valla has here manifestly penetrated into the true nature of conversion. His doctrine, in effect, is, that by explicating the proposition, the conversion is, in any case, a simple turning of the sentence. Thus, for example, when we say, "all man is animal," what do we mean? Obviously, that all man is *some* animal, or *a species* of animal, or *a certain species* of animal; therefore, "a certain species of animal is all man." In other words, that though the predicate notion is in general, absolutely considered, of wider extent than the subject notion, yet that when considered relatively in a proposition, its extent is always restricted to that of the notion with which it is connected; so that by expressing this restriction, that is, by explicating the proposition, the subject and predicate are always convertible terms, and thus all conversion is necessarily *simple*. He accomplishes this, it will be seen, by explicitly quantifying the predicate; as, no man is a satyr—that is, *any satyr*. He has, however, blundered in the example. He should have given *ullus* for *nullus*, or *est* for *non est*.

We pass on, however, to his more explicit judgment in this matter. In the third book of his Treatise, Valla considers the right of the predicate to the marks of quantification in a brief chapter devoted expressly to this subject. It is headed, "*Dum signum applicatur prædicato, dumque abest a toto syllogismo signum,*" and is as follows:—"Hactenus locuti sumus cum signum universale applicatur *subjecto:* quid cum applicatur *prædicato?* Certe pari ratione; quæ exempla breviter subnectam, 'Tu amas *omnes* tuos cives, hi autem *omnes* sunt cives tui, ergo, tu amas hos *omnes.*' Hoc universaliter; particulariter vero si assumas, 'hic est civis tuus,' concludasque 'ergo, tu amas *hunc;*' sive diverso exemplo, 'Deus est ubique,' id est in *omni loco*, 'Tartarus est locus, ergo Deus est in Tartaro.' Hoc affirmative; negative sic, 'tu nullum civem tuum, sive nullos cives tuos amas, hi omnes sunt cives tui, ergo *neminem* vel *nullum* horum amas.' Item, 'in nullo loco scelerato est Deus, Tartarus talis est, ergo non est in eo Deus.' Exempla quæ attuli per signa universalia, si tollamus signa, *eandem vim* habebunt redacta ad infinita, ut superiore libro probavi; ut, Deus non est in loco scelerato, sive in locis sceleratis, *subauditur* enim *ullo*, sive *ullis;* tu non amas cives tuos, *subintelligitur omnes.* Idem fit in superioribus exemplis, ac cæteris omnibus."—Cap. xlvii. fol. 62.

Here the quantification of the predicate is explicitly allowed; and though the examples given of its lawfulness be incorrect, the rules of the common doctrine are falsified. For these examples are *affirmative* syllogisms of the *second* figure, contrary to the law that all valid reasonings in that figure must be *negative.* It is also further shown in this chapter that the quantity of the predicate is invariably a *determinate* one, and that when not so expressed, it is nevertheless always understood.

Valla here accordingly allows the quantification in theory, elsewhere he follows it in practice. Besides the examples given above, I remember two other passages in which he does this.

The first is, when speaking of *subcontraries*, he employs the

express quantification to prove that these cannot both be false. The passage is as follows :—

" Quocirca propria et pene sola subcontrarietas est in pronominibus ac propriis nominibus, nunquam (ut dixi) utraque parte vera. Quo magis illorum confutatur opinio, quibus placuit duas aliquando subcontrarias simul esse falsas, *ubi eorum prædicatis adest signum universale ;* ut ' Plato est *omne* animal,' ' Plato est *nullum* animal.' Neque enim sunt veræ subcontrariæ quarum secunda non negat quod prior affirmat. Habet itaque illa affirmativa, ' Plato est omne animal,' suam negativam, ' Plato non est omne animal;' et hæc negativa suam affirmativam, 'Plato est *aliquod* animal,' quia *ullum* dicere non possumus."—Cap. xxxv. fol. 48. The whole passage is longer, and the quantified predicate is used in illustration of the same point to the end of the chapter; but the above extract may suffice to illustrate this use.

The second passage is contained in a brief but important chapter, headed, " *Syllogismi per totum et partem.*" The two last sentences contain the specific examples, but the whole chapter is well worth quoting, and the more so, since in some of the earlier examples also the predicate is quantified. It is as follows :—

" Similis ratio in* toto et parte, quæ in genere et specie ; quæ

* Valla seems somewhat strangely to employ the terms *whole* and *part*, exclusively in relation to *physical wholes and parts*. In this chapter, accordingly, under the general head of whole and part, he confines his attention entirely to these, without making any reference to the wholes and parts which had been commonly discriminated as *logical* and *metaphysical*. To the *logical* or *extensive* whole, indeed, no express reference was necessary, since all ordinary syllogistic reasonings (his own amongst the rest) proceeded in this quantity, it being the only one formally recognised in the science. To the metaphysical whole he himself refers elsewhere. In a previous chapter, devoted to the consideration of the *order of the syllogistic parts*, he gives an example of a reasoning in the metaphysical or comprehensive whole, and very sagaciously asks, why the syllogism does not proceed in this order, from the individual or species to the genus—from the narrower to the wider notion? " What is the reason," says he, " that we may not construct a syllogism thus—' Socrates is man ; but all man is

exempla brevissime subjungam. Prima forma erit hæc, 'Tota Italia est in Europa; tota Campania est in Italia; ergo tota Campania est in Europa.' Altera quæ hujus particularis est, hæc erit, 'Tota Campania est in Italia; Neapolis est *pars* Campaniæ; ergo est in Italia.' Tertia, negativa, hæc, 'nihil Italiæ est in Asia; tota Campania est in Italia; ergo nihil Campaniæ est in Asia.' Quarta quæ hujus particularis est, hæc, 'Nihil Ægypti est in Africa; Alexandria est *aliquid* Ægypti; sive *pars* sive *pars quædam* Ægypti; ergo non est in Africa.' Nam 'nihil,' idem est quod 'non aliquid,' sive 'non quiddam,' id est non ulla res, sive non quædam res, quemadmodum superius docui; sicut 'omne' et 'omnia' substantivum, id est omnis vel omnes res.

"Quando *adest prædicato signum*, hæc quoque sint exempla; '*totum* corpus anima nutrit; toti ungues sunt *pars* corporis; ergo *totos* ungues anima nutrit.' Vel assumendo particulariter, quæ est secunda forma; 'hic unguis est *pars* corporis; ergo *hunc* unguem anima nutrit.'

"Item negative: 'Nihil corporis anima negligit; toti ungues sunt *aliquid*, vel *pars* corporis, sive hic unguis est *aliquid*, vel *pars quædam* corporis; ergo nihil unguium, aut non hunc unguem anima negligit."—Cap. xlix. fol. 62.

It will be seen that in these last examples the rules of the common doctrine are again falsified; for they contain syllogisms of the second figure, some of which are affirmative, and others particular. The examples may, indeed, be objected to.

Such is the doctrine of Laurentius Valla on the point in question; and it will be seen from the extracts we have given, that he recognises (though appreciating very partially and imperfectly its significance) the express quantification of the predicate.

animal, therefore Socrates is animal;' ascending as it were by certain steps, Socrates the individual, man the species, animal the genus?" This was in effect asking, though he himself probably did not see the full meaning of his own question, why the syllogism in logic did not proceed in the whole of *comprehension* as well as in that of *extension*; a wise question, which was not replied to, by subsequent logicians, and remains still unanswered.

The two next witnesses whose evidence I have to quote in favour of a quantified predicate, have this much in common—that they were contemporaries—were both men of great learning and ability—both acute writers on logic—both well and widely known in their own day, and that their names and works have long since passed into utter forgetfulness. It may, I believe, be added, that I am the first in modern times to have directed any attention to their writings;—they are Jodocus T. Isenach of Erfurt, and Ambrosius Leo of Venice. Of these we shall take the latter first, since, as a fellow-countryman, his evidence will naturally enough follow that of Laurentius Valla.

Ambrosius Leo* was a physician at Venice, and flourished

* Ambrosius Leo, called from Nola the place of his birth *Nolanus*, was one of that noble band of men, distinguished for varied genius and scholarship, whose labours towards the close of the fifteenth, and commencement of the sixteenth centuries, conferred on Venice a name of imperishable renown. He was, as stated in the text, for many years a physician in that city, but like several of his craft at that time, was not only skilled in medicine as a physician, but also profound as a philosopher, erudite as a scholar, and accomplished in all worthy and noble arts as a gentleman. His very name, however, seems to have been long since forgotten, and his works to have passed into complete oblivion. For a time, indeed, these seem to have been kept in some remembrance, since they appear in some of the older catalogues of distinguished works and authors. Thus, Simler, in his epitome of the Bibliotheca of Conrad Gesner, says, "*Ambrosius Leo* Nolanus scripsit opus quæstionum, tum aliis plerisque in rebus cognoscendis, tum maxime in philosophia et medicinæ scientia. Impressum Venetiis 1523. Idem edidit Castigationes in Averroem, qui liber magnus est, ac totius philosophiæ thesaurus. Sunt enim quasi commentarii quidam, ordine in singulos Aristotelis libros. Excusæ Venetiis 1517. Actuarii Johannis Zachariæ filii de urinis libros septem, ex Græcis Latinos fecit. Impressi Basileæ apud Cratandrum 1528."—(*Epitome Bibliothecæ Conradi Gesneri per Josiam Simlerum. Tiguri* 1555.)

And Vossius adds to this comment the following:—"Anno 1517, ac deinceps, non exiguæ eruditionis laudem reportavit Ambrosius Leo Nolanus, vir Latine Græceque doctissimus, philosophus idem, ac medicus insignis. Hic præter ea, quæ a Simlero memorantur, reliquit libros tres de Nola non incuriosè perscriptos: quorum sæpius meminit Leander Albertus in descriptione Italiæ: imprimis quo loco agit de Nola."—(*De Hist. Lat.* L. iii. c. xii.)

He appears to have soon lost even such distinction as this, for his name

during the latter part of the fifteenth and the beginning of the sixteenth century. He was the author of several smaller treatises, but his greatest production is a work against Averroes,

does not appear in any of the later catalogues of a similar kind which I have been able to examine. Indeed, for some time after having obtained his work against Averroes, I could not find out who or what he was. At length, however, I discovered that he was a friend of Erasmus, the latter having become known to Leo during his stay in Venice, and having afterwards corresponded with him. In the Epistles of Erasmus, accordingly, there are a few scattered references to Ambrosius Leo, and to this source I am mainly indebted for the few particulars of his history with which I am acquainted.

The first mention of Leo which we meet with in the Epistles, is in a letter written to Erasmus by John Watson, and dated from Cambridge in the month of August 1515. Speaking of a recent visit to Venice, Watson says, "I conversed almost daily with the physician Ambrosius Leo in the apothecary's shop at the sign of the Coral. I remembered him from what you had said of him, in connexion with the proverb, δὶς διὰ πασῶν. He did many things for me, for your sake." The reference here is to the "Adagia" of Erasmus, who, in his commentary on the proverb quoted above, refers to Ambrosius Leo in the following manner:—"Etenim cum hæc meis illinirem commentariis, forte fortuna supervenit Ambrosius. Leo Nolanus philosophus hujus tempestatis eximius, et in pervestigandis disciplinarum mysteriis incredibili quadam diligentia solertiaque præditus; neque vero mediocriter exercitatus evolvendis et excutiendis utriusque linguæ scriptoribus." —(*Adagia Erasmi*, in h. l.)

In the summer of the year 1518, Leo himself writes to Erasmus, and after referring to a small work which he had written on the history of his native town and district, Nola, and to other labours in which he had been engaged, tells him that he has completed a great work, divided into forty-six books, peripatetic in doctrine, and written against Averroes. Erasmus writes a long and very interesting letter in reply, almost a twelvemonth afterwards, in which he calls to remembrance the pleasant intercourse he had had with Leo and his brother scholars at Venice, and congratulates him upon the happy fortune which had cast his lot among the most learned scholars and in the first city of the world:—"Quo minus expectatæ venerunt tuæ literæ, *Ambrosi* doctissime, hoc mihi plus voluptatis attulerunt. Sic enim mihi totam illam nostræ consuetudinis memoriam renovarunt, ut eas legens apud *Venetos* mihi viderer agere, veteres amicos meos tueri coram et amplecti, *Aldum*, *Baptistam Egnatium*, *Hieronymum Aleandrum*, *M. Musurum*, te cum primis amicorum omnium suavissimum. Agnosco lepidissimos tuos mores in epistola tua, quæ tota jocis ac salibus scatet. O te felicem, cui contigerit in pulcherrimis studiis, et in urbe facile omnium magnificentissima, inter patricios et eruditos viros consenescere!"

entitled "*Ambrosii Nolani Castigationes, adversus Averroem.*" This was first published at Venice in the year 1517, and again at the same place in 1532. The first part of the work is occu-

He afterwards expresses his earnest wish that the book against Averroes were published.

We hear no more of Leo in the Epistles till the year 1528, in which year he seems to have died, for in the month of October in that year, Erasmus writing to a friend, says:—"*Ambrosium Nolanum* nobis ac studiis ereptum doleo, sed quandoquidem omnibus semel est moriendum, ille nec vixit incommode multos annos, nec infeliciter mortuus est."—(*Opera omnia Erasmi. Ed. Clerici.* Lugd. Vol. iii., pp. 161, 334, 506, 594.)

The most considerable of the works of Ambrosius Leo, both in value and extent, is evidently this one against Averroes. It is a large folio volume, containing upwards of 1100 pages; and comprises within itself, as Simler says, a perfect storehouse of philosophy. He follows Averroes pertinaciously into almost all subjects, and seems equally at home in logical, mathematical, physical, or metaphysical discussions. I speak, of course, only from a limited knowledge of the work, having only consulted it in relation to particular subjects in which I felt specially interested; but the acuteness and knowledge it displays seem equally balanced and both great. The reading of Leo, indeed, appears to have been not only very extensive, but critical and exact; he is critically read (as were all the learned men of his time) in ancient Greek philosophy; and what was a less common accomplishment, seems also quite familiar with all the later Greek and Latin commentators. The wide reading and varied sagacity which it displays, as well as the size of the work itself, are quite sufficient to explain the declaration he playfully makes in writing to Erasmus, that he did not waste away his nights in bed.

This volume is, as I have said, now of the greatest rarity. The biographers of Averroes, as far as I can find, are ignorant of its existence. The ordinary bibliographers make no reference to it. It is not, so far as I can ascertain, in any of the public libraries of the country. And what, perhaps, is a stronger proof of its rarity than anything else, and proves it to be as little known on the continent as in this country, is the fact, that a man so curiously and widely read as Morhof, should not only never have seen it, but expresses his belief that it was never published. In his *Polyhistor*, Morhof, while referring to the notices in the letters of Erasmus that such a work was in preparation, says, at the same time, that he does not believe that it was ever really published.

In abatement, however, of the statement, as to the utter oblivion into which the name of Ambrosius Leo has fallen, I should say that it is still remembered in connexion with his small work on the history of Nola, which is not very rare, and is still, I see, referred to in connexion with the history of the Italian states.

pied with a detailed criticism of the commentary of Averroes on the Organon; and in this he examines, among other statements, what Averroes says on the passage in the book touching enunciation relative to the quantification of the predicate. We have already given the passage from Averroes. Leo joins issue with him on this statement; he takes the case which is also taken by Averroes, but not referred to by Aristotle,—that in which the predicate is quantified particularly,—and he defends against Averroes the validity and usefulness of such quantification. The passage in which he does this is a somewhat long one; but as the rarity of the work is such as to preclude anything like general reference, it may be worth while to give it entire. It ought to be premised, however, that the text is in such a state, partly through carelessness in printing, partly through excessive and strange contraction, that the making it out, in many cases, is a kind of divination. It is as follows:—

"Aliud est non recipere *rem*, et aliud non recipere *divisionem rei;* ut aliud est non recipere esse genus, id quod dicimus pedestre, et aliud non recipere divisionem pedestris in bipes et multipes; unde Aristoteles genera facillime recipit, divisiones vero eorum facile non recipit. Non igitur, si enunciationes quæ in prædicato habent clausuram non dividuntur, etiam non recipiuntur, nam existere possunt etiam sine divisione; sed potius si non recipiuntur, non etiam dividuntur: quamobrem Aristoteles monet non esse recipiendas, non autem non esse dividendas. Idema ptius in primo Priorum docuit. 'Ut similiter,' inquit, 'eligendum, et quæ ipsum sequitur tota, per eandem causam; ipsum autem quod sequitur, non esse sumendum totum sequi. Dico autem, ut *in homine esse omne animal*, aut *in musica omnem disciplinam;* sed tamen simpliciter sequi, quemadmodum antea monuimus. Etenim inutile alterum et impossibile, ut *omnem hominem esse omne animal*, vel *omnem justitiam omne bonum;* sed cui alterum consequens est, in illo *omne* dicitur.' Hæc ille. Quare ab arte repelluntur tales propositiones ut ineptæ et malæ; non

autem non numerantur, vel dividuntur, propter eas causas: nam hac via qua ivit Averroes, non excludere moneremur, quas excludere velle ars ipsa comperitur. Quinetiam ubi legisset Averroes hæc Aristotelis verba: ‘ Sed universale prædicatum universaliter prædicare, non est verum; nulla enim affirmatio vera erit, in qua prædicatum fuerit universaliter universale, ut, *est omnis homo omne animal:*’ vidissetque *nihil dictum esset ab Aristotele de nota particularitatis,* quonam modo se haberet, si etiam prædicato termino addita fuisset. Voluit eum locum, veluti mancum, exponendo perficere; dicens de *omni clausura,* ut si universalis clausura est addita prædicato, enunciatio erit falsa, si particularis, erit superflua. Aristoteles vero, neque *hic,* neque in loco *Priorum* prædicto, meminit particularitatis, atque superfluitatem eam non particulari tribuit, sed universali. Quare *duobus modis* videtur Averroes aberrasse. Tu vero si melius fueris interpretatus, videbis clarius aberrasse Averroem, nam hoc in loco Aristoteles exacte dixit. Namque si ejusmodi universalis cum prædicato quod *universaliter* prædicatur, est falsa semper, nullamque talem esse arti aptam, tenendum est. Quare, si universalis ea ejecta est, etiam ea universalis cum prædicato quod *particulariter prædicatur* ejicienda est, vel si vera sit? Non enim opponi potest illi, quod in arte ipsa non habet locum; præsertim quum in hoc loco omnis enunciatio considerata in oppositione collocatur. Quinetiam neque usquequaque nota *particularitatis* addita prædicato superflua est, neque falsam reddit enunciationem. Dicentes enim, *omnis substantia quoddam ens est,* vere dicimus; atque si determinamus ita dicentes, non etiam superflua erit ea additio. Dicentes enim *substantiam esse ens,* verum dicimus, non quia ipsum ens, usquequaque inest prædicato substantiæ, sed quia *pars* entis est, quæ de substantia prædicatur. Quod, ubi determinantes, significamus, non inepte facimus et superflue; monemus enim ita, ne per multa vagetur audientis animus. Quamobrem in more est Aristoteli uti hujusmodi genere loquendi, *cum ea nota addita prædicato.* Veluti

in primo De Moribus, 'Omnis ars,' inquit, 'et omnis doctrina atque actio, similiter et electio, bonum *quoddam* expetere videtur;' et in sexto, 'Divinæ hæ omnes,' inquit, 'unum *quoddam*, genusque *quodpiam* exceptum sumentes, de hoc, non de ente simpliciter, neque ut est ens, considerationes suas efficiunt.' Quamobrem et si nota *particularitatis* addita prædicato faciat enunciationem ineptam in oppositionibus; non usquequaque tamen inutilis est, atque idcirco Aristoteles *de ea nihil locutus est.* Nam quoad oppositionem, de ea determinatum est—non esse recipiendam; quo vero ad modum loquendi determinate—non esse rejiciendam putavit, *sed non rejiciens illam admisit.* Quod si de nota *universalitatis* addita prædicato, qua *superflua* est, locutus est in Prioribus Analyticis, hic vero *non* locutus est, nihil mirum est; hic enim, de oppositionibus enunciationum disputaturus, considerat eas enunciationes, quæ in eis clausuram (?) ponunt, quæ vero inesse non potest in oppositione, illa rejecta manet, *nec oportet amplius considerare et de rejecta,* an sit in ea *superfluitas.* In priore vero Priorum prohibetur *nota universalitatis in prædicato*, tum quia est impossibilis propositio, tum quia si esset vera, esset inutilis illi, qui facultatem quærit medii inveniendi; quippe quod ei satis sit, simpliciter prædicatum referre.—His ita se habentibus, patet male dixisse Averroem de nota *particularitatis*, addita prædicato, tum quia non semper est superflua, tum quia superfluitas quæ spectabat ad universaliter prædicatum, transtulit ad particulariter prædicatum."—(*Castigationes*, &c., *in lib. De Interp.*, fol. 46.)

This is, on the whole, the most elaborate and acute criticism on this passage from Aristotle which I have met with; and it quite triumphantly establishes against Averroes the particular quantification of the predicate. The way, too, in which Aristotle himself is made to uphold this view is somewhat ingenious:—that since, on the one hand, he does not reject it in theory, and on the other actually adopts it in practice, he must be held to have received and approved of the particular quantification of the predicate. Leo is very careful, while rejecting the inter-

pretation of Averroes, not to oppose Aristotle; and I am half disposed to think that he was led into the adoption and defence of this particular quantification, as much through a determination to oppose Averroes when this was possible, without directly contradicting Aristotle, as from any previous insight into the question. His opposition has, however, in this case, led him into the partial adoption of a truth, which few of the commentators on Aristotle have at all perceived, but which he has so far very well stated and defended.

Jodocus Isenach,* or Justus Jodocus of Eisenach, was pro-

* Justus Jodocus Trutvetter Isenach, or as he was more commonly styled, Dr. Jodocus Isenach, was one of those devoted adherents to the ancient system of things, who formed so numerous a class in Germany at the beginning of the sixteenth century. Monastic scholars they were, for the most part, who were hostile to the Reformation, because they discerned in it a reaction against scholasticism, rather than because it menaced the unity of the Catholic Church. In the seats of learning, in Germany in particular, indeed, the battle of the Reformation was fought rather on the ground of letters than on that of religion; and when a religious plea was ostensibly urged in defence by those in authority, it was generally only as a mask under which they could more effectually attack their opponents. By these men the true faith was identified with an ignorance of letters and a knowledge of scholasticism. Those, therefore, who sought to disparage the latter, and to introduce the former, were necessarily heretics, and were persecuted as such. The fierceness of this persecution, indeed, combined with the obstinacy of those in power in clinging to a system now obsolete, determined a crisis in the struggle for improvement which had long been gradually going on, and hastened the complete reformation which soon followed. They would admit no innovation whatever in the existing system of instruction; they resolved not to modify in any particular their philosophical faith or teaching; and by thus blindly refusing to give up anything, lost all. To this class, as we have said, Isenach belonged; and to this it is probably to be attributed that so few particulars can now be gleaned of his history. Hardly any amount of individual genius was sufficient to save a single one of the vanquished in that warfare, from the oblivion into which all speedily fell. To those who were interested in the revival of letters, and the general progress of the Reformation, it became almost a duty to forget the names and reject the works of the abettors of ignorance and barbarism. Amidst the general enthusiasm which the new life had inspired, few were sufficiently interested in those who had sought to crush it at its birth, to redeem their names from forgetfulness, or hand down any record of whatever virtues they possessed, to posterity.

fessor of theology and philosophy at Erfurt during the latter part of the fifteenth and beginning of the sixteenth century; and if the slender accounts which I have been able to obtain of him be correct, was afterwards called to teach in the new uni-

Accordingly, with the exception of the very few particulars mentioned in the text, no specific biographical account of Isenach is to be obtained from any of the ordinary sources of information. The particulars there given are obtained from the Zedlerian Lexicon, which being one of the older encyclopædias, devotes six lines to his memory;—that being, I believe, the longest biography of Isenach to be found.

I have obtained, however, if not some additional particulars of his history, at least some materials for forming an estimate of his character, from another source, viz., the Letters of Luther, which contain some interesting references to him. Isenach may indeed be said to have been specially connected with the Reformation in Germany, since Luther himself was first his pupil, and afterwards, I was about to say, his murderer, but I ought rather to say, the cause of his death. Many grave accusations have been brought at different times against Luther, but none that I am aware of have ever laid this particular crime to his charge. He was notorious, indeed, for the summary manner in which he dealt with his opponents; but it was still not exactly in this literal sense that he was in the habit of destroying them. He was known to be a mighty man—mighty in the practical power which force of will and fiery enthusiasm bestow—mighty in the Scriptures—mighty, for that matter, in bodily strength; but it was, nevertheless, of the former kind of force rather than of the latter that he was used to avail himself in controversy; so that there would seem no just ground on which to urge such a serious charge. It is one, however, to which Luther himself in part pleads guilty. How far he really was so must be judged of from the sequel.

Luther was, as we have said, the pupil of Isenach. He was placed under his care, as it would appear, by his parents, in the year 1498, and continued for four years to attend his teaching at Erfurt. The two first of these were occupied with grammar, rhetoric, and other elementary studies. The third was devoted to logic; but he does not seem to have displayed any particular aptitude for the detail of that science, as he certainly does not afterwards recall the time thus spent with any particular satisfaction. After leaving Erfurt, Luther seems still to have kept up some communication, more or less direct, with Isenach. In particular, he seems to have been very urgent with him on the subject of scholasticism. Directly, by personal converse and by letter, and indirectly through his friends, Luther laboured earnestly and incessantly to modify his views as to the value of dialectic in theological training, and to abate his zeal in the interest of scholasticism. He was often, indeed, carried away by the strength of his feelings on these subjects; and what was intended as remonstrance became downright and stern denunciation. It was hardly to be supposed that Isenach

versity of Wittemberg. If this were the case, he must have been a distinguished man, since none but the best men of the time were called to occupy posts in that university. That he really was so is confirmed by the manner in which he is referred

would be prepared to listen calmly to these denunciations of his favourite studies. He regarded them indeed with the greatest grief and indignation,—feelings which deepened in proportion as Luther's zeal increased, and were aggravated by the reflection, that this contemptuous rejection of what he held most valuable proceeded from one of his own pupils. This was indeed that "most unkindest cut of all," that went far to sever the thread of his earthly life: so that Luther, on hearing of his death, writes to a friend that he fears he is responsible for having hastened that event,—so grievously had Isenach taken to heart his rash and profane condemnation of the sacred writings of the schools; in short, that he had died of his (Luther's) contempt of scholasticism:—"Hac hora," says Luther, writing to Spalatin, December 1519, "ex socero Lucæ [Cranach] pictoris audivi, excessisse e vivis D. Doctorem Isenacensem Erfordiæ. Timeo et me causam acceleratæ suæ mortis fuisse; tantum ægritudinis fuit animo ejus ex meis, ut dicitur, profanitatibus et temeritatibus, quibus scholasticam theologiam doluit incredibiliter contemni. Dominus misereatur animæ illi. Amen." —(*Luther's Briefe, Ed. De Wette*, vol. i. p. 373.)

How far this was likely to have been the case will be better seen from the following extracts, which I translate from Luther's letters, on account of their interest as illustrating the character of Luther, of the times, and of Isenach.

The first extract is from a letter written in February 1616, to John Lange, Prior of the Augustinians at Erfurt, inclosing a letter which he had written to Isenach against the existing course of study. It is as follows:—

"I send you this my letter to the excellent D. Jodocus Isenach, full of discussions against logic, philosophy, and theology,—that is to say, of blasphemies and maledictions against Aristotle, Porphyry, and the Sententiaries —the accursed studies, to wit, of the age. For so it will be interpreted by those who have vowed, not for five years, as the Pythagoreans, but constantly and to all eternity, to keep silent as the dead—to believe all things —to be obedient listeners—and never, even in joke, to venture a skirmish, or to breathe the slightest word against Aristotle and the Sentences. For what will not be believed as truths by those who have such faith in Aristotle—who, himself the most calumnious of all calumniators, attributes to others things so absurd, that an ass or a stone could not possibly hold their peace at them?

"See to it, therefore, that you carefully deliver these to that same excellent man, and be sure to smell out what judgment he or any of the others may give concerning me in this matter, and let me know. For I desire nothing more earnestly than to unmask that actor who has so befooled the

to by Luther, who speaks of him as "*princeps* dialecticorum nostra ætate." Isenach was the author of several works on various branches of philosophy; his logical treatises are, however, two, a larger and a smaller one. The former was en-

Church with his Greek guise, and to make his shame manifest to all, had I only leisure.

"But the greatest sorrow to me is, that I am compelled to see so many of our brother monks, endowed with excellent genius for all worthy studies, waste their lives and lose their labour amidst such filth as this; nor do the universities cease to condemn and burn good books, while at the same time they dictate, or rather dream out bad ones.

"I wish that Magister Usingen, and Isenach to boot, would abstain, in fact, contain themselves, for a while from these labours. My repositories are all filled [with writings] against their publications, which I am convinced are worse than useless; and all others would think as I do, were they not (as I have said) laid under an obligation of silence."—(Pp. 15, 16.)

The second extract is from a letter written in May 1518 to Spalatin, in which Luther gives him an account, after his return to Wittemberg, of the good reception which he met with from the Count Palatine at Heidelberg, and of his conferences with Isenach and Usingen. He says:—

"To the Erfurthians my theology is a dish of death in the pot—rewarmed; and Dr. Isenach made himself remarkable at Heidelberg, by prefixing to all my theses a black theta, [a mark of reprobation,] according also his written testimonial, that he considered me an ignoramus in logic, not to say divinity.

"I would have disputed likewise among them, [those of Erfurt, to wit, on his return from Heidelberg,] had not the Litany days* prevented. I had, however, a private conference with Doctor Isenach; and if I did nothing more, made him understand that he was unable to prove his own positions or to confute mine; nay, that their opinions, [or perhaps sentences, in which case the word will refer to those of Lombard,] were that beast which is said to devour itself. But the fable falls on deaf ears: they obstinately stick to their distinctions, confessing, howbeit, that these are established upon no authority, except what they call the dictate of natural reason, which in our eyes, who preach no other light than Christ Jesus—the true and only illumination—appears simply as a night of chaos.

"With Dr. Usingen I strove more than with any other (for he was my companion in the carriage) to persuade him of the truth. But I know not whether I made any way; I left him in thought and wonderment: so strong is prejudice when we have grown old in evil doctrines. But the minds of all the young were diametrically opposed to these veterans; and

* In the old universities there were certain holidays on which the prelections were put a stop to, and certain others on which not only the prelections, but also the academical disputations were intermitted. The days on which the Litany was used marked the latter.

titled, "*Summa Totius Logicæ*," and was printed at Erfurt in the year 1501. The latter, which seems to be an abridgment of the previous work, is entitled, "*Epitome seu Breviarium Dialecticæ.*" It is without any date, but was probably published not more

my hope is good, that as Christ passed to the Gentiles when rejected of the Jews, so now His true theology which these opinionative seniors repudiate, may be embraced by the young."—(Pp. 111, 112.)

The third extract is from another letter, written in the following month of the same year, to Spalatin, touching the value of dialectic in theological studies:—

"You ask, how far I think dialectic is useful to theology; verily I do not see how it can be other than poison to a true divine. Grant that it may perhaps be useful as a sport or exercise for youthful minds, still in sacred letters, where simple faith and Divine illumination are to be awaited, the whole matter of the syllogism is to be left below, even as Abraham, when about to sacrifice, left the youths with the asses. And this, John Reuchlin, in the second book of his Cabbala, sufficiently confirms. For if any dialectic be necessary, that given by nature is enough, by which a man is led to compare one belief with another, and so to arrive at the truth. I have not unfrequently engaged in discussions with my friends as to the profit to be gained from this so sedulous study of philosophy and dialectic, and truly with one consent we have marvelled at, yea, bewailed over, the calamity of minds, finding in these studies no help, but rather a whole flood of hinderance.

"Finally, I have written to Doctor Isenach, the prince of dialecticians (as it seems) in this age, insisting most strongly on the same thing, which indeed cannot be denied, to wit, that dialectic cannot help theology, but rather hinders it, because the same grammatical terms are used in a widely different sense in theology and in logic. How, therefore, I say, can dialectic be of any use, when, after I enter on theology, the same term which in logic signified such a thing, I am compelled to reject, and to receive in another sense? And that I may not multiply words, take, for example, the following:—*Body*, in the tree of Porphyry, signifies a thing made up of *matter* and *form;* but such body cannot belong to man, seeing that in the Scriptures our body signifies *matter* only, not also *form*,—as where it is said, 'Fear not them which kill the body, but are not able to kill the soul.' Farther, I instance the absurd statement, that an angel is neither rational nor irrational; as also, that it is of no use to the Scriptures for a man to be called sensitive, rational, corporeal, animated; and briefly, the whole of that arrangement of the tree of Porphyry, I have said, and still say, is more trivial than an old woman's fancy or a sick man's dream, and justly, therefore, is it called Porphyrean, (that is bloody,) from the Christian souls, to wit, which it has slain.

"The good man took it much to heart, and affirmed that my sophisms

than a year or two after the former, since its press-work manifestly identifies it with the earliest productions of the sixteenth

could not be credited even by myself. But these worthies are the bondmen of Aristotle and Porphyry, and consider not *what* is said, but simply *who* says it. Hence it comes that they are not able to understand a single chapter of Scripture, much less to render it.

"If, therefore, you accept my judgment, dialectic, of whatever use it be in other things, in sacred letters only does harm. I myself have observed the doctrines and rules of the scholastic theology, and have designedly endeavoured to treat the inspired writings and those of the Fathers of the Church according to them; but (may God condemn me if I lie) I recoiled in horror from the confusion, worse than that of Tartarus, [which this treatment caused.] But I will make the same attempt on you when we meet, and shall then detail, what you now briefly hear."—(Pp. 127, 128.)

These extracts are very characteristic of Luther—of his honesty—his thorough out-spokenness—his utter want of sympathy with the ancient barbarism, and his fiery zeal for its destruction. When we remember, however, that such deliverances as these were addressed to a man of whose character and history the only remaining record is, that he was a "lover of the scholastic theology;" and remember also, that they came with the bitter aggravation of having been given by one who had enjoyed the best opportunities of knowing the worth of the things he despised, since he had heard their value expounded by the ablest lips—the case certainly assumes a very grave aspect; and one can hardly wonder that Luther should have felt some misgivings as to his innocence in the matter. On the somewhat extravagant hypothesis, that such a catastrophe was possible to the abettors of scholasticism, there is here amply enough to explain a broken heart; and certainly the mildest jury that ever was empannelled could not have acquitted Luther of manslaughter.

The works of Isenach are now altogether forgotten. This smaller one on logic is the only one that I have ever seen. My copy is quite perfect, but contains no date, printer's name, or place of printing, nor has it catchwords or paging of any kind. Its title is curious, and (except the punctuation) is as follows:—

"Epitome seu Breviarium Dialecticæ, hoc est, disputatricis scientiæ. Iterum jam recusum; planiori siquidem, et præceptorum, et exemplorum filo.

"Per D[octorem] Judocum Issennachenum.

"Illitium Empturienti.

"Non sum, O Lector, Breviarium Romanum Moguntinum, aut id genus aliud, quo sacri Deo flamines supplicia fundunt; sed Logicæ, quo pueri prima ejus rudimenta haurire poterunt. Eme modo; non dices olim, quod Calcearius Romanus de Corvo suo,—Opera, et impensa periit."

Then follow a dozen of verses by Daripinus, Poet and Orator Laureate, which occupy the rest of the title-page.

century. This is the only work of Isenach's with which I am acquainted; but the general knowledge and acuteness which it displays, certainly go far to vindicate the justice of the title which Luther bestows upon him; and to prove that he was not only an accomplished logician, but what is far more rare, an independent thinker in the science. It proves clearly, among other things, that he was familiar with the use of a quantified predicate; but what precise value he attached to it, or how far he really employed it in the science, it is extremely difficult from the work to determine. This difficulty arises mainly from the circumstance, that this treatise being simply designed as an introductory one, the longer, more novel, and abstruse discussions are left out of it, and we are referred for them to the larger work. This is the case with those which relate to the quantification of the predicate. When we come fairly upon the subject, and hope to have it fully discussed, we are disappointed in this, and get instead a quiet reference to the *opus majus*, which to those who only possess the *opus minus*, and have no access to the other, is provoking enough. Quite sufficient, however, remains in this smaller work* to establish the fact,

* This work, though relatively less, is not absolutely small. It is a quarto volume of some thickness, printed very closely, in the most contracted style of the most contracting era of black-letter printing. In this respect it is sometimes worse even than the work of Leo, three letters being often deemed amply sufficient for a word of three syllables, and sometimes for one of four. The text is, indeed, a perfect forest of large black-letter contractions, overrun with a tangled underwood of smaller black-letter contractions in the shape of notes, and intersected continually with tables designed to render clearer, and sometimes to supersede the divisions of the text, but which, owing to the ingenious interpenetration and general confusion of their bracketting, are in themselves a new and independent source of perplexity and bewilderment. This being the case, I will not undertake to say that I am familiar in detail with every part of the work. I have looked through the whole, read some parts carefully, and marked the passages which seemed specially to bear upon the subject in hand. It is more than probable, however, that some point of interest may have found its way into some of those labyrinths of note or table which I have not yet perfectly explored. The extracts here given illustrate clearly enough, however, the

that he was familiar with the quantification of the predicate, and that he employs it to some extent in the science. I shall accordingly extract from various parts of his work some of the passages which go to show this. These passages will necessarily be given out of their own connexion; and as I shall often be obliged to forego the comment they tempt, in order that this note may not be unduly extended, they will often be found to have no other relation to each other than their common reference to the principle in question. I shall first give some extracts from Isenach's exposition of *terms* and their *signs*, then from what he says of *propositions* and their *relations*, and finally select one or two passages from his comments on the *special rules of syllogism*.

In relation to *terms* he adopts the common division of *Categorematic*, and *Syncategorematic*,—the former including the subject and predicate of a proposition—the latter the various affections or modifications of these. On this second division he has the following passage, which I quote, both on account of its own precision, and for the sake of what is to follow:—

"Sincathegorema, quod per se et solitarie non est significativum alicujus rei vere vel imaginarie, sed junctum termino significativo et cathegorematico variat modum concipiendo rem significatam per ipsum, quod denotat ipsum accipi pro suo significato vel significatis aliquo more; puta universaliter, particulariter, singulariter, et cum iis; ut omnis, aliquis, iste, non. Nam dicendo *omnis*, nullam rem concipio vel intelligo; sed dicendo *omnis homo*, concipio vel intelligo hominem non simpliciter, sed universaliter *omnem*. Ita quoque dicendo *iste*, nihil addendo vel subintelligendo, nullam rem intelligo; sed quum dicitur *iste homo*, intelligo singulariter *hunc hominem* demonstra-

point in question, and are sufficient for the present purpose. I have some hope of being able to obtain the larger work of Isenach; and should it prove of sufficient interest, will hereafter give a fuller account of his doctrine.

tum. Idcirco dicuntur hujusmodi signa nihil significare sed duntaxat *con*significare. Unde nec grammatice, se solis possunt reddere suppositum verbo; nec logice, esse extrema propositionis, sed solum *determinationes* et *modificationes eorundem*. Et quia hujusmodi signa, ratione considerationis et habitudinis, (puta, universalitationis, particularisationis, singularisationis, distributionis, confusionis, et cum iis,) quam important circa terminos sibi additos, mutant sensa propositionis et sæpius veritatem vel falsitatem, idcirco logicus perquirit de ipsis hujusmodi passiones."

This passage will serve to show his just appreciation of the value of modifying marks as affixed to terms in restricting or extending, or in general in rendering definite their meaning. A little further on he says very significantly in relation to these :—

" Illud vero quod ad copulam principalem est suppositum, quocunque loco ponatur, est subjectum propositionis cum omni quod ipsum determinat, dempto sincathegoremate, sumpto irrestricte sive non restricte; ut ' caput canis pilis intextum habet homo decrepitæ ætatis:' ubi verbum '*habet*' pro suo formali significato est copula, et idem pro suo materiali significato cum hoc toto, '*caput canis pilis intextum*,' quod ipsum determinat, est prædicatum; subjectum vero est hoc totum, '*homo decrepitæ ætatis*.' Simili modo judicandum est de illis : ' homo omni animali principatur;' ' degeneres animos timor arguit;' ' velocibus alis mors volat;' ' ignis et aer sunt elementa calida.' Additur, dempto sincathegoremate sumpto irrestricte, *quum illud usu communi logicorum non est pars subjecti vel prædicati*. Sincathegorema autem sumi restrictive vel non restrictive stat in arbitrio utentis. Fateor tamen, quod usu communi logicorum tunc sumitur restrictive quum ponitur a parte prædicati; (ut ' Adam fuit *omnis homo*,') vel inter partes subjecti diversorum casuum, et determinat obliquum (ut ' conservans *omnem creaturam* est Deus.') Irrestrictive vero sive non restrictive frequenter sumitur quum

ponitur in principio propositionis secundum veram constructionem; ut 'omnis lapis est durus;' 'caput habet omnis homo;' 'verba dat omnis amans.'

"Scias tamen, quod sensus orationis variatur quum sumitur restricte et irrestricte, verbi gratia, 'omnis homo est animal:'—

"Sumendo signum 'omnis.'

Restrictive valet; 'aliquod existens, omnis homo est animal;' sic est falsa, quia nihil est dabile quod sit omnis homo.

Irrestricte valet; 'quicquid est homo est animal:' vel sic, 'de quocunque verum est dicere quod sit homo, de eodem verum est dicere quod sit animal;' sic est vera."

I give a single extract from a long chapter on *signs*, (in which Isenach often employs propositions with their predicates quantified,) mainly to illustrate his use of the terms *determinate* and *confused*. At first, from his casual use of these terms in other places, I thought that by the former he meant a term with a mark of quantity, and by the latter one without such mark; but it appears from his exposition and illustration that he simply means by *confused* a universal subject, and by *determinate* a particular or individual subject. The following is the passage:—

"*Confuse:* ita quod alterum extremorum denotatur ipsi convenire pro aliquo omnium suorum significatorum, hoc vel illo, et nullo certo vel determinato; ut 'omnis homo habet caput,' ubi denotatur quemlibet hominem habere caput, nec omnes aut plures, unum, sed quemque suum. Et hic dicitur supponere communiter, confuse, tamen disjunctim sive non collective.

"*Determinate:* ita quod alterum extremorum denotatur ipsi convenire, inter omnia sua significata, pro aliquo certo et determinato, vel aliquibus certis et determinatis; ut, '*caput habet omnis homo*;' ubi denotatur esse aliquid certum et determinatum

caput quod quilibet homo habeat. Hic dicitur supponere determinate." To illustrate this by an example which is given a little below:—" 'Omnis homo non est omne animal,' ubi animal supponit confuse tantum: 'Anna non est omnis mulier,' ubi *mulier* supponit determinate."

We pass to the consideration of *propositions*. Isenach's view of the logical relation of a proposition is singularly just; and his exposition of its scientific capabilities and significance is at once comprehensive and exact. He explains in detail, that the matter of a proposition is its terms, and that its true logical significance ever lies in the affections of these, and the manner in which they are connected with each other. He divides the affections of propositions into those which belong to them considered in themselves, and those which arise out of their relation to each other. The former are of course *quality* and *quantity*. It is with the last member of this division alone that we are now concerned. In relation to it Isenach first gives the common doctrine, with its four-fold division founded exclusively on the quantity of the subject. He endeavours to explain the principle of his one-sided division, by saying, that the subject was selected as being the more important part of the matter of a proposition:—" Quantitas propositionis, hoc modo sumpta, penes subjectum principale, vel partem principaliorem subjecti, dicitur quantitas propositionalis; et ab ea propositio simpliciter denominatur aliqua denominatione ex jam dictis. Vocatur autem hoc nomine propter hoc, quia subjectum est prima et principalis pars materialis propositionis, atque principale fundamentum prædicationis, de quo cetera enunciantur."

He then gives a statement of his own, as a supplement to the common doctrine, founded on a far wider and juster consideration of terminal quantity. He asserts in effect, that the affection of quantity belongs to the *whole* matter of a proposition, and not to *one of its parts alone*, as hitherto exclusively considered; and that whether it fall on the subject or the predi-

cate it is equally of logical account. His statement is as follows:—

"*De quantitate terminali:* Solet etiam nonnunquam sumi quantitas propositionis penes quamquam partem materialem propositionis, (*i.e.*, *quemlibet terminum cathegorematicum,*) non curando quocunque loco ponatur. In hunc modum:—

"Omnis propositio in qua ponitur (quocunque etiam loco) terminus cathegorematicus

1. *Singularis*, est universalis: ut 'ille asinus istius hominis est tardigradus.'
2. *Communis*
   - *Distributus*, est universalis: ut 'oculus cujusque hominis est aqueus;' 'iste Deus est *omnis* Deus.'
   - *Acceptus determinate*, proprie est particularis: ut, 'hominis alter oculus est dexter.'
   - *Acceptus confuse* tantum, vel determinate reductive, est indefinita: ut 'Petrus est musicus.'"

He then goes on to make the following somewhat curious statement:—

"Hoc modo una propositio potest esse universalis, particularis, indefinita, et singularis; ut patet de illa: 'alter oculus est cujusque hominis (vel istius hominis) dexter oculus.' Hæc quantitas vocatur terminalis, et ab ea non denominatur propositio quanta *simpliciter*, sed cum addito; ut dicta propcsitio non denominatur simpliciter *universalis*, sed ratione illius termini hominis; nec denominatur simpliciter *particularis*, sed ratione illius terminus oculus; simpliciter vero denominatur *indefinita*, quia subjectum accipitur determinate reductive."

This he proceeds to apply to modal propositions, whose peculiarity, indeed, is logically considered, in the last resort, but an affection of the predicate.

The affections which belong to propositions considered in

their relation to each other are three—*opposition*, *equipollence*, and *conversion*. We shall extract without comment one or two sentences from what is said touching the first and last of these, and then pass on to the Syllogism. The following passages are from his discussions—the one of subalternate, the other of subcontrary opposition:—

"Terminus qui in subalternante stat confuse tantum respectu termini distributi in subalternata, non stet determinate respectu ejusdem termini distributi, sed accipiatur confuse tantum.... 'Omni tempore risibile est *omnis* homo;' 'aliquo tempore risibile est *omnis* homo.' Sed subalterna prioris est; 'aliquo tempore a risibile est omnis homo,' posito quod ly *a* faciat terminum risibile stare confuse tantum; vel illa, 'aliquo tempore omnis homo est risibilis;' vel ista, 'aliquo tempore risibile est homo.'...

"Si in una subcontrariarum ponitur aliqua universalitas, in altera omnia debent particularisari. Quare hoc non sunt subcontrariæ; 'aliquo tempore risibile est omnis homo;' 'aliquo tempore nullum risibile est omnis homo;' sed subcontraria prioris est, 'aliquo tempore risibile non est omnis homo.'"

The last sentence on this subject is the following, which is at once significant and disappointing:—

"Oppositio non solum sumenda est penes quantitatem propositionalem, sumptam penes subjectum propositionis seu principaliorem ejus partem; *sed penes quantitatem terminalem, quæ attenditur penes quamque partem materialem propositionis.* Potest itaque sumi oppositio, ex parte subjectorum, *prædicatorum*, et determinationum tam subjecti quam prædicati, atque etiam copularum. *Hoc est quod aliter dicitur.*"

The following is from his exposition of conversion:—

"Quod secunda, sive convertens, sequatur ad conversam, in bona consequentia, sic quod conversa non possit esse vera sine convertente: et propter hoc nihil debet universalisari in convertente quod non fuit universalisatum in conversa; nec terminus stans in conversa confuse tantum respectu termini distributi debet in

convertente stare determinate respectu ejusdem termini distributi, sed stet confuse tantum; vel terminus distributus in conversa non distribuatur in convertente. Cujus ratio est, quia in omni consequentia bona oportet caveri, ne arguatur a non distributo ad distributum, vel a termino stante confuse tantum ad eundem stantem determinate respectu ejusdem termini distributi.

"Propter defectum

Primi, non valet hæc conversio:

1. Omnis homo est animal; ergo, omne animal est homo; sed sic convertatur; quoddam animal est homo.
2. Nullus homo est *omne* animal; ergo, nullum animal est homo; sed sic convertatur; quoddam animal non est *omnis* homo.
3. Aliquod animal non est homo; ergo, homo non est animal; sed sic convertatur; quidam homo animal non est.

Secundi, non valet hæc conversio:

1. Cujuslibet hominis oculus est dexter; ergo, dexter oculus est oculus cujuslibet hominis; sed sic convertatur; ergo, dexter oculus est oculus alicujus hominis; vel sic, dexter oculus est cujuslibet hominis oculus.
2. Omni tempore risibile est *omnis* homo; ergo, homo est risibile omni tempore; sed sic convertatur; ergo, homo est omni tempore risibile, vel sic; ergo, homo est risibilis aliquo tempore.

" Volens itaque convertere aliquam propositionem, consideret diligenter, quæ sint ejus extrema, (puta subjectum et prædicatum,) atque habitudines logicas eorundem, (puta, suppositionem in genere, ampliationem, restrictionem, &c.,) *quas circa extrema exprimat, et subinde extrema transponat;* sic quod de subjecto fiat prædicatum ; et e diverso, constituendo aliam propositionem ejusdem qualitatis, in qua nihil universalisatur quod est particularisatum in priore, nec terminus aliquis stat determinate, respectu termini distributi, qui in priore, respectu ejusdem termini distributi, stabat confuse tantum. *Hæc enim conversio semper valet.*"

I quote the following passage mainly to show that Isenach saw clearly, what indeed he elsewhere more fully explains, that exclusive propositions distribute the predicate. It is the last passage in a chapter on exponibles :—

" ' *Tantum* homo est animal ' sic probatur: hoc prædicatum ' animal ' enunciatur de hoc subjecto ' homo,' et de *nullo alio ab eo*, (sive negatur ab omni alio,) et ita denotat per hoc signum *tantum.*—' Omnis homo est animal ' sic probatur : hoc prædicatum ' animal' universaliter verificatur de hoc subjecto ' homo,' (sive convenit subjecto pro omni supposito,) et ita denotatur per hoc signum *omnis;* ergo, &c. *De quo alibi latius diximus. Hæc pro rudimentis puerorum sufficiant.*"

It will be seen that both in this passage, and in the closing one treating of opposition, reference is disappointingly made for fuller discussion of the matter to the other work.

Isenach's discussion of the syllogism is, in every respect, the most important part of his book. He gives an acute preliminary exposition touching the general rules of inference, some of which, as partially relevant to the question in hand, I had designed to quote. His discussion of figure, too, is curious and interesting, especially his doctrine in relation to the fourth. These points of interest must, however, give way to those which more immediately refer to the question of the predicate. These

are the exceptions which he takes to the universal validity or necessity of the special rules of syllogism. He partially falsifies these by quantifying the predicate, as will be seen from the following passages:—

" 1. Ex puris affirmativis nihil sequitur formaliter in secunda figura.

" Cujus ratio est; quia contingeret medium in neutra premissarum distribui aut singularisari. Nam prædicatum non distribuit in affirmativis (saltem de *communi forma* propositionum, in quibus *non ponuntur signa pregnantia.*) Si vero hoc caveretur, valeret argumentatio; ut, ' omnis homo est *omne* animal;' ' omne risibile est animal;' ergo, ' omne risibile est homo.'

" 2. Secunda figura regulariter solum concludit negative.

" Nam, cum una premissarum debet regulariter esse negativa, oportet conclusionem esse negativam. Additur notanter, *regulariter*, quia, casu quo contingit *ambas premissas esse affirmativas*, sequitur etiam conclusio affirmativa ; *ut patet in priori exemplo.*

" 3. Minore existente negativa nihil sequitur formaliter, in prima et tertia figuris, directe concludendo.

" Quia contingeret argui a non distributo ad distributum. Nam, minore negativa, oportet majorem esse affirmativam, (quia ex puris negativis nihil sequitur,) et altera præmissarum negativa, oportet conclusionem esse negativam, et sic major extremitas, prædicatum majoris et conclusionis de communi forma propositionum, non distribueretur in majore sed in conclusione. Sed si hoc evitatur, (puta indirecte concludendo, vel quolibet aliter,) valet argumentatio; ut, ' omnis asinus est animal;' et

'nullus homo est asinus;' ergo, 'aliquod animal non est homo,' vel sic, 'nullus homo est *omne* animal.'

"4. Tertia figura regulariter solum concludit particulariter.

"Nam aliter contingeret argui a non distributo ad distributum ex parte minoris extremitatis. Hæc enim distribueretur in conclusione universali in qua subjicitur, et non in minore affirmativa in qua prædicatur: ut est cernere exemplo, 'omnis homo est animal; et, omnis homo est substantia; ergo, omnis substantia est animal.' Verum si illud cavetur, quomodocunque firma est argumentatio, ut hic: 'omnis lucidissimus planeta lucet; omnis lucidissimus planeta est *omnis* sol; ergo, omnis sol lucet.'

"5. Majore particulari, nihil sequitur formaliter et syllogistice, in prima et secunda figuris, directe concludendo.

"Cujus ratio est, quantum ad primam figuram, quia contingeret medium in neutra præmissarum distribui vel singularisari. Nam quum major sit particularis, medium quod in ea subjicitur, non distribuitur; et quum minor non posset esse negativa (ex superiori regula) in qua medium prædicatur, nec in illa distribuitur, de communi forma propositionum, uti hoc claret exemplo. 'Animal est asinus; et, omnis homo est animal; ergo, omnis homo est asinus.'" (Omitting his application of his rule to the second, I pass on to his refutation of it in relation to the first figure:) "Verum si hujusmodi *inconvenientia vitantur* (ut puta indirecte concludendo, vel quolibet aliter,) *valebunt argumentationes;* ut, 'lucidissimus planeta lucet; et, omnis sol est *omnis* lucidissimus planeta; ergo, sol lucet:' 'Animal currit; et omnis homo est *idem* animal; ergo, homo currit.'"

It is here clearly stated, that if the syllogism be taken in its regular form, as commonly considered, and as exclusively allowed by logicians, the rules are valid. The reason of this is

explained by showing what logical vice would be committed if they were violated; but it is quite truly added, that if we can avoid committing this vice in any other way than by obeying the rules, the syllogism is good, and the rules, therefore, no longer hold. This Isenach shows can be done by quantifying the predicate. He accordingly falsifies the two first rules by a syllogism of the following form :—

All A is all B.
All C is B. Therefore,
All C is A.

He partially falsifies the third rule by a syllogism in the following form, in which the predicate is not quantified in the premises, but in the conclusion :—

All B is A.
No C is B. Therefore,
Some A is not C. Or,
Not any C is all A.

The fourth rule is falsified by a syllogism in the following form :—

All B is A.
All B is all C. Therefore,
All C is A.

And finally, the last rule is falsified to its first division by one in the following form, which, except that it is less definite in quantity, is much the same as the preceding one :—

B is A.
All C is all B. Therefore,
C is A.

Such is a brief outline of the doctrine of Isenach in relation to the quantification of the predicate. It is clear, even from this imperfect account, that he was familiar with its use, and, to some extent, appreciated its value. I am disposed, however, to think that he was far more familiar with its somewhat indiscriminate use in practice than conversant with its true scientific

significance in principle. His insight into this does not appear to be great. Hence he often uses it capriciously, and without any particular end in view; and though, without doubt, he does occasionally employ it to simplify the working of the science, yet, after all, he does this very sparingly, and by no means to the extent we should expect from one apparently so familiar with its use. It is of course, however, as we have said, somewhat difficult to determine, upon such partial evidence, what precise value he did attach to the principle, since we are referred for this to discussions to which we have at present no access.

The last two writers whose names we have to quote in support of a quantified predicate are both much later than the preceding ones. We shall briefly quote from these the passages in which they partially allow in theory, or adopt in practice, such quantification.

The first is an Englishman, Joshua Oldfield, who, in his curiously discursive and ingenious "Essay towards the Improvement of Reason," which was published in London in the year 1707, touches, among other subjects, upon logic. Without professing to give anything in the shape of a regular system, he has some acute remarks on the syllogism, and among them the following, relative to the point in question:—

"The predicate of each enunciation is also supposed to be *universally* taken if denied, and *particularly*, when affirmed; so that in this latter case it ought to have a *note of universality added, if it be universally designed*, as it *may* be, in imagining a property, and *must* be, in giving a just definition, or a right description; for these ought to be made universal when the proposition is converted, and such predicate put in the place of the subject.

"Now, when the affirmed predicate is thus universally taken, the argument will certainly admit of being otherwise formed than according to the usual allowed *moods* or *modes*."—(P. 248.)

"Now, whereas it is commonly said, the enunciations must be

so and so, (as in the technical words before mentioned,) and that there can be no more concluding moods in such respective figures, it must be understood to be so upon the forementioned suppositions as to the *quantity of the predicate;* for otherwise, where this is universally affirmed, there may be, *e. g.*, such a mode as ITALI in the first figure; thus :—

I- Aliquod trilaterum est æquiangulum;
TA- Omne triangulum est (omne) trilaterum;
LI. Ergo, aliquod triangulum est æquiangulum.

In English, thus,—

I- Some three-sided figure has equal angles;
TA- Every triangle is any three-sided figure;
LI. Therefore, some triangle has equal angles."—(P. 250.)

These are the passages relative to the point in question which are to be found in Oldfield, who is the only English writer, so far as I know, by whom the quantification of the predicate is in any form allowed. It will be seen, however, from these extracts, how little he understood the principle which for the time he uses, since he even attributes to it none but a *material* cogency, and grants that the syllogisms commonly recognised by logicians are the only ones which are of formal, and thus of universal validity. It is also further manifest how limited was his view of its practical application; since, both in its statement and illustration, he confines his attention exclusively to the case of universal quantification, and this is considered only in relation to affirmative propositions which contain a definition or description.

The last instance to be adduced of the partial use of a quantified predicate is that of Godfrey Ploucquet. He lived during the greater part of the last century, was for many years Professor in the University of Tübingen, and published many small, but acute, and often original, treatises in connexion with logic and philosophy. The only work of his, however, with which I am acquainted is that entitled "Fundamenta Philosophiæ Specula-

tivæ," and published at Tübingen in the year 1759. In this work he employs the quantification of the predicate, in his treatment of propositions, to simplify their conversion. The following are the passages in which he does this, and they fully explain its use in his hands. I quote first, however, in order to render what follows intelligible, his own explanation of the peculiar symbols he employs :—

§ 34. "O præfixum denotat omnitudinem positive sumtam.
N præfixum denotat omnitudinem negative sumtam.
Q vel q. præfixa denotant particularitatem.

Duæ pluresve litteræ conjunctæ significant subjectum cum suis prædicatis. v. g. AB significat subjectum A cum prædicato B.

ABC significat subjectum A, cui inest prædicatum B, quod prædicatum B includit simul prædicatum C.

A—B denotat, A est B.

A > B denotat, A non est B.

N.A—B denotat, Nullum A est B.

A præfixum propositioni significat affirmationem universaliter sumtam.

I, affirmationem particulariter sumtam.

E, negationem universaliter sumtam.

O, negationem particulariter sumtam.

Cum seriei cuidam subjungitur signum, &c., denotatur series infinita, vel integra. Cum non subjungitur, denotatur series abrupta."

§ 36. "Sit primo, propositio universaliter affirmans, O.A—B. Hæc in generalibus et in symbolis spectata non infert hanc O.A est O.B sed O.A est q.B, § 24. Ubi vero notandum, quod particularitas nunquam intelligatur exclusiva."

§ 40. "Sit particulariter negans q.A > B.
Omne, quod est B, diversum est a quodam A. Ergo N.B est q.A.
Not. Operatio hæc vocari solet Conversio propositionum."

§ 41. "Apparet hinc, conversionem propositionum nihil aliud esse, quam transpositionem eorundem terminorum logice expressorum, nec quidquam in sensu ipso immutari. Si enim in sensu aliquid immutaretur, propositio non amplius esset hæc propositio. Ita nec ex particulari fit universale, nec ex universali fit particulare."

§ 43. "Sit propositio identica O.A—O.B: Hic A cum B identificatur, adeoque conversio fit O.B—O.A.

"Sint enim duæ series:

AB. AB. AB. &c.
CB. CB. CB. &c.

"Hic C non potest esse diversum ab A. Si enim B est idem cum A, tum B non potest inesse $\tau\tilde{\varphi}$ A & $\tau\tilde{\varphi}$ non - A, quia idem est idem.

"Cum usitatus loquendi modus non secum ferat hanc proponendi rationem: O.A est O.B, sed pro hac propositione substituatur O.A est B; convertendo dici potest q.B est A, modo attendatur ad id, quod particularitas comprehensiva et definita sit intelligenda, quæ justo modo extensa potest coincidere cum omnitudine. Si vero exacte loquendum sit, propositio O.A est B distingui debet ab hac O.A est O.B.

"Brevius: O.A est O.B. Si est O.B, præter B nihil aliud datur; adeoque O.B est O.A per conversionem.

"Vel sic: O.A est O.B; hoc est: Omne quod est in A tam ratione comprehensionis, quam extensionis, est quoque in B. A et B igitur nullo modo differunt, adeoque A est B, uti A est A."

§ 44. "Sit propositio particulariter affirmans q.A est B.

"Hic aut q.A est q.B, aut q.A est O.B.

"Priori casu patet, convertendo q.B fore q.A; posteriori autem, O.B esse q.A. Si enim quoddam A est quoddam B; patet ex hypothesi, nec ad omnia A, nec ad omnia B heic respici; adeoque seriem ita esse concipiendam

AB. AB. CB. CB. AD. AD. &c.

" Ex intuitione manifestum est, A et B non semper conjungi, sed tam A quam B cum diversis signis connecti. Ergo q.A — B idem est cum q.B — A.

" Posteriori casu autem sequens apparet facies

AB. AB. AB. &c.

AC. AD. AE. &c.

" Ex hypothesi non datur B, quod non insit τῷ A; adeoque, OB — A, sed tantum quoddam A est cum B conjunctum. *e.g.*, Quidam homo est miles. Non datur miles, de quo non prædicari possit, quod sit homo, adeoque omnis miles est homo, sed tantum idea *cujusdam* hominis connectitur cum idea militis. Sed cum in expressione consueta quantitas prædicati non determinetur; utraque propositio facta conversione habebit subjectum particulare."

It will be seen from these extracts that Ploucquet competently understood the use of a quantified predicate in relation to propositions. Strangely enough, however, he makes no use of it in his treatment of syllogisms, where especially, or rather exclusively, its higher scientific value rises into view. With the exception of two short sentences, (if I remember aright, for I speak only from past reading,) he gives no intimation of its use in relation to syllogisms. These sentences are both notes. The first, which is appended as an exceptional provision to the rule, that from two particular propositions nothing follows, is this:—" Hic tantum agitur de expressione conclusionis consueta, ubi prædicato non addi solet signum quantitativum." The second, which is given at the end of his consideration of the third figure, and is to the effect that valid negative syllogisms may be obtained in it, is as follows:—" Si in propositionibus particulariter negantibus adjiciatur prædicato signum particularitatis; figura hæc procedit in omnibus modis supra recensitis."

This want of anything like a scientific application of the principle to the syllogism may indeed be said to be universal.

None of those to whom we have referred as having partially appreciated it, seem to have been at all aware of its value in relation to the forms of reasoning; but, after having applied it to some particular detail in the treatment of propositions, or at most to some exceptional case of syllogism, appear to have abandoned it altogether.

The promised historical evidence touching the previous partial appreciations of the new doctrine properly terminates here. I cannot, however, close this note without quoting a curious passage from a recent British writer, whose contributions to logical science have not met with the attention which their merit deserves. This writer is Mr. Thynne, who would probably have become better known, but for the comparatively humble form which he has chosen as the vehicle of his logical discussions. These discussions were published in the form of notes to Walker's *Compendium of Logic*, which has been for many years, and, for anything I know to the contrary, still is, the text-book of Trinity College, Dublin. These notes evince a careful study of logic, and an acute comprehension of the science, both in its general scope and in its particular detail; they show also an amount of independent thought in relation to the science, very rarely indeed to be met with in recent logical writings. The paragraph I am about to quote is really a very curious one, on account of its strange prophetic significance. It is given as a note to a passage in the text, in which the author, after giving the common statement that there are in all 64 moods, and that so many are *in*valid, adds, "*accordingly there are* 19 *concluding moods*." The note is as follows:—

"(8) This, as logicians say, is gratuitously assumed. Sufficient has been said by our author to establish that all other modes than these 19 are inconclusive, but nothing has preceded to verify the conclusions in these modes. This may be done by the axioms, even more easily perhaps than by the

famous rules of Aristotle; but in the application of the axioms the distinction of the premises and extremes into major and minor vanishes. If *all men* and *some animals* agree with a third, they agree with *each* other; and it is indifferent whether it be understood that all men are certain animals, or certain animals are all mankind. And it is certain, that if syllogistic reasoning had been thus viewed and followed up, it would be more readily brought into practice, or rather—as it is already, in the general practice of reasoning, thus treated, imperceptibly because enthymematically—it would receive less distinction of mode and figure; and consequently require less rule, and admit of simpler and readier, although not more ingenious, complete, or elegant verification than as at present treated."

This prophetic foresight, however, exercises no beneficial influence on Mr. Thynne's own treatment of the science. Logic certainly receives no simplification at his hands; on the contrary, the whole subject of mood and figure is made, if possible, still more intricate by the ingenious involution and evolution of detail which Mr. Thynne has introduced into its treatment. He therefore does not accept the doctrine he foreshadows. He may be said indeed to have explicitly rejected the quantification of the predicate; for he has propounded a theory of his own in relation to quantification, which is, to say the least of it, of the strangest kind. Mr. Thynne holds that *quantification is an affection of the copula.* This is a confusion so strange and complete, that were it advanced by a less able author, it might be rejected at once. Anything, however, which is seriously urged by so careful a student of logic as Mr. Thynne proves himself to be, is entitled to consideration, and if found to be erroneous, merits at least the courtesy of a refutation.

Mr. Thynne adverts to his doctrine in several of his notes; but the passage in which he most clearly propounds it is the following:—

"Such marks of quantity, although grammatically qualifying

the subject, do in sense qualify the copula; intimating the extent in which the agreement or disagreement of the terms is declared—that this extent is implied to be, either general or partial. 'Every man is an animal' implies that 'man is universally an animal:' 'No man is a stone,' that 'man—is universally not—a stone:' and 'some men are just' that 'man—is in part of the extension—just.'"

On this I would remark generally, that even supposing it to be correct, and that we may thus explain the quantity of the subject, still no account is given of the quantity of the predicate, which on the same principle ought also to be an affection of the copula, and to be represented accordingly in the same manner. Thus, to take the last of the above examples, since this is the only one which is given in the regular form, Mr. Thynne having in effect quantified the predicate in the others by the articles, —this is, "some man is just," which, says Mr. Thynne, is truly expressed thus, "man—is in part of the extension—just;" but whether is this part of the extension of man equal to *all* just or *some* just? This is a pertinent inquiry, for "*just*" is indefinite and must be formally limited or amplified in the same way as the subject. On Mr. Thynne's doctrine, therefore, two parts of extension must be expressed by the copula, in some such manner as the following: "Man—is in part of its extension—just —in part of its extension." All of this on the doctrine in question save *man* and *just* belongs to the copula; in short, Mr. Thynne maintains that the terms of a proposition are always taken *absolutely,* and that all modification of this absolute meaning belongs not to themselves but to the copula. The absurdity of such a doctrine will be better seen from an example in which the modification of the terms is of a more definite numerical kind than that usually found in the ordinary examples; for as *all* modification of the terms, that is, *everything* indicating the extent of the agreement or difference existing between them, belongs to the copula, then necessarily numerical modification

of extent belongs to it also. Take then the following proposition:—"ten horses are equal in strength to a hundred men." This expounded according to Mr. Thynne's doctrine will become the following:—"horse (taken absolutely)—is, considered under the relation of ten—equal to man (taken absolutely) considered under the relation of one hundred: or a part equal in extent to ten taken out of the whole concept horse—is equal in a given relation, that of strength, to wit, to a part equal to a hundred taken out of the whole concept man." The former way of stating it is contradictory enough, and in the latter surely no one will seriously say that the true subject is the *whole concept horse*, and the true predicate the *whole concept man.*

This criticism would be in part inapplicable, did Mr. Thynne, with Aristotle and some of the older logicians, and indeed with the Compendium itself on which he comments,—did he hold, we say, with these, that the copula is included in the predicate. It is manifest, however, partly from his remarks, and abundantly from his practice, that he does not do so, but with logicians in general considers it simply as the bond of connexion between two terms, and in the last resort, therefore, always the substantive verb.

Mr. Thynne gives the following illustration in confirmation of his doctrine:—

"This is not the only respect in which a circumstance grammatically associated with the subject is logically associated with the copula. In the proposition above, 'no man is a stone,' *no-man* is surely not the subject, for the declaration is intended to be made of man, and not of that which is not man: nor is the copula *is*, for the relation is intended to be one of disagreement. The negation therefore is here logically a modification of the copula, although grammatically of the subject."

If the principle was unfortunate, the illustration is certainly equally so. "In the proposition, 'no man is a stone,'" says Mr. Thynne, "*no-man* is surely not the subject, for the declara-

tion is intended to be made of man, and not of that which is not man." Now, what is the declaration made in the above proposition? It must surely be, "*is a stone*," which, says Mr. Thynne, is intended to be made of man, and not of that which is not man, but which I cannot but think notwithstanding is intended to be made of that which is *not man*, since it cannot be truly said that any stone is a man; and accordingly that *no-man* is the subject. Speaking generally, it may be said that in any negative proposition the negation may fall on the subject, on the predicate, or on the copula; but that on whatever member it falls, it becomes truly a part of that member; falling on the subject therefore in the proposition above, *no-man* is the true subject.

Let us look, however, for a moment more closely into the matter. A proposition is but the reflex in language of a judgment; a judgment is the product of a particular mental act. Now, the whole question is determined by ascertaining specifically *what that act is*. It is, in brief, one of *comparison*. Two things (terms of any kind) are compared together in order to ascertain whether they stand to each other in the relation of determining and determined, of whole and part; in a word, to discover what is the extent of their agreement or difference. Now, does this extent of agreement or difference belong to the objects which are compared together, or to the mind which compares them? Surely when two things are compared together, and found to stand to each other in the relation of part and whole, that affection of quantity belongs to the things, and not simply to the mind which perceives them. But on the theory in question the act of judgment is not only *cognitive*, but *creative*; it not only *perceives a relation*, but also *creates the relation which it perceives*. This involves a double confusion; a confusion in philosophy of the *perceiving mind* with the *things perceived*, of the *mental act* with its *object:* a confusion in logic of *quantity* with *quality*, of the *matter* with the *form* of a proposition, of things to be connected with the bond of their connexion. It is

indeed an error so manifest, that we need not dwell upon its refutation, and one which could only have been committed by so able a logician as Mr. Thynne through great haste, or greater oversight.

We have thus the subject of quantification viewed in almost all the aspects in which it can possibly be considered. The common doctrine considers it in relation to the *subject;* Sir William Hamilton as it affects the *predicate;* Mr. Thynne maintains that it is an affection of the *copula;* while Mr. De Morgan (after Lambert) has elaborated a particular quantification of the *middle term.* This last scheme, however, as but a trivial and practically useless refinement on a doctrine universally held by logicians, may be thrown out of account. Mr. Thynne's notion, we have endeavoured to show, must, as the result of a strange confusion, be at once rejected. The subject and predicate, therefore, alone remain to be considered. The quantification of these terms, as the ultimate constituents of logical analysis, is, we need scarcely say, all-important. Through the working out of quantification in relation to the subject, the existing logic has attained to whatever of perfection of detail it can pretend to; through its working out in relation to the predicate, it will attain to the whole perfection of which, as a science, it is susceptible. The former is substantially the work of Aristotle; the latter is equally so that of Sir William Hamilton.

To sum up, then, the evidence we have gained: We have found, on the one hand, that the express quantification of the predicate has been rejected with singular uniformity throughout the entire history of the science. On the other hand, that it has been sometimes partially adopted in theory, and at other times in various ways applied in practice; only, however, to amend some particular detail of the science—it may be to simplify the process of conversion—it may be to modify, by a problematical exception, some particular rule of syllogism. But we have also seen, that its want has never been signalised as a fundamental de-

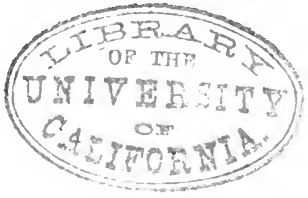
fect in the original logical analysis;—a defect through which the science had been encumbered by unscientific supports—disfigured by unscientific additions—dwarfed by unscientific restrictions, and thus shorn of its true beauty of proportion and completeness; that it has never, therefore, been employed as a principle to reconstruct the whole edifice of the science, and by removing what was useless, rejecting what was false, and supplying what was wanting, to restore it to its perfect and harmonious beauty.

Despite, therefore, the evidence of partial perception which we have adduced, the original statement, "that the principle in its full scientific significance has been altogether overlooked by logicians," is vindicated.

No. II.

ON THE CATHOLIC DOCTRINE TOUCHING THE IMPLICIT QUANTIFICATION OF THE PREDICATE.

Though logicians have with one consent rejected the *explicit*, they have, nevertheless, always held an *implicit* quantification of the predicate. This was indeed absolutely necessary to the existence and working of the science. For since all reasoning is in the last resort but the comparison of two terms with a third term,—but the perception of how far two terms mutually agree or disagree through the perception of how far they agree or disagree with a third,—it is obviously not only important but imperative that the extent of these terms themselves should be taken into account. This is, indeed, the very essence of the reasoning. Apart from this there can be no measurement of extent, and no conclusion of identity or difference of extent as the result of such measurement.



In other words, in any syllogism the process of the reasoning and the evidence of its validity is the same, and it is the following:—the middle term is the mean or measure; in the first place, one extreme is compared with the middle term, and seen to agree with it *so far;* then the other extreme is compared with the middle, and also seen to agree with it *so far;* and thereupon this identity of agreement is affirmed. But, in either case, if I do not know the extent of the term compared, (cannot take it, that is, in some *definite* extent,) I cannot tell *how far* it agrees with the middle. Or, again, if I do not know the extent of the middle term, (cannot take it in some definite extent,) I cannot tell whether the term to be compared agrees with it in extent or not,—whether it is part, or whole, or none. The predicate notion, however, in every reasoning is one of these terms, and stands in one of these relations. It is, therefore, absolutely necessary, as we have said, to the validity of the reasoning, that it should have a *definite quantity;* and a definite quantity, accordingly, it always has had in the science. This quantity, however, instead of being left like that of the subject to reflect itself in language according to the whole extent of its possible variation as an element of formal thought, was made the subject of arbitrary legislation. Logical law enacted that the quantity of the predicate should always be held *particular* in affirmative propositions, and *universal* in negative ones. That logicians by this arbitrary and unjust enactment crippled their science,—crippled it too in a useless and preposterous manner—could be very easily shown. The natural scientific action of one of its parts was at once interfered with; it could only work now under given artificial restrictions—restrictions which had not the slightest shadow of scientific warrant for their imposition. These restrictions are, indeed, not only artificial but capricious, for no reason whatever can be shown why one term of a relation of quantity should be made the subject of arbitrary legislation rather than another. It would have been just as wise

and just as scientific to have laid down arbitrary rules for the quantity of the subject as for that of the predicate. Why not, it may be asked of the logicians, place the subject under the same restrictions, and enact, for instance, that its quantity shall always be held *universal* in affirmative propositions, and *particular* in negative ones?

The whole subject may be illustrated more fully in detail by the use of a figure which we have already partially employed. The subject and the predicate may be said to be the legs on which the syllogism stands. Its free progress, of course, depends on the natural unrestricted action of these members. Logicians have, however, crippled one of these—the predicate—by preventing such natural action. In order, however, that the syllogism might work at all after having been thus maimed, it became necessary to provide some support for the crippled limb. This, accordingly, was found, and in the shape of a body of special rules, a crutch which partially supplied the place of the natural support, was realised. Why did not the logicians, we ask, since they had thus endorsed the principle of such a procedure, destroy the natural action of the other limb also, and provide it with the same artificial support? They would thus have solved the problem, how far the syllogism could proceed when altogether deprived of the native strength of its own members, and supported on *two crutches* instead of one;—an ingenious experiment enough, certainly, but one which bears exactly the same relation to the natural development of the science, that racing in sacks does to the natural exercise of the limbs in walking.

This ingenious problem, however, the logicians have not attempted in its integrity. They have remained satisfied with its partial solution in relation to the predicate. The laws which they have laid down for the regulation of its quantity are, as we have said, two, viz.:—

1°. That in all affirmative propositions the quantity of the predicate is particular.

2°. That in all negative propositions the quantity of the predicate is universal.

On these two axioms, as they are commonly, but of course erroneously termed, the whole detail of the existing logic rests. They have determined its peculiar form and necessitated its special rules. These special rules may indeed be appropriately described as a body of provisions to secure that the predicate is always really taken according to the quantity assigned to it in the axioms. This will be at once manifest by an examination of the demonstrations of those special rules which are sometimes given in logical works. These demonstrations contain of course the reasons on which the rules rest, and these will be found in every case to arise from the necessities of the predicate in relation to its implied quantity. We quote the following in illustration from the Port Royal Logic, where all the special rules are briefly but adequately explained.

"RULES OF THE FIRST FIGURE.

"*The minor must be affirmative;*

"For, if it were negative, the major would be affirmative by the third general rule, and the conclusion negative by the fifth; therefore the *greater term* would be taken *universally in the conclusion,* since it would be negative, and *particularly in the major;* for it is *its attribute* in this figure, and would be affirmative, thus violating the second rule, which forbids us to conclude from the particular to the general. This reason holds also in the third figure, where the greater term is also attribute in the major.

"*The major must be universal;*

"For, the minor being affirmative, by the preceding rule, the *middle term, which is its attribute, is taken particularly;* therefore it must be universal in the major, where it is subject, which renders this proposition universal; otherwise it will be taken

twice particularly, contrary to the first general rule."—Pp. 189, 190.

"FIRST RULE OF THE SECOND FIGURE.

"*One of the two propositions must be negative, and consequently the conclusion also, by the sixth general rule;*

"For, if both propositions were affirmative, *the middle, which is here always attribute, would be taken twice particularly*, contrary to the first general rule."—P. 193.

The necessity of these special rules is manifest, for of those of the first figure, if the *former* were violated, a term which, as the predicate of an affirmative proposition, was *particular* in the major premise, would, as the predicate of a negative proposition, become *universal* in the conclusion; if the *latter* were violated, the middle term would, as predicate in the affirmative minor premise, be *particular* there, as well as in the major, and thus remain *undistributed*. The same reason holds in the first rule of the second figure. The other special rules are susceptible of a similar explanation, as may be readily tested, by taking them and the two axioms of quantity, and working out the relation of determination which exists between them. These axioms are thus, as we have said, operative through the whole detail of formal reasoning, as it stands in the existing logic. Rejecting the *explicit*, and accepting only the *implicit* quantification of the predicate, the question to be determined by logicians was, —how many of the possible forms of reasoning are valid without such explicit quantification? The commonly accredited syllogisms were the result of this examination. The special rules which protect them were generalisations from the causes which rendered the rest invalid. Those which severally, according to their figure, obeyed the conditions of these rules, were alone accepted. These reasonings were declared, moreover, not only to embrace all the valid syllogisms which could be obtained under such restrictions, but also to exhaust all the possible forms

allowed by the laws of thought. This is, indeed, one of the grounds expressly taken by Pacius in his rejection of a quantified predicate. He says, (at the close of the second of the extracts given from him earlier in the Appendix,) that the quantification of the predicate is of no use to the syllogism,—that it does not at all aid its validity; and gives a syllogism in Barbara of the first figure in illustration of his statement. The answer to this is easy. The express quantification of the predicate will not, of course, help the validity of those syllogisms which have been expressly constructed so as to be independent of its aid; and the cogency of which, therefore, is complete without such quantification. All the syllogisms of the existing logic are of this kind; and their validity, accordingly, is independent of any such expressed quantity. But this does not at all prove, on the one hand, that even these would not possess a higher formal completeness with the quantity of the predicate expressed; or on the other hand, that there may not be *other syllogisms* whose validity entirely depends on such expressed quantity. This is indeed the case; for on the one hand, everything of force in a formal science ought to be formally expressed; and on the other, *there are* a number of forms of reasoning guaranteed by the laws of thought, whose validity is not only contributed to, but *constituted by*, the expressed quantity of the predicate. Looked at therefore from the lower ground of the axioms of quantity, and the reasonings possible through them, the expressed quantity of the predicate is not absolutely necessary; but, regarded from the higher ground of the laws of thought, and their scientific development, this quantification is not only imperative, but indispensable.

These so-called axioms of quantity, it may be worth while to notice, are but corollaries from the laws laid down touching regular predication; for if the only lawful predication is that in which a genus is predicated of its species, since the genus is always of wider extent than its species, when so predicated it can

only be taken in *some part* of its whole extent, that is say *particularly*. Again, if it be unlawful to affix marks of quantity to the predicate, we cannot deny *some part* of a genus of one of its species; and all negative propositions must therefore contain repugnant species or genera, which will accordingly be denied of each other in their *whole extent*. The rules for predication, and those for the quantity of the predicate, thus at bottom imply each other. It would perhaps be difficult to say which were cause and which effect; or rather, it would probably be nearer the truth to say, that they are both the result of the same defective analysis and want of scientific insight. Out of this original defect have arisen, as we have shown, the complexity, the restriction, and the disorder, of which the special rules, and the syllogisms they indorse, are at once the evidence and the result.

The simplicity of the reasoning process, contrasted with the complexity of the rules devised for its guidance and protection, could hardly, however, fail to arrest the attention of some of the many thinkers who have from time to time undertaken their exposition. They accordingly have, in various ways, betrayed their sense of the want of thorough scientific simplicity and completeness which these rules indicated: some, as we have seen, by falling upon stray syllogisms which violated the rules, but which were nevertheless quite valid, without, however, being able to offer any theoretic explanation of the fact: others, again, by simplifying the syllogistic law in theory, without being able to show how this theoretical simplification could be realised in actual practice. A curious instance of this latter kind occurs in the Logic of Caspar Wyss, which was published at Geneva (where he was for some time Professor) in the year 1669. He reduces all the rules of syllogism, both the *general* and the *special*, to the single one, *that every syllogism should have three and only three terms*. We subjoin his reduction of the special rules as a specimen of the way in which he accomplishes this:—

" *De Regulis specialibus Syllogismorum.*

" Regulæ speciales syllogismorum sequentes pronuntur a Philosophis : I^a. *Regula specialis* est : *In prima figura, major debet esse universalis.* Unde hic syllogismus non valet : Omnis homo non est in hac urbe ; Tu es homo ; E. tu non es in hac urbe. Item : Omne animal non est rationale ; Sed homo est animal ; E. homo non est rationalis.

" Verum contra hanc regulam dici potest, illam non esse universaliter veram ; si enim tollatur ambiguitas, et sint tantum tres termini in syllogismo, syllogismi primæ figuræ, ex majori particulari, sunt legitimi : v. g. Aliquod animal est rationale ; Homo est animal ; E. homo est rationalis. Quare dicendum est : syllogismos superius allatos esse vitiosos, quia in iis dantur quatuor termini. In priore enim syllogismo, homo aliter sumitur in majore, quam in minore. In posteriore vero, animal aliter sumitur in majore, quam in minore, ut patet attendenti.

" II^a. *Regula specialis* est : *In prima figura, minor debet esse affirmata.* Unde hic syllogismus non valet : Omnis asinus est animal ; Sed homo non est asinus ; E. homo non est animal. Item : Omne rationale est animal ; Solus homo est rationalis ; E. solus homo est animal.

" Verum contra hanc regulam, dici potest, illam non esse universaliter veram, eo, quod dentur syllogismi primæ figuræ, ex minore negata, qui sunt legitimi : v. g. Qui non credit in Christum damnabitur ; Sed reprobi non credunt in Christum ; E. reprobi damnabuntur. Quare *dicendum* est, syllogismos primæ figuræ, ex minore negata, esse legitimos, si sint tantum tres ter-

mini; esse vero vitiosos, si sint quatuor termini, ut patet in syllogismis superius allatis, in quibus sunt duo media, adeoque quatuor termini. Nam in priore, asinus est medium in majore, non asinus vero, est medium in minore. In posteriore vero syllogismo, rationale est medium in majore, non rationale vero, est medium in minore. *Adde*, quod in ejusmodi syllogismis, animal aliter sumatur in majore, quam in conclusione, ut patet attendenti.

" III^a. *Regula specialis* est: *In secunda figura, major debet esse universalis.*

" Verum contra hanc regulam dici potest, syllogismos secundæ figuræ ex majore particulari esse bonos, si sint tantum tres termini, non æquivoci; esse vero vitiosos, si sint quatuor termini, sicut diximus, de syllogismis primæ figuræ; adeoque hæc regula, est superflua.

" IV^a. *Regula specialis* est: *In secunda figura, altera præmissarum debet esse negans;* juxta illud vulgatum: ex puris affirmantibus, in secunda figura, nihil concluditur. Quare hic syllogismus non valet: Asinus est animal; Sed homo est animal; E. homo est asinus. Item: Asinus habet aures; Tu habes aures; E. tu es asinus.

" Verum, contra hanc regulam dici potest, illam non esse universaliter veram, cum multi sint syllogismi recti, in secunda figura, ex puris affirmantibus: v. g. Omne rationale est risibile; Omnis homo est risibilis; E. omnis homo est rationalis. Item: Omne brutum est animal; Omnis asinus est animal; E. omnis asinus est brutum. Quare *dicendum* est, ex puris affirmantibus, in secunda figura recte concludi, si sint tantum tres termini;

male vero concludi, si sint quatuor termini, ut patet in syllogismis vitiosis superius allatis. In priore enim, animal aliter sumitur in majore quam in minore; in majore enim, sumitur pro animali contracto ad asinum, in minore vero, pro animali contracto ad hominem. In posteriore vero syllogismo, medium, scilicet aures, aliter sumitur in majore ac in minore. In majore enim, aures sumuntur pro auribus asininis; in minore vero, pro auribus humanis.

" V^a. *Regula specialis* est: *In tertia figura, minor debet esse affirmata.*

" Verum, contra hanc regulam dici potest, syllogismos tertiæ figuræ, ex minori negante, posse esse rectos, modo, non sint quatuor termini, et nullus terminus sit æquivocus, sicuti diximus de syllogismis primæ figuræ; atque adeo hæc regula est superflua.

" VI^a. *Regula specialis* est: *In tertia figura, conclusio debet esse particularis:* Unde hic syllogismus non valet: Omnis homo est rationalis; Omnis homo est animal; E. omne animal est rationale.

" Verum, contra hanc regulam dici potest, syllogismos tertiæ figuræ, conclusionem universalem habentes, esse rectos, modo, sint tantum tres termini non æquivoci. In syllogismo autem, superius allato, sunt quatuor termini, eo, quod animal aliter sumatur in conclusione, aliter vero in minore. Quod si, animal, in conclusione sumatur eodem modo ac in minore, scilicet pro animali identificato cum homine, conclusio erit vera, omne scilicet animal, identificatum cum homine, esse rationale; et sic, syllogismus erit rectus, ut patet attendenti.

" Ex his omnibus *patet:* omnes regulas syllogismorum, esse superfluas, hac unica excepta, *in syllogismo, debent esse tantum tres*

termini, non plures, nec pauciores; et per consequens, omnia sophismata, ad unum posse revocari, scilicet ad sophisma ab æquivocatione." *Logica C. Wyssii.* Genevæ, 1669, pp. 318-321.

All that is here said touching the certainty of obtaining valid syllogisms, if we only avoid having more than three terms, is quite true; but the question arises, *how* are we, under the existing syllogistic forms, to avoid having more than three terms? The answer is more simple than satisfactory. It is, by observing those very precautions which the special rules enjoin;—in other words, by recalling in practice the code which had been theoretically abolished. The reduction of the special rules is so far just, but not a single step is thus taken towards relieving the science in its practical working from the necessity which imposed them. This could only have been done by the express quantification of the predicate, without which, indeed, many of the syllogisms given by Wyss in his reduction are formally worthless, but of which he does not seem to have had a glimpse.

No. III.

ON FIGURE.

THE opinions which have been from time to time held by logicians touching the nature and value of the Figures, (that is to say, of the second and third,) seem to have been very fluctuating, if not inconsistent and even contradictory. Some have maintained their independence as separate forms of reasoning. Others, again, and these are the great majority, have maintained, that whatever value they possess is reflected on them from the first figure, and thus solely derived from their connexion

more or less direct with it. Of the former, some inconsequently retained the doctrine of *reduction*, and thus neutralised by a vicious practice their purer faith; a few, again, altogether rejected it; while Valla (abolishing the third) even proposes to reduce the moods of the first figure to those of the second. Then, again, with regard to the *different members* of the syllogism in these figures, opinions seem to have been almost equally divided. The great majority maintained that the syllogisms in these figures had a determinate *major* and *minor* premise, and consequently a single determinate conclusion. Others, again, could see no grounds sufficiently decisive on which to establish such certainty of premise, and held, as Apuleius and Valla, in certain cases, two conclusions. The former, however, while at one in their belief, are by no means unanimous as to the grounds on which they vindicate a determinate major and minor premise to these figures. They all agree, of course, that the major premise is that in which the *major term* is found. All the difficulty lay in discovering the major term; and the ways in which this was attempted to be done are, so far as I have met with them, of the most inconsequent and assumptive kind.

Sometimes the *major* term was held to be the predicate of the question, or rather the term occupying the predicate place in the question, that, to wit, touching which the doubt arises; for example, if it were inquired whether man were a stone, *stone* would on this doctrine be the major term. Sometimes, again, the major was held to be the term which was first enounced; and often enough a major term was conveniently postulated through the arbitrary assumption of a major premise. The methods, indeed, by which it has been attempted to vindicate determinate members to the syllogisms of these figures, all resolve themselves, in the last resort, to *a begging of the question.* This was generally done in one of two ways; either a determinate conclusion was begged in order to establish determinate premises, or determinate premises were

begged in order to obtain a single determinate conclusion. I had intended to have gone into this whole question at some length historically, and for this purpose had marked a number of references in various logical writers; but though those are numerous and varied in character, I do not feel that I am by any means in possession of sufficient evidence to determine historically what the catholic doctrine in relation to the above points really was. I have accordingly thrown them aside, and must for the present leave the statement given in the body of the work as it stands.

One thing, however, is plain; that from the earliest to the latest times the procedure of the other figures was felt to be less direct, and their conclusion less authoritative than those of the first. To rectify this imperfection two processes have been devised. The first—that of *Reduction*—is of old date in the science, and is that usually practised by the logicians; the second —which may be termed that of *Exposition*—is comparatively new; for though anticipated in some of its details, it is substantially Kant's.* This process is that briefly expounded and applied in the text. These two processes have this much in common—that they accomplish their end by the transposition and conversion of propositions. In the former, however, the change made in the proposition is accomplished by formal conversion, in the latter by real inference. Of *reduction* we have already spoken in the Essay, and need not dwell upon it again here. With regard to the process of Kant, it is itself as tedious and involved as are the reasonings which it is employed to explicate. It is at best but a round-about way of accomplishing what perhaps there is no need for doing at all. The new doctrine, in-

* Kant first expounded this speculation of his in a tract published in 1762, and entitled, "*The false Subtilty of the Four Syllogistic Figures Demonstrated,*" (Die falsche Spitzfindigkeit der vier Syllogistischen Figuren erwiesen.) This is, I believe, republished with Kant's Logic, in the French translation of that work by M. Tissot.

deed, does away with the necessity or usefulness of any such process. On that doctrine this exposition is itself expounded, and this abolition of the figures itself abolished:—figure appears in its true character as an unessential variation of syllogistic form; the several figures remain in their integrity with whatever of special value they ever possessed, while the essential form of the reasoning, when fully stated, is manifest through all the accidental positions of its constituent elements. The same reasoning may be given in either of these accidental varieties of position; but since it obviously appears as essentially *one*, its cogency remains the same, and reduction and exposition are therefore equally vain and useless.

No. IV.

ON NOTATION.

The notation employed in the text is that of one of the systems devised by Sir W. Hamilton, in order to represent to the eye the various possible forms of reasoning by distinctive symbols. It has all the virtues of a perfect notation. It is simple, distinctive,* perspicuous, and complete. It can represent *any*

* That it be *distinctive* is a virtue of first account in any system of logical notation; for to borrow the accredited signs of any other science is on every account to be avoided. I need scarcely say, therefore, how earnestly I unite with Mr. Mansell in deprecating "that mathematical method of exposition," which is, as he truly says, in relation to logic, "alike injurious to the science and repulsive to the learner."

The introduction of mathematical symbols and methods of working into logic is indeed, on every account, to be protested against by all who are interested in the welfare of the science. The rejection of these is the more to be insisted on, as well-meaning efforts still continue to be made to improve logic by mathematical treatment, if not indeed to afford it mathe-

relation of the terms, *any* order of the propositions, *any* extent of quantity. The letters represent the terms, the points their quantity, and the lines with the letters the propositions. The letters express, by position to the eye, the relation which the terms have in thought, the middle being placed between the extremes. The meaning of the *points* has been already explained; the *colon* denotes *universal* quantity, "all;" the comma *particular* quantity, "some." Of the lines the shorter denote the premises, the longer the conclusion; the thick end denotes the *subject*, the thin end the *predicate*. Thus the first syllogism given in the table would read as follows:—

All B is all A.
All C is all B. Therefore,
All C is all A.

Negative propositions are marked by crossing the copulative line on which the negation falls, as shown in the *premises* of the negative syllogisms given in the table. I may here notice that the cross is absent from the lines of conclusion in these syllogisms by accident, and not by design. It was omitted in the cutting of the type; and I must request the reader to be good enough to supply it by the pen.

This system of notation will now probably be generally known to logical students through the exposition of it given by Mr.

matical protection. With all such help, however, it can well afford to dispense; if it could not—indeed, if this were not to it hindrance rather than help—it would have no claim to rank as a separate science. The notion of extending the sphere of mathematics so as to include logic, is as theoretically absurd as its realisation is practically impossible. To identify logic with mathematics is to make the whole equal to its part: while to subordinate the former to the latter is to increase the marvel, by making the whole less than its part. And those who, without attempting this, display their skill by translating logical forms into mathematical language, accomplish a work just about as useful and praiseworthy as that "of the two zealous, but thick-headed logicians—Herlinus and Dasypodius by name—who rendered the first six books of Euclid into formal syllogisms." All such endeavours possess the singular merit of making logic as repulsive as possible, without doing the least service to mathematics.

Thomson in his "Outline of the Laws of Thought," where further details respecting it may be found. Mr. Thomson says, in introducing his explanation, that "many of the different elements of the notation are not new." With all respect for the statement of so careful and zealous a student of logic as Mr. Thomson, I must say I cannot but think that this is a mistake. I do not know, of course, what authority Mr. Thomson may have for his statement; but, with some general knowledge of most of the previous systems of logical notation which have been employed, I cannot recall any which anticipate the present, either in notion or detail; unless, indeed, the bare use of lines, though in a totally different manner, can be said to do so. I cannot think, however, that this is what Mr. Thomson refers to; for the *linear notation* is a separate system, altogether distinct from the one in question.

I had intended to have introduced here fuller tables, running the positive and negative syllogisms through *all* the figures, as well as some specimens of other systems of notation which Sir William Hamilton has kindly placed at my disposal. I am not without hope, however, that Sir William will himself publish them in full before very long; and I need scarcely say, therefore, how gladly I relinquish their partial introduction here. I know how earnestly all who are interested in logical science will unite with me in the hope that Sir William Hamilton's health and leisure may be such as to enable him to carry through the press at no distant interval some portion of his promised work.

NOTE BY SIR WILLIAM HAMILTON.

The following note contains a summary of my more matured doctrine of the Syllogism, in so far as it is relative to the preceding Essay.

All *mediate* inference is one—that incorrectly called *Categorical;* for the *Conjunctive* and *Disjunctive* forms of *Hypothetical* reasoning are reducible to immediate inferences.

Mentally one, the Categorical Syllogism, according to its order of enouncement, is either *Analytic* or *Synthetic.* Analytic, if (what is inappropriately styled) the conclusion be expressed first, and (what are inappropriately styled) the premises be then stated as its reasons. Synthetic, if the premises precede, and, as it were, effectuate the conclusion. These general forms of the syllogism can with ease be distinguished by a competent notation; and every special variety in the one has its corresponding variety in the other.

Taking the syllogism under the *latter* form, (which, though perhaps less natural, has been alone cultivated by logicians, and to which, therefore, exclusively all logical nomenclature is relative,)—the syllogism is again divided into the *Unfigured* and the *Figured.*

The Unfigured Syllogism is that in which the terms compared do not stand to each other in the reciprocal relation of subject and predicate, being in the same proposition, either both subjects or both predicates. Here the dependency of Breadth and Depth, (Extension and Intension, Extension and Comprehension, &c.,) does not subsist, and the order, accordingly, of the premises is wholly arbitrary. This form has been overlooked by the logicians, though equally worthy of development as any

other; in fact, it affords a key to the whole mystery of Syllogism. And what is curious, the canon by which this syllogism is regulated, (what may be called that of logical Analogy or Proportion,) has, for above five centuries, been commonly stated as the one principle of reasoning, whilst the form of reasoning itself, to which it properly applies, has never been generalized. This canon, which had been often erroneously, and never adequately enounced, in rules four, three, two, or one, is as follows:—*In as far as two notions,* (notions proper or individuals,) *either both agree, or one agreeing, the other does not, with a common third notion; in so far, these notions do or do not agree with each other.*—The propositions of this syllogism in no-figure are marked in the scheme of pure logical notation by horizontal lines of uniform breadth.

In the Figured Syllogism, the terms compared are severally subject and predicate, consequently, in reference to each other, containing and contained in the counter wholes of Intension and Extension. Its canon is:—*What worse relation of subject and predicate subsists between either of two terms and a common third term, with which one, at least, is positively related; that relation subsists between the two terms themselves.*—In the scheme of pure logical notation a horizontal tapering line marks this relation; the subject standing at the broad, the predicate at the pointed end.

There are *three*, and only three, Figures—the same as those of Aristotle; and in each of these we may distinguish the orders of Breadth and of Depth.

The *First* Figure emerges, when the middle term is subject of the one extreme and predicate of the other; that is, when we pass from the one extreme to the other, through the middle, in the order whether of Extension or of Intension. In the notation of this Figure, we may of course arbitrarily make either of these orders to proceed from left to right, or from right to left; that is, two arrangements are competent.—There is here, determinately, one direct and one indirect conclusion.

The *Second* Figure arises, when the middle term is the predicate of both extremes; the order of Breadth proceeding from middle to extremes, the order of Depth from extremes to middle.

The *Third* Figure is determined, when the middle term is the subject of both extremes; the order of Extension proceeding from extremes to middle, the order of Intension from middle to extremes.

In the Second and Third Figures there is thus only one arrangement possible in logical notation. And as Extension and Intension are here in equilibrium, there is no definite major and minor premise, and consequently no indirect, but two indifferent conclusions.—This is best marked by two crossing lines under the premises, each marking the extreme standing to the other as subject or as predicate.

Of course each Figure has its own canon, but these it is not here requisite to state. The First Figure, besides its more general canon, has also two more special,—one for Syllogisms in the order of Extension, and one for Syllogisms in the order of Intension. And what is remarkable, Aristotle's *Dictum de Omni*, &c., (in the Prior Analytics,) gives that for Extension, whilst his rule—*Prædicatum prædicati*, &c., (in the Categories,) affords that for Intension, although this last order of Syllogism was not developed by him or the logicians;—both inadequately.

In regard to the *notation of Quality* and *Quantity* in the syllogisms unfigured and figured:—Negation is marked by a perpendicular line, which may be applied to the copula, to the term, or to the quantification.—As to Quantity, (for there are subordinate distinctions,) it is sufficient here to state, that there is denoted—by the sign [⁘ or ⁘] (for the quantity of one term ought to face the other), *some*;—by the sign [∴], *all*;—by the sign [·], *a half*;—by the sign [⁝ or ⁝], *more than a half*. The last two are only of use to mark the *ultra-total* distribution of the middle term of a syllogism, between both the premises, as affording a certain inference, valid, but of little utility. This I

once thought had been first generalized by me, but I have since found it fully stated and fairly appreciated by Lambert, to say nothing of Frommichen.

Above (p. 76) is a detail of my pure logical notation, as applicable to the thirty-six moods of the first figure. The order there is not, however, that which I have adopted. The following is my final arrangement, and within brackets is its correspondence with the numbers of that given above:—The moods are either A) *Balanced*, or B) *Unbalanced*. In the former class both *terms* and *propositions* are balanced, and it contains two moods—i; ii, [=i; ii.] In the latter class there are two subdivisions. For either, a) the *terms* are unbalanced,—iii, iv, [=xi, xii]; or, b) both the *terms* and *propositions* are unbalanced, —v, vi; vii, viii; ix, x; xi, xii, [=vii, viii; iii, iv; v, vi; ix, x.] The following equation applies to my table of moods given in Mr. Thomson's Laws of Thought:—i; ii; xi, xii; vii, viii; iii, iv; v, vi; ix, x.—The present arrangement is also more minutely determined by another principle, but this it is not here requisite to state.

If we apply the moods to any *matter* however abstract, say letters, there will emerge *forty-two* syllogisms; for the formal identity of the balanced moods will then be distinguished by a material difference. On the contrary, if we regard the mere *formal* equivalence of the moods, these will be reduced to *twenty-one* reasonings,—*seven affirmative*, and *fourteen negative*. Of the balanced moods, i and ii are converted each into itself; of the unbalanced, every odd, and the even number immediately following, are convertible; and in negatives, the first and second moods (*a*, *b*) of the corresponding syzygy or jugation, is reduced from or to the second and first moods (*b*, *a*) of its reciprocal.

There are no exceptions. The canon is thorough-going. Only it must be observed: that the doctrine is erroneous which teaches, that a universal negation is not a *worse* relation than a particular; and that the identity of a negative with an affirma-

tive mood, is regulated exclusively by the identity in *quantity* of the two syzygies or antecedents. The Greeks, in looking to the conjugation of the premises alone, are more accurate than the Latins, who regard all the three propositions of a syllogism in the determination of a mood.

It is not to be forgotten, that as the correlation of the logical terms ought to be known only from the expression, (ex facie propositionis aut syllogismi,) for all other knowledge of the reciprocal dependence of notions is contingent, material, and extralogical; and as the employment of letters, following upon each other in alphabetical order, may naturally suggest a corresponding subordination in the concepts which they denote: I have adopted the signs C and Γ, which are each the third letter in its respective alphabet, for the extremes; and the sign M, for the middle term of the syllogism. The scheme is thus emancipated from all external associations, and otherwise left free in application. I also transpose the former symbols in the interconvertible moods; so that whereas in the one stand C M Γ, in the other stand Γ M C.

PORT-ROYAL LOGIC.

In 12mo, cloth, price 5s. 6d.,

LOGIC; OR, THE ART OF THINKING.

BEING THE PORT-ROYAL LOGIC.

Translated from the French. With an Introduction.

By THOMAS SPENCER BAYNES.

"This work possesses nearly every quality desirable in a text-book, and, in this point of view, stands in remarkable contrast to the feeble, superficial, and incomplete compilations with which even our best schools of learning have hitherto been contented. There have been two previous translations into English, but the present is the only trustworthy one. We have to express our entire satisfaction with the manner in which Mr. Baynes has discharged his duty, and to express the hope that a gentleman who can write so well as he has done in his introductory essay, may soon appear before the public again in the character of author." *Critic.*

"With regard to this translation we need say little. The ability, accomplishments, and competence of Mr. Baynes are a sufficient guarantee for its accuracy. We have examined several parts of it, and can freely affirm, that the terseness and precision of the original are admirably preserved in the translation. The manner in which the publishers have performed their part is every way worthy of the work itself. We would, therefore, earnestly recommend this treatise to all who are desirous of acquiring habits of accurate thinking. No modern work in English with which we are acquainted is at all so well adapted to secure this end—Whately not excepted. We trust, then, that the success of this book will be proportioned to its merits; and, in parting with Mr. Baynes, we would express our hope that he will ere long favour us with other similar contributions from his pen, which are at present so much needed in this country, and for which his acute philosophical powers and great stores of knowledge so well qualify him." *Edinburgh News.*

"The Port-Royal Logic, though familiar to the more advanced logicians of this as of other countries, and appreciated by them as it deserves to be, has not hitherto met with an English translator capable of doing, or who has done, anything like justice to the work. Mr. Baynes has a freedom and power which could only have been achieved by one fully conversant, not only with both the languages he has to deal with, but the subject of which the book treats; while we instinctively feel the rendering to be faithful, without necessity for reference to the original, from its reticence of that idiomatic spirit which so pleasantly introduces us to the individualities of its authors, without that undue deference to the mere idiomatic form which might have painfully obtruded on us continually that they were men of another country and another era."

Caledonian Mercury.

"The translation is evidently the product of an accomplished scholar and an expert logician—who has done good service to the cause of mental improvement by the publication of this volume, appropriately dedicated to Sir William Hamilton, Professor of Logic and Metaphysics in the University of Edinburgh, to whose kind encouragement the author expresses many obligations."

Glasgow Constitutional.

"We have much pleasure in commending this volume to the favourable notice of students and intelligent general readers; and have to bear testimony to the accuracy, spirit, and elegance with which the translation is effected."

Scottish Press.

"Mr. Baynes has performed a welcome service to the student. The Port-Royal Logic needs no commendation from us; and this neatly-printed translation of it will contribute, we trust, to make it better known to the youth of the country." *British Quarterly Review.*

Sutherland & Knox, Edinburgh; Simpkin, Marshall, & Co., London.

MR. M'COSH ON THE METHOD OF THE DIVINE GOVERNMENT.

In the Press, Second Edition of

THE METHOD OF THE DIVINE GOVERNMENT,

PHYSICAL AND MORAL.

By the REV. JAMES M'COSH, A.M.

"Aloof from any difference of opinion, and though I have as yet only read the work in part, it appears to me worthy of the highest encomium, not only from the excellence of the intention, but for the ability with which it is executed. It is refreshing to read a work so distinguished for originality and soundness of thinking, especially as coming from an author of our own country." *Sir William Hamilton, Bart.*

"In the writer of this work we meet with a man of extraordinary calibre, alike remarkable for the vigour and originality of his thinking—for the fine taste and freshness of his writing—for the extent of his learning, and the breadth and minuteness of his acquaintance with those sciences which, from the circumstance that they are prosecuted with avidity by the greater minds of the age, impart, more than the others, colour and tone to the age's thinking. Mr. M'Cosh's work is of the compact cast and thought-eliciting complexion, which men do not willingly let die; and we promise such of our readers as may possess themselves of it much entertainment and instruction of a high order, and a fund of solid thought which they will not soon exhaust." *Witness.*

"To the great task which he has thus set himself, Mr. M'Cosh has brought great powers and ample resources. He is evidently a man of a profoundly philosophic spirit, and at the same time a man of extensive and varied culture in science and literature. His philosophic reading seems to have been very extensive, embracing not only all the better authors in theological, metaphysical, and ethical science, but also the most approved writers on the various branches of physical speculation. He combines with this a power of independent thinking and original speculation which enables him to move easily under the accumulated mass of his learning, and at the same time to apply what he has learned from others to purposes of his own. Perhaps, for most readers, less copiousness of matter, and greater condensation and point in respect of argumentation, would have been an advantage, as it requires considerable previous familiarity with the subject to be able always to find the author's bearings in the extensive field he has selected for exploration. To others, however, who desire not merely to gather a result, but also to witness the process by which the author has himself advanced to it, the plan Mr. M'Cosh has followed will have its charms; whilst for those who find it somewhat difficult to follow him, the summaries he has given at successive stages of his argument will, doubtless, prove serviceable. We may add, that he possesses an enviable power of apt and striking illustration, by which he is enabled both to relieve the attention and facilitate the comprehension of the reader in the abstruse parts of his book."
British Quarterly Review.

LIBRARY OF THE UNIVERSITY OF CALIFORNIA.

PREFACE.

LITTLE more will be expected from a work of the following description, than that it should contain an intelligible and concise exposition of those facts and principles which form, as it were, the groundwork of logical science. Necessarily, therefore, it must be, for the most part, a compilation of such views as have obtained general acceptance, and can lay but little claim to any high degree of originality.

At the same time, I may be permitted to state that some features exist which serve to distinguish this Treatise from its numerous predecessors, and which will, I hope, prove of service to the student by inciting him to examine for himself such theories and principles as come under his notice. Those features to which I more particularly allude, are the reference of all so-called "Immediate Inferences" to the class of syllogisms; the grounds for an extended adoption of Aristotle's *Dictum;* the refutation of the charge that every syllogism involves a *petitio principii;* the explication of the inductive theory in Applied Logic; and, finally,

the doctrine of classification, by which every detail and branch of Logic is shown to exist in harmonious unison. And as these views are, in a measure, opposed to those contained in works of great repute, I have appended to the body of this Treatise four Articles, wherein are set forth such arguments as I think sufficient to justify me in advancing the above-mentioned doctrines.

I also deem it advisable to state that it has been my endeavour to give this work as *suggestive* a character as possible; and, therefore, although it belongs to a rudimentary series, professing to treat only upon the first elements of Logic, I am yet not without hope that it will be found a sufficient introduction to such comprehensive and elaborate treatises as those of Mr. Mill, Professor De Morgan, and others. But while I have thus been compelled to satisfy myself in many cases with an enunciation rather than with a full investigation of certain doctrines, I still trust that, in the following pages, the student will find all that is really requisite to give him a fair, practical knowledge of Logic.

The chapter on Applied Logic is, I am sensible, but a mere sketch. As, however, to do justice to so vast a subject would require a great extension of the present limits, and would thus curtail the utility of this Treatise by enhancing its price, I have contented myself with directing the student's attention to such points as are most important, both in theory and practice. For the same reason, nothing beyond the bare outlines is given of such new doctrines as I have here

adopted; all further development of them being deferred to a future occasion.

I take this opportunity of acknowledging my many and great obligations to those writers upon Logic whose works I have consulted; and although it may seem invidious to particularise, yet as, for reasons which will be found specified in their proper place, I have expressly referred to Mr. John Stuart Mill, as being the advocate of certain opinions which are combated in the following pages, I think it only just that I should here record my admiration for the profound philosophy and great attainments which are so apparent in the writings of that gentleman.

LOGIC.

INTRODUCTION.

Logic may be not inaptly described as the grammar of thought; that is to say, it reveals and explains the principles according to which our judgments are formed, in much the same manner as grammar analyses the laws which regulate the expression of our thoughts by means of speech. It will, therefore, be seen that Logic is a science of universal extent, inasmuch as wherever any process of reasoning is carried on, there will be found, in full operation, those mental laws which it is the office of Logic to examine and systematise. It does not, however, follow that every person who reasons is a logician, for it is only when a process of judgment is carried on in regular order, and according to the rules derived from a study of the science, that such an appellation could be justly bestowed. And, in like manner, it would be absurd to suppose that there can be no correct reasoning without a good knowledge of Logic; for, in order to perceive the error of such a view, we have only to consider for a moment the mode in which every science is formed. Take, for example, the science of astronomy: the heavenly bodies had been urged through space, by the operation of definite cosmical laws, for ages previous to the discovery of those laws by human philosophers, and it was the very fact of such motions being in progress, which led to the investigation of the principles concerned.

Thus, too, with regard to Logic: men had thought and reasoned according to certain laws, long before Aristotle, by observing and reflecting upon the various judgments which came under his notice, was able to enunciate the great fundamental truth upon which they were based. It is from considerations such as these that we speak of scientific *discoveries*, and not of scientific *inventions;* for the latter term can only be applied to some *new method of accomplishing* a specific object, while the former is always used when we speak of any fresh *law or principle*, which, previously existing, has been brought to light by the exertions of the philosopher. Like, then, as Newton discovered gravitation, so did Aristotle discover the syllogism; and, therefore, the notion that the use of the syllogism is merely *one method* of reasoning, is at once shown to be altogether erroneous. The truth is, that there can be *no other* process of forming a judgment, since every conceivable example of reasoning may, by the application of certain rules, be reduced to the syllogistic form.

From what has now been said, the true value of Logic will be easily discerned, and as its subject is one which lies at the root of all other sciences, its importance can hardly be overestimated. Its principal use is that it enables us to reason correctly, by furnishing us with various rules and standards wherewith to test the validity of any argument that may be brought before us. And here it is requisite to guard against a very prevalent misconception; I allude to the idea, that, by means of Logic, one may ascertain the *truth or falsehood* of any statement. The source of this error is to be found in the supposition that Logic is concerned with the *subject* of the various statements (technically, propositions) whose relations to each other it investigates; whereas, in reality, it merely considers their *form*. Thus, the two propositions, "Water is a fluid," and, "Evil is good," would by a logician be considered as precisely similar, although one of them is false,

and the other true. Again, the following argument or syllogism—

All fluids are poisonous,
Water is a fluid;
Therefore Water is poisonous,

is perfectly valid and correct, although the conclusion arrived at is false. To render this point quite plain and intelligible, let us adopt the following course: it was above stated that Logic merely considers the *form* and not the *subject* (or *matter*) of propositions; accordingly, for all logical purposes, we shall not alter the nature of the propositions employed, if we substitute letters for the words we used to express the substances or notions of which we spoke. Thus, instead of "water is a fluid," let us say "A is B," and for "evil is good," let us put "C is D:" we then see at once, that in both instances we use exactly the same kind of proposition. Again, let us similarly convert the syllogism: we have—

All A's are B,
C is an A;
Therefore C is B;

an argument which remains unalterable in *form*, no matter what ideas are expressed by the letters.*

This it is which confers such rigorous accuracy upon all the results and developments of Logic. Indeed, as Professor De Morgan has said, Mathematics and Logic are the two *exact* sciences. The primary doctrines of chemistry may require alteration as new combinations of the elements are brought to light; the progressive theories of physiology are modified with every advance of microscopical investigation; the glorious revelations of astronomy present an ever-changing aspect; but Logic, like Mathematics, abides, eternal and immutable.

The preceding remarks will probably have pointed out to the reader that Logic is concerned with language as distin-

* For further information as to form and matter see page 39 *et seq.*

guished from the ideas conveyed by the use of words; but in order that the student may be well grounded in the fundamental truths of the science before he proceeds to study its details, I shall add some further observations upon this point.

Language in its ordinary sense, that is, speech, is useful as a means of communication in two ways: it enables us to minutely describe, or, in other words, to analyse, our various ideas, and it also enables us to convey, by a single sound or sign, the combined impression of many particulars. Take, for example, this description:

> "I gazed upon her form
> Transcendent, and upon her face which gleamed
> Pale through her tears, like some fair statue bathed
> In the cold moonlight; and I marked the mute,
> Sad eloquence of that love-charged heart
> Which quickly heaved its alabaster veil
> In trembling fear."

Here gradually dawn upon us the many subjects of attention which exist in a single object, and it is only by means of a protracted analysis such as the above, that we are able to convey a complete idea of it. But then, again, we sometimes wish to express the notion of a numerous class of objects, in such a manner that the impression produced may serve for any one of them. Thus, suppose the objects were men, horses, cows, sheep, lions, &c.: we should merely confine our attention to those points in which they resembled each other, and should bestow a name upon this group of qualities, such as "animal," by the use of which we might attain the desired end. This process is the reverse of the first, but at the same time is in a measure dependent upon it, for in order to ascertain the points of resemblance between various objects, a partial analysis is at all events necessary. Accordingly, Logic takes cognizance of both operations, and investigates the relations which subsist between them and the act of reasoning itself.

It has been said above that language enables us to convey by a single sound or sign, the combined impression of many particulars. Now it is our ability to do this, which alone enables us to conduct a process of reasoning; or otherwise we should find it impossible to judge of the relations between two ideas or objects—a condition which is evidently essential to an argument. One of the most curious proofs of this is afforded by deaf-and-dumb persons, who, when they have once been taught to speak by means of their fingers, are observed to use this means of recording their impressions, even when thinking alone. And it has been asserted, that "it will be found by any one who will question a deaf-mute who has been taught language after having grown up, that no such thing as a train of reasoning had ever passed through his mind before he was taught."*

We have hitherto considered Logic purely as a Science, but it is very frequently regarded as an Art, and perhaps it is this mode of viewing it which holds out the strongest incentive to the student. For it can only be the few who will voluntarily engage in the study of principles which, complete in themselves, give promise of no result beyond that delight which naturally arises from the consideration of organic symmetry and perfection; the great majority being altogether occupied with the hope of turning their knowledge to some useful purpose. Therefore, in the following pages I shall endeavour to give as practical an effect as possible to the various laws of thought which we shall investigate; and the student will thus find that Logic, instead of being merely an "ingenious recreation," is in reality a powerful aid to the prosecution of all other studies. Not that reasoning alone will suffice for the *discovery* of truth, as to do this an extended *observation of facts* is indispensable; but when we have collected a sufficient quantity of facts, we shall find that an

* Whately's "Logic," p. 13.

acquaintance with Logic will greatly assist us in deducing a correct inference.

I now trust that a tolerably clear notion has been gained of the nature and extent of Logic; and in the next place I shall briefly describe the method of proceeding which I intend to adopt in my explanation of the science. First, then, it will be advisable to select some example of pure reasoning, and, having dissected it, to point out the various members of which it is composed, together with the principles which form, as it were, the framework of the structure. We shall thus obtain a bird's-eye view of the country before us, and we shall be able to advance without doubt or hesitation to the end of our journey. Accordingly, it will next become our duty to examine each branch separately and in detail, which being done, we shall proceed to the consideration of the various combinations formed by these branches, and so at length we shall be enabled to construct, or to analyse at pleasure, any train of argument, however extensive it may be. Here, strictly speaking, the study of Logic as such should terminate; but in order that the utility of this treatise may be increased, I shall devote a chapter to the discussion of the several fallacies which are of most frequent occurrence, giving such rules for their treatment as have been found most effectual. The concluding portion of the work will consist of some remarks upon the proper application of Logic, with various illustrative examples.

Such is the course which I propose to take, and if the student be not dismayed by the shadowy anticipation of technical difficulties which have no real existence, he will find an ample reward for all his labours. A systematic regulation of his intellect; a probe wherewith to examine the most mysterious doctrines of philosophy; a wand before whose potent touch the stately fabric of deceit and fraud will disappear;—these are but a few of the benefits to be obtained by a study of Logical science.

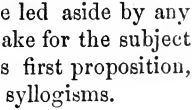
A TREATISE ON LOGIC.

CHAPTER I.

AN INQUIRY INTO THE VARIOUS MEMBERS OF AN ARGUMENT.

It has already been stated that our first step towards a right understanding of Logic must be a strict examination of some definite argument. Now, as we are not all concerned with the *subject* of the reasoning, it will be the best plan for us to choose some example which shall present us with the fewest and most simple ideas, so that we may devote our whole attention to the reasoning *process*, and not be led aside by any extraneous matters. Accordingly, let us take for the subject of our investigation, the proof of Euclid's first proposition, which may be thus stated in arguments or syllogisms.

1. The radii of the same circle are equal to one another,
   A C and A B are radii of the same circle B C D;
   ∴ A C is equal to A B.



2. The radii of the same circle are equal to one another,
   B C and A B are radii of the same circle A C E;
   ∴ B C is equal to A B.
3. Things which are equal to the same thing are equal to one another,
   A C and B C are equal to the same thing (viz. A B);
   ∴ A C is equal to B C.

Taking any one of the above syllogisms, we see that it is composed of three statements, among which this relation subsists; that if we admit the truth of the first two, we cannot

avoid admitting the truth of the last. This last statement is termed the *conclusion*; the other two being called the *premises*. And here the question comes—why is it, that, having admitted the premises, we are compelled to admit the conclusion? To answer this we must examine the constitution of each premiss, and ascertain whatever is implied thereby. Thus, in the first of the syllogisms given above, we find as a commencement, the following assertion or proposition: —"radii of the same circle are equal to one another:" where a certain property, viz., "equality," is asserted, or, in logical language, *predicated*, of a group or class of objects, viz., "radii of the same circle." That is to say, "equality" is a property common to every individual comprehended in the class. The second proposition is to this effect:—"A C and A B are radii of the same circle;" that is, we assert A C and A B to be individuals of that very class, concerning which we admitted that "equality" was common to every one of its members. Consequently we are compelled to admit that A C and A B possess the property of "equality," and this admission forms the conclusion.

Our mode of procedure has therefore been as follows: we first predicate something of a certain class of objects; we then assert that certain individuals belong to that class; and lastly, we predicate the same thing of the individuals which we had predicated of the class.

Now suppose the syllogism had stood thus: "Radii of the same circle are *not* equal to one another; A C and A B are radii of the same circle; therefore A C is not equal to A B:" it would still be perfectly valid, for, having denied that a certain property is enjoyed by a class of objects among which we admit certain individuals to be, we must necessarily deny that those individuals possess the property in question.

We thus arrive at this axiom or law: "Whatever is affirmed or denied altogether of any whole, may in like manner be affirmed or denied of any individual part belonging to, or comprehended in, that whole." Aristotle was the first who distinctly enunciated this great truth, and it is commonly known as "Aristotle's Dictum," or the "*dictum de omni et nullo*."

It may at first seem strange that a statement so simple and obvious should be characterised as a great truth; but a very little reflection will soon convince us that any law which is of universal extent and application, must be the more valuable according as it is the more simple; and therefore it is with justice that Aristotle is honoured for having enabled us to explain the formation and examine the validity of any argument whatever, in so plain and satisfactory a manner. Another fact also which will appear improbable, is that the dictum may be universally applied; that is to say, no syllogism can be valid or admissible unless it strictly complies with the requirements of the dictum, and in a later portion of this work rules will be found by means of which it is possible to bring every specimen of reasoning to this test. Indeed, if we would become thoroughly acquainted with the principles of logical science, we must invariably bear in mind the dependence of every train of thought upon the dictum of Aristotle.

But it is now time that we should revert again to our example of reasoning, and continue the division of each syllogism into its component parts. We have already seen that a syllogism consists of three propositions divided into the two premises and the conclusion; we will now examine the propositions themselves more closely. In the statement "radii of the same circle are equal to one another," we see three distinct portions: first, the subject of which we are speaking, and of which something is predicated (that is, asserted or denied); secondly, the attribute or condition which is predicated of the subject; and thirdly, the sign of affirmation or negation. The technical names for these are, the *subject*, the *predicate*, and the *copula*.

In the proposition above quoted it will be observed that the *whole* of the subject is spoken of; for when we say "radii of the same circle," we evidently mean every radius that could possibly be drawn. Accordingly, such a proposition is termed *universal*, as the predicate is universally applied to every part of the subject. But if we had spoken of a portion only of the subject, and had said "*some* of the radii of the same circle are equal to one another," we should have what is called a *particular* proposition inasmuch as the predicate

is affirmed of some particular *part* of the subject, and not of the *whole*. Thus we see that propositions may be always divided into universal and particular, and this distribution is said to be made according to quantity.

Again, "equality" is predicated affirmatively of "radii of the same circle;" the sentence is therefore termed an *affirmative* proposition: while if the predicate had been denied of the subject, thus, "radii of the same circle are *not* equal to one another," it would have been a *negative* proposition. We have, therefore, another system, by means of which to classify every possible proposition, and this distribution is called a division according to *quality*.

And here we have introduced to our notice a very important branch of Logic, namely, division; by means of which mental process we may at all times obtain a distinct grasp of any subject which occupies our attention. Indeed, this faculty would seem to be an inherent principle of our nature, for whatever may be the science, an attempt has always been made from the commencement, to properly classify and arrange its various subdivisions; the best examples of such a course being found in such studies as Natural History, Comparative Anatomy, &c. Accordingly, as Logic instructs us concerning the principles upon which alone a perfect division can be performed, it is an additional proof of the necessity which exists for an intimate acquaintance with that science.

We have now glanced quickly, but I trust intelligibly, at the structure of a syllogism and its component propositions. It remains that we should consider the nature of the *materials* of which the propositions are formed, having already discussed the mode of framing them together. The subject of the first proposition is, "radii of the same circle;" and in saying this we speak of a class, the individuals of which, though they may differ among themselves in many respects, yet have some features common to all. Thus, one radius of a circle will be unlike its fellows as regards position, but it will be exactly similar with respect to magnitude. So, when speaking of a given circle we mention its "radius," we employ a name that may be applied to any straight line whatever that is

drawn from the centre to the circumference. Such a word is called by logicians, a *common-name* or *common-term*, because, as just stated, it is enjoyed in common by a multitude of objects. But if we proceed to the subject of the second proposition, we are met by terms which differ entirely from the preceding, viz., "A C and A B," the names given to individual radii. These of course can only be applied to a single object, and are consequently known as *singular-terms*, thus serving to distinguish the various members of a common-term.

Let us here pause for a moment to consider the results at which we have now arrived, and let us fully comprehend the purport of common and singular terms. We see that a common-term when applied to an object, merely indicates that it possesses certain properties which are shared in like manner by all the other constituents of a specified group. It is, therefore, evident that such a term or name belongs in reality not to an individual, but to a definite combination of qualities which are found in it. And the mode in which a common-term is obtained, is by comparing a number of separate objects, observing the points wherein they agree, combining these points of agreement into one idea, and then giving this combination a name, so that at any future time we may be able to recall the idea without having the trouble to go through the same operations again. Thus, for example, men observed the properties of many natural bodies, and finding that a certain number refused more or less to alter their volume or shape, the name of solidity was conferred upon this property; and, accordingly, whenever we hear the term "solid" applied to anything, we at once know that the body spoken of will resist a change either as to volume or shape. This process of combining various properties into one idea is called *abstraction*, and is the reverse of that previously described, namely *division;* for while the latter is al ogether occupied in discovering the points of difference between various notions, the former exclusively deals with the points of resemblance.

A singular-term is on the contrary employed to designate individuals instead of classes, and therefore is a mere arbi-

trary sign which conveys the notion of one single object. Such are all names of persons, rivers, cities, &c., and even common-terms may be converted into singular-terms by the employment of the demonstrative pronouns, as "this book," "that house," &c. &c.

There is yet another distinction of the members of a proposition, which it will be needful to notice. We have hitherto spoken of the subject and predicate together with the copula; now the two former are called the *terms*, as when a proposition is expressed in logical order they will form its respective boundaries or *terminations*, the copula occupying an intermediate position.

Of these terms it will be observed that there are three in each syllogism; two forming the subject and predicate of the conclusion, while the other is confined to the premises, in both of which it occurs. From these positions it is, that the names of the respective terms are derived; thus, the predicate of the conclusion is called the *major-term*, the subject of the conclusion is known as the *minor-term*, and the remaining term is characterised as being the *middle-term*. These names, too, are used to distinguish the premises, for that proposition which contains the major-term is called the major premiss, while the other, for a similar reason, is styled the minor premiss.

We are now in a condition to perceive clearly the full force of the train of reasoning which we chose in the first place as the subject of our analysis. In the first syllogism, we see that a middle-term, "radii of the same circle," is chosen, with which are respectively compared the major-term, "mutual equality," and the minor term, "A C and A B;" the result of this comparison being, that a certain relation, viz., "mutual equality," may be predicated of A C and A B. In the second syllogism, we have precisely the same major and middle terms, but a different minor-term, which, however, is found to bear a similar relation towards "mutual equality," as did the other minor, "A C and A B." The object then sought to be attained, is to show the equality of certain portions of the two minor-terms, and this is done by employing a fresh middle-term to serve as a means of connecting the idea of "equality"

with the notion "A C and B C." This middle-term is "things which are equal to the same thing," and when it has been properly applied, as in the third syllogism, we attain the desired result, viz., "A C and B C are equal to one another," or "A C is equal to B C."

Finally, let us recapitulate the information which we have acquired from our rapid survey of the extent of Logic. We find that it will be necessary to investigate, first the subject of notions or terms; next, the comparison of terms, or propositions; and finally, the deducing a conclusion from the juxtaposition of two propositions, or in other words, the nature and construction of syllogisms.

Necessarily this preliminary chapter has been somewhat discursive, and has but briefly sketched the more salient principles and branches of Logic. This glimpse of the path before him, however, as stated in the Introduction, will probably prove of great assistance to the student, for he will now proceed to a more detailed examination of the science, with a good notion of what he may expect to meet; a course which is surely preferable to that too often followed, whereby the learner is introduced at once to tedious technicalities, without the slightest idea as to where he will find himself at the end of his study.

CHAPTER II.

OF NOTIONS OR TERMS.

THE student is now about to descend into the plain, and to enter upon that road whose various windings and ultimate end he has recently surveyed from an eminence. Consequently he will for awhile lose sight of the goal, but as he is in a great measure acquainted with the general features of his course, he will not be dismayed if the path should not immediately appear to tend in the desired direction. And here I may mention that at first we shall proceed through a region abounding in hard names; but as the principal technicalities of the science have been already introduced, together with the principles upon which they are based, no difficulty will, I apprehend, be experienced in conquering what might otherwise prove a rather formidable array.

Our immediate subject is, of course, *notions* or *terms;* for we must obviously possess a certain number of ideas (logically, *terms*), before it would be possible for us to make any attempt whatever at a train of thought or reasoning. Accordingly, it might be considered necessary that I should in the first place examine the question as to whether ideas are coeval with the mind itself, or whether they are the results of experience: but, were I to do this, I should quit the domains of Logic for those of metaphysics. Suffice it, therefore, if I describe the manner in which we obtain *certainly many* of our ideas, and *possibly all.*

§ 1. *Simple-apprehension.*

When any object is presented to the mind; and the attention is directed to it, a certain mental impression is produced, unintelligible indeed as to its nature, but the result of which

is that the object is recognised when again observed. That is to say, an *idea* is formed in the mind of that combination of properties and appearances which revealed itself to the senses upon inspection. Such an idea is termed an *intuition*, or *singular-representation*, and evidently can only refer to an individual object. It is also necessary for purposes of intercommunication, that names should be given to these several intuitions, and these names are called *singular-terms;* such, for example, are, "London, France, Charles, Bucephalus."

Now it is evident that if a separate personal name were to be bestowed upon each object, great confusion would result; and as in the majority of cases it is by no means essential that, when speaking of an object, reference should be made to some particular individual, it would speedily be found necessary to assign certain *class-names*, under which a number of similar objects might be grouped. This, accordingly, is done in the following manner.

Suppose a great many individual books had come under our notice, and we wished to be able to recall at pleasure the general idea produced by any one of them, without, however, mentioning it by name. In the first place we should compare several together, and ascertain the points in which they resembled, and differed from each other; thus, we should perceive that some were illustrated and others not; that one related to biography, another to history, and a third to mathematics; that there were many gradations of size and bulk; that they were bound in various styles; but also that every one of them agreed in possessing certain definite properties. These properties we should then proceed to abstract or separate from those qualities wherein the volumes differed; and, combining the former into one idea, we should be able to conceive of a class of things, each member of which would contain in itself all those *marks* or *attributes* which we had selected as essential to the idea in question. Finally, we should apply some name, in the present case "book," to the class thus imagined, and in this manner we should accomplish the object with which we had set out.

The process which has here been described is that of abstraction; it will be seen to consist of five steps, viz., com-

parison, or placing several objects together in order to judge of their resemblance; reflection, by which we decide upon the properties in which they agree or differ; abstraction, which enables us to form the points of resemblance into one idea complete in itself; generalisation, or the conception of a class whose members shall each contain (*inter alia*) this compound idea; and denomination, by means of which we impose a name for the purpose of recalling to our remembrance both the class and the idea; the names thus imposed, being known as *common terms; e.g.*, "sea, river, mountain."

Into these two classes, then, viz., singular and common representations, may all our notions be divided; and as that action of the mind which merely consists of forming an idea is termed simple-apprehension, so it is said to be *incomplex*-apprehension when we receive a notion of individuals without observing any relation between them, or *complex*-apprehension, when we perceive the existence of a class.

§ 2. *Abstraction of Common-notions*

The faculty of abstraction is possibly the most active and powerful with which the human mind is endowed; far from remaining quiescent when it has succeeded in forming a common-notion (or *conception* as distinguished from *intuition*) by the comparison of separate individuals, it instantly proceeds to repeat the process on a larger scale. This is done by treating a number of *classes* as so many individuals, and then—when their points of resemblance have been noted and combined into one idea—forming a higher class, which will include amongst its members all the former classes. Nor need we stop even here, for it is evident that no limit exists to the number of repetitions of such a proceeding, unless indeed there be a limit to the exercise of imagination itself.

Now every science arranges the subjects upon which it treats, in a perfectly similar manner, this being based upon the results of abstraction: accordingly, logicians have devised a certain scheme of names for this system, which we shall now explain.

A single object is called an *individual,* and comprehends within itself two distinct sets of marks or attributes; these are; first, that combination of qualities which we abstracted to form the idea of a class, and, secondly, such attributes as remain. Each of the former is termed a *property,* whilst the latter are called *accidents* or *differences;* the class of which the individual is a member being known as a *species.* This species, which is merely composed of individuals, is called the *lowest* or *infima species,* and the next higher class, being founded upon a consideration of infimæ species, is termed a *genus:* the latter name, however, is only applied when we contrast the higher class with the lower, for in the next stage of our conceptions we come to a yet wider genus, of which the previous genus is only a species. Thus we go on until we arrive at the most comprehensive class of all, which is accordingly named the *highest* or *summum genus,* and this, of course, can never be a species, for there is no higher class to include it. Every other genus is called a *subaltern genus,* being alternately a species and a genus.

An example of the above method of arrangement may be given as follows:—

Individual	Iron.
Infima species . . .	Metal.
Subaltern genus . .	Elementary substance.
Summum genus . .	Matter.

Accordingly, we can say that iron is a kind of metal; that a metal is a species of elementary substance; that an elementary substance is a genus of which metals are a species, or that an elementary substance is a species of matter.

It is, of course, quite clear that the precise details of the system, such as the question of what are to be considered as individuals, or where abstraction is to cease, must be left to the arbitrary regulations of each science: the only point here insisted upon being the fact that this system is employed in every pursuit which engages the human mind, thus showing decisively that thought proceeds according to certain fixed laws; which laws it is the province of Logic to explain.

§ 3. *Predicables, Extension, and Intension.*

We have already stated that "predication" is the affirming or denying one thing of another; thus, when I say "A is B," I am said to predicate B affirmatively of A, but were I to state that "A is not B," I should predicate B negatively of A. Now those notions or terms which may be predicated affirmatively of others are called "*predicables*," and must necessarily include a greater number of objects than the subjects of which they are predicated.* Thus, a species may always be predicated of an individual, or a genus of a species; and therefore, in accordance with the above-given example, we may say "iron is a metal," or "metals are elementary substances," but not "metals are iron," or "elementary substances are metals."

It will here be seen that in legitimate propositions, the subject contains within itself not only the whole of the marks or attributes which collectively form the predicate, but also an additional series of qualities. For instance, "iron" contains the common-notion of a "metal," together with those peculiar marks which enable us to distinguish it from other metals: accordingly, there is a greater number of marks or attributes in the subject than in the predicate, and this kind of comprehensiveness is called the *intension* of a term. But, on the other hand, we see that the predicate embraces a much larger number of objects than the subject, as a "metal" not only includes everything that is "iron," but multitudes of other things besides, such as "gold, silver," &c.; and this species of capacity is known as the *extension* of a term. Consequently, a term used in extension comprises only the specific properties of a body; and as it is, therefore, more general and less distinctive, it may always be predicated of a term used in intension, which consists both of properties and of accidents.†

§ 4. *Division of a Common-notion.*

If we are desirous of completely understanding any subject, it is very necessary for us to examine it closely, and the

* Here, of course, I allude to common-terms, for a singular-term can never be predicated of anything but itself; *e.g.*, we can say "John is John," but not "a man (*i.e.*, every man) is John."

† See page 17.

mental process by which we perform this is what I shall now consider. It is, in logical language, termed *division*, and consists in viewing every general idea as composed of two main sections, viz., the several members or parts of the idea, and the tie which connects them together. We then place the various parts in regular symmetrical order, such as is best adapted to their mode of union, and thus we are enabled to study each object separately, both as regards its own individual features, and its relations to the other members of the system.

Now the "tie" or "mode of union" which has been here alluded to, is altogether arbitrary, and depends upon the purpose which we have in view when entering upon the study of any subject. Take, for example, the science of natural history: Aristotle, looking upon the blood as the grand basis of the phenomena of life, divided all animals into two great classes, one possessing colourless and the other red blood, which done, he proceeded to describe the individuals forming these classes; Cuvier, on the contrary, adopted the bony skeleton as his guide in the arrangement of the various forms of life; while Rymer Jones, Vogt, and Siebold have respectively chosen the nervous system, the phenomena of development, and the relative complexity of organisation, as keys wherewith to unlock the vast storehouse of nature.

But when we have in this manner set apart some portion of the subject as a general principle to which we must constantly adhere, it becomes necessary to separate the subject into as many parts as may be convenient. This is done by observing the marks in which one group or class of objects differs from another, and thus dividing the whole of the subject into a certain number of genera: each of these genera is then examined and similarly divided into lower genera; and so we go on until we can no longer discover any smaller groups in a class, but are compelled to enumerate the individuals of which it consists. Thus we arrive at a regular system of summum genus, subaltern genera, infima species, and individuals.

In order, however, that this process may be properly performed, logicians have laid down the following rules:—

1. The *whole* subject must be divided: that is to say, the various parts taken together must exactly equal the genus divided.
2. The division must be conducted according to some single, definite principle.
3. The parts must be quite distinct; no two containing any common object.

Thus, if we were studying architecture, and wished to obtain a correct idea of the class of objects which are termed buildings, we must discuss the whole of the subject, and not confine our attention to a few species, such as palaces and temples only. And then when commencing the division, we must proceed according to some settled principle, such as, for instance, "application," consistently with which we should form the different species of "private-dwelling-houses," "factories," "warehouses," "churches," &c., and therefore no confusion would result, for the third rule given above would remain uninfringed. But if we were to pursue a different plan, and to divide buildings indiscriminately into "palaces," "Doric," "Gothic," "prisons," &c., we should violate both of the latter rules, having employed two principles of division, viz., "style" and "application," in consequence of which the various classes would be intermingled, and no true division would be performed; for it is evident that some palaces might be Doric and others Gothic, &c. This error is termed *cross-division*, and is one of the most frequent sources of confusion and perplexity in discussion and argument.

§ 5. *Positive, Negative, and Privative Terms.*

In order to test a division as to whether it be perfect, logicians are accustomed to take each part separately, and examine the possibility of dividing the whole subject into *positive* and *privative* portions with reference to the selected part. Thus, suppose the subject "man" be divided according to the principle of "colour:" we should have the four species of "white-men," "black-men," "red-men," and "yellow-men." We then see that it is possible to also divide "man" into the two ideas or conceptions of "whitemen" and "non-whitemen," for black, red, and yellow may all be described as non-white.

In the same manner "man" may be divided into "black" and "non-black," "red" and "non-red," "yellow" and "non-yellow," and so at length we see that none of the classes intermingle with each other.

The term "white-men" is called *positive*, because it denotes that a certain view (white) is taken of the object (men), while the term "non-whitemen" is said to be *privative*, in consequence of its implying that such a view might be, and yet is not taken. If, on the other hand, it were impossible to form a certain notion of a subject, the term which implies this, such as, for instance, a "non-white negro," would be styled *negative*.

§ 6. *Definition.*

In the process of logical division it is evidently necessary that we should employ some means of precisely determining, first, the full extent of the subject to be divided, and then the respective capacities of the various parts or species: this we are enabled to do by the use of *definitions*, that is, certain expressions which describe an object or notion in such a manner that we are enabled to distinguish it from all others.

Now the act of forming these expressions is termed the process of definition, and consists in an enumeration of the various attributes composing a notion. As a notion, however, may be either singular or common, we are obliged to use two kinds of definition, one of which, *accidental-definition*, is applied to individuals, and consists of the specific name together with the accidents; while the other, *essential-definition*, being applied to classes, consists of the generic name, together with the specific difference. Thus, the Thames might be defined as "a river which flows through London," where "a river" is the name of the species, and "flowing through London" the accident which distinguishes the Thames from other rivers. Again, we may define light as "a species of motion affecting the optic nerves in such and such a manner," the genus being "motion," and "affecting the optic nerves" the difference which distinguishes light from other species of motion.

This latter kind of definition, consisting of the genus and

specific difference, is also termed *logical-definition*, in opposition to *physical-definition*, which enumerates such parts of the object as are *actually* separable: *e.g.*, the boiler, mechanism, &c., of a steam-engine. Some writers also include physical-definitions under the head of essential-definitions.

Various rules have from time to time been given by logicians for the purpose of securing correct definitions, and may be summed up as follows.

1. The definition must be of exactly the same extent as the object defined: that is to say, it must not be of too narrow or too wide an application. Thus, to define "gravity" as "a force which attracts bodies to the earth" would be too narrow, as not including the celestial attractions, and being only applicable to *terrestrial* gravity: to define it as "a force which attracts one body to another," would be too wide, in consequence of its including magnetic attraction, &c.

2. The definition must not contain anything beyond what is absolutely essential to the subject. For instance, it would be incorrect to say that a "man" is "an animal endowed with the faculty of speech *and with life*," as it might then be supposed that the existence of an animal with speech, but lifeless, was possible.

3. The definition must be plainer than its subject, and must not be a repetition of the same term: *e.g.*, the explanation that "a metal" is "a metallic substance," would be no definition at all, while to assert that it is "a product of Plutonic action" is equally unsatisfactory.

§ 7. *Names and their Divisions.*

We have already seen that when an idea or conception is gained of any object or class of objects, some name is immediately attached to it, for the purpose of recalling the impression at any future time. It now remains to describe the various species into which these names are divided for logical purposes.

1. Making a division according to logical quality, we find that all names or terms may be divided into *positive*, *privative*, and *negative*, which have been described above. Positive terms, however, are also called *definite*, from their distinctly

defining an object; while for the reverse reason privative and negative terms are styled *indefinite*.

2. Names, as regards the method of using them, are either *univocal*, *equivocal*, or *analogous*; that is to say, some have only one meaning, such as "book," "sofa;" others have several meanings, such as "light," which signifies either the contrary of "heavy," or a physical force; while others, again, are extended from one object to another in consequence of some similarity—thus, "tongue" may be applied either to the body or to a piece of land.

3. Viewed as to their mutual dependence, terms are *absolute* or *relative*. The former appellation is bestowed upon those terms which are considered by themselves as a whole; the latter belongs to those which form part of a more complex idea. For example, the term "man" would be absolute; while *plaintiff* would be relative, as being a portion only of the idea plaintiff-and-defendant. It will therefore be seen that relative terms exist in pairs, and cannot be applied to the same object, as then they would be what is called *opposite*, to distinguish them from *compatible* terms, as those are named which may be so applied.

Correlatives is a name given to each pair of relative terms, and implies their mutual connection.

4. Terms are either *concrete* or *abstract*, according as they imply a notion together with the object furnishing the notion, or the notion by itself. Thus "fluid" is a concrete, "fluidity" an abstract term.

Also when the terms employed are common terms, or the names of classes, a further distinction will be observed. Take, for example, the concrete term "fluid;" it is evident that there is here implied a substance possessing certain attributes; accordingly, such a term is called *attributive*, or *connotative*, because it *connotes* some attributes together with the object. Again, the abstract term "fluidity" is, in like manner, named *absolute*, or *non-connotative*, from its merely denoting an attribute and nothing beyond.

§ 8. *Opposition of Terms.*

There is said to be a *contradiction in terms*, or two terms

are said to be in *contradictory opposition* to one another, when the only difference between them consists in the respective presence and absence of a negative particle; this difference enabling us to apply them universally. Thus, everything must be either "living" or "not living," "red" or "not red," &c.

When, however, two terms differing as to the same idea cannot be both applied to the same object, and yet there are some objects to which neither can be applied, such terms are said to be in *contrary opposition* to one another: *e.g.*, a man is not at the same time "walking" and "running," but a tree does neither.

§ 9. *Structure of Terms.*

An idea or term is expressed by a word or words; thus, "man," "horse," "steam-engine," "the Emperor of Russia," and such words as can be used *alone* to represent a term, are called *categorematic;* while all others are denominated *syncategorematic.* Sometimes, however, we meet with a single word apparently filling the place of a term, but for which it is necessary to substitute some other expression before its full import is conveyed. Take, for example, the sentence "He loves;" this, if reduced to logical form, would be "He is a person who loves."

§ 10. *Conclusion and Recapitulation.*

We have now reached the end of our investigation into the first great division of Logic, and before we proceed any further, it will be well for us to cast a brief glance backwards, and fully comprehend the connection which exists between the subjects just discussed, and those to come.

The course, then, of our investigations has been first to analyse the method in which we gain and record the impressions or ideas produced by the various objects which attract our attention: in doing this we found that all our ideas are either of individuals or of classes, the former being the result of incomplex-apprehension, the latter of complex-apprehension, which consists of the five processes of comparison, reflection, abstraction, generalisation, and deno-

mination. In the next place we examined the mode of arranging and classifying our ideas by the abstraction and division of conceptions (common-notions): this led us to perceive that the subject of a proposition embraces more marks or attributes than the predicate, while the predicate comprehends a greater number of objects; that is to say, the subject has the greater intension, the predicate the greater extension. We then showed how a logical division might be tested by the use of positive and privative terms, which done, it became our duty to describe the process of definition, and to explain the various rules which have been laid down for the purpose of securing correct results. Finally, we enumerated the divisions of the various names which have been bestowed upon ideas, and concluded by noticing the opposition and structure of terms.

It will of course be understood that in order to form an idea, it is not necessary that a tangible, corporeal object should be presented to the senses, for we have many notions to which there exists no corresponding reality: such, for example, are our ideas of justice, honesty, &c. In fact it may be said that no common-notion whatever has any existence out of our own minds; the conception of "man" for instance being merely that of a combination of marks or attributes which are never found separately by themselves, but are always united to other objects. Thus it is certainly true that the idea "*man*" has no *isolated* existence, but still it cannot be denied to *exist*, simply because it does so in conjunction with something else.

This question, here touched upon, is the celebrated bone of contention between the schools of the nominalists and the realists, the former following Abelard, and denying that common-notions (or universals) are anything more than mere names, while the latter, under the guidance of Plato, strongly affirmed the reality of their existence. The days of the schoolmen was the time when this controversy grew most warm, and such was the importance attached to the subject, that kings and popes did not scruple to exert their utmost power in the attempt to secure the triumph of the sect which they respectively patronised. But this by the way.

Now when the mind has once become supplied with ideas, it is enabled to reflect, the result of which is the formation of certain judgments. These judgments, when formally stated, are termed in logical language *propositions;* and, accordingly, the subject of our next chapter will be an examination of their origin and nature.

CHAPTER III.

OF JUDGMENTS OR PROPOSITIONS.

§ 1. *Formation of Judgments.*

Judgment is the act of determining by comparison whether one idea is or is not included within another; that is to say, it ascertains whether an individual belongs to a certain species, or a species to some genus. Archbishop Thomson has defined it as "an attempt to reduce to unity two cognitions." He says, "When one decides that 'Socrates is wise,' it is that hereafter one may, by combining the two notions, think of 'the wise Socrates.'" Now it is by no means evident that the two cognitions are here attempted to be reduced to *unity*, for no person would surely expect to render them so inseparable, that whenever the idea of "wisdom" presented itself to his mind it should be invariably accompanied by the notion of "Socrates." In fact the judgment that "Socrates is wise," is merely an assertion that "Socrates belongs to the class or species of wise men," or "Socrates possesses wisdom," thus enabling us to fix his place more exactly in our system of ideas.*

Accordingly, it will be seen that judgment is the result of that mental faculty which so strongly impels us to classify and arrange the various notions with which our senses provide us, so that we may the more clearly comprehend the various dependencies and relations by which they are connected together into one harmonious whole. We have already considered three portions of this faculty, viz., abstraction, division, and definition; it now remains to consider judgment, without which none of these processes could be conducted.

* For further information upon this point, see Appendix A.

And here it might well be asked whether, if the formation of common-notions is the result of judgment, a judgment also in its turn is not the result of reasoning—for we have already seen that the conclusion of a syllogism is a judgment or proposition. This question, however, belonging as it does to metaphysics, cannot be satisfactorily answered in the present place; and, therefore, I shall at once proceed to discuss the nature and *proximate* origin of propositions, without minutely investigating their remote ancestry.

§ 2. *Categorical Propositions.*

A categorical judgment or proposition is an assertion that one idea agrees or disagrees with another, and consists of three parts—the *subject* or idea under examination; the *predicate*, or idea to which the subject is referred; and the *copula*, which determines the relation between them. Thus, in the proposition "lions are animals," the subject is "lions," and is connected to the predicate "animals," by the copula "are," which implies that "lions" form a species of the genus "animal." This judgment results from our having compared the two ideas with a view to ascertain whether the attributes of "animal" were contained in "lion."

The subject and predicate of a proposition, may of course be infinitely varied, since there is no limit to the number of ideas; but the copula always remains the same, being either "is," or "is not," or their equivalents. And here it may be remarked that the word "is" signifies, when employed in a proposition, the *identicality* of the subject and predicate, such *identicality* being, however, *limited* by the form of the proposition. The subject and predicate are also called the terms of the proposition, as they form its boundaries or terminations.

Categorical propositions are divided into *pure* and *modal*—the former being cases where the subject is *directly* asserted to agree or disagree with the predicate; the latter where the subject is said to agree or disagree with the predicate *in some particular manner*. For instance, "The sea is rough;" "He addressed the people;" are both pure, but "The sea is terribly rough;" "He addressed the people good humouredly;" are modal. This distinction is, however, of no use for logical pur-

poses, since we may always treat modal propositions as being pure, by simply attaching the *mode* to either the subject or the predicate: thus, in the example above given, "terribly rough" must be taken for the predicate.

§ 3. *Hypothetical or Conditional Propositions.*

All judgments are not formed by a comparison of existing notions, for it is possible to decide upon the mutual relation of two assumed conditions of things. Accordingly, we meet with a class of propositions termed *hypothetical*, or *conditional*, whose assertions are subject to a certain *condition:* of this kind are such sentences as the following—"If the results of geological science are trustworthy, the earth has existed for countless ages." "If you do this well, you shall be rewarded."

Hypothetical propositions are not, however, to be considered as different in nature from categoricals, for both species of judgment result from precisely the same operation of the mind. This will be clearly seen if we examine one of the instances given above, and ascertain what it is that we really assert. Taking the first example, it is evident that we decide nothing as to the results of geological science, or as to the earth, but we say that the assuming those results to be trustworthy would necessitate our granting the earth to be of the age stated. This judgment, then, may be expressed as follows, viz., "The case or supposition of the results of geological science being trustworthy, is a case or supposition of the earth having existed for countless ages"—where the subject, copula, and predicate of a categorical proposition will be at once recognised.

§ 4. *Disjunctive or Alternative Propositions.*

There is yet another form which our judgments may assume, this being the statement of some alternative, such as, "Either Tyndall is wrong, or mechanical force produces heat;"—which, accordingly, is known as a *disjunctive* or *alternative* proposition. To show its harmony with the forms already discussed, we have only to remark that it may be converted at will into a hypothetical, as, "If Tyndall is not

wrong, mechanical force produces heat;"—or into a categorical, thus: "The case of Tyndall being wrong, and the case of mechanical force producing heat, are all the cases possible."

As regards hypotheticals and disjunctives considered apart from categoricals, we shall have more to say when we come to discuss the treatment of arguments where they occur; at present, however, we are concerned altogether with pure categoricals, having shown that all propositions whatever may be regarded as such.

§ 5. *Quantity of Propositions.*

As we have no ideas beyond those of individuals and of classes, our judgments must always be concerning intuitions (singular-notions), or conceptions (common-notions). Now a singular-notion being indivisible, we must invariably treat of the whole of it; but as regards common-notions, we are able to discuss either a part or the whole. This distinction has enabled logicians to divide all propositions according to *quantity;* that is to say, according to the extent of their subjects: and, therefore, whenever the subject is a singular-notion, as, "John is rich,"—or the whole of a common-notion, as, "*All* metals are conductors of heat,"—the proposition is called *universal;* but if only part of a common-notion be employed for a subject, as, "*Some* metals are lighter than water," then it is termed *particular.*

§ 6. *Quality of Propositions.*

Another division of propositions is according to the signification of the copula, which is termed the *quality* of a judgment, and as this must be either affirmation or negation ("is" or "is not"), so propositions are styled *affirmative* or *negative,* according as they respectively express the agreement or disagreement of subject and predicate. Thus, "The whale is a mammifer" is an affirmative proposition; while "No alloy of ammonium is stable" is negative.

It must here be remarked that a negative sign may occur in a proposition, and yet not belong to the copula; in such a case the proposition is affirmative. Take, for example, this

judgment, "Not to accept the offer is great folly," and we see that the "non-acceptance" and "great folly" are declared to agree with each other.

§ 7. *Distribution of Terms.*

Whenever in a judgment a term is used in its full sense—that is to say, as comprehending every single object that it could possibly include—it is said to be *distributed:* accordingly, every universal proposition distributes its subject, but particulars do not. When, however, we examine into the distribution or non-distribution of the predicate, we find that this depends not on the quantity, but upon the *quality* of the proposition. Thus in negative judgments it will be seen that the *whole* of the predicate is declared to disagree with the subject; as, for instance, in the following proposition, "No negro kingdom is civilised," where the entire idea of "civilisation" is pronounced to be incompatible with the idea of "negro kingdoms." But in affirmative judgments the case is different, as we can only infer from the form of the expression, that a *part* of the predicate is implied. Thus, knowing that one *portion* of the genus "animal" is composed of "horses," or in other words, that the attributes forming the idea of "animal" is to be found in every horse, we can say correctly that "horses are animals." Here, then, the predicate is not distributed.

Consequently, we arrive at these two rules:—

1. The subject is distributed in universal, but not in particular propositions.
2. The predicate is distributed in negative, but not in affirmative propositions.

The latter rule is, however, subject to three exceptions; first, when in an affirmative proposition the predicate is a singular notion and is consequently distributed, for we cannot think of a part only of an *intuition;* secondly, when some expression is employed which indicates that the *whole* of the common-notion forming the predicate is compared with the subject. Thus, in both of the propositions, "Davy was the discoverer of potassium," and "These fragments are all that

remain,"—the predicate is distributed. The third exception is to be found in negative propositions, where the predicate is qualified in such a manner as to indicate that *part* only of its signification is employed. This will be observed in such sentences as "Steam-engines are not *some* machines;" "No men are *some* created beings;"—which import respectively that some machines are not steam-engines, and that some created beings are not men. These latter propositions are termed *partial-negatives*, those to which the rule applies being styled *total-negatives*.

§ 8. *Relation of Terms.*

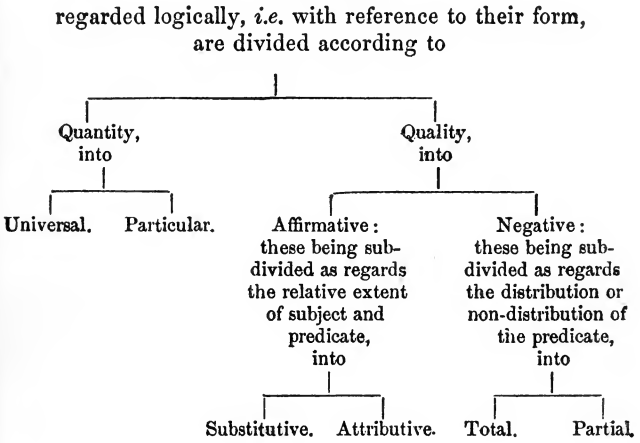
We have already stated that judgment is the act of determining by comparison, whether one idea is or is not included within another. In doing this we find some cases where the notions are of equal extent, such as the various intuitions produced by the same object under different circumstances, or those conceptions which comprise the same individuals. This fact we express in the *form* of the proposition, which consequently indicates that it is the result as it were of *two* judgments, the one having ascertained that the subject of thought belonged to a certain class, while the other determined that it was co-extensive with the class. Such propositions are those mentioned above as constituting exceptions to the rule which declares that no affirmative proposition distributes the predicate.

Now in consequence of this relation, it follows that we may indifferently affirm the predicate of the subject, or the subject of the predicate. Thus it matters not whether we say "Davy was the discoverer of potassium," or "The discoverer of potassium was Davy;" or again, whether we say, "These fragments are all (the fragments) that remain," or "All the fragments that remain are these (fragments)." Accordingly, such propositions are termed *substitutive*, from our being able to employ subject and predicate as substitutes for each other.

All other affirmative propositions have their predicates non-distributed, and merely import that these may be attributed to, and not substituted for, the subjects. On this account they are styled *attributive*.

§ 9. *Systematic Classification of Propositions.*

Having now given a full description of the various divisions and subdivisions of propositions, it will be well to give a short summary of the system. This is best done by the use of a "scheme," as follows:—



Propositions
regarded logically, *i.e.* with reference to their form, are divided according to
Quantity, into
Quality, into
Universal.
Particular.
Affirmative: these being subdivided as regards the relative extent of subject and predicate, into
Negative: these being subdivided as regards the distribution or non-distribution of the predicate, into
Substitutive.
Attributive.
Total.
Partial.

§ 10. *Table of Possible Propositions.*

We see by the above scheme, that propositions are of four great classes, affirmative-substitutive, affirmative-attributive, total-negative, and partial-negative. Each of these may be again subdivided into universal and particular, so that altogether there are eight possible kinds of judgment or predication. The names of these propositions, however, being too long and cumbersome for constant repetition, logicians have adopted certain letters to serve as symbols for these names, and in the following table will be found a list of all possible propositions, together with their respective symbols, and illustrative judgments; the subject and predicate in each being represented by the letters X and Y.

Name.	Example.	Symbol.
Univ. Affirm. Substi.	All X is all Y.	U.
Univ. Affirm. Attrib.	All X is some Y.	A.
Univ. Total Neg.	No X is Y.	E.
Univ. Partial Neg.	No X is some Y.	η.
Part. Affirm. Substi.	Some X is all Y.	Y.
Part. Affirm. Attrib.	Some X is some Y.	I.
Part. Total Neg.	Some X is no Y.	O.
Part. Partial Neg.	Some X is not some Y.	ω.

In this table there are two propositions which, as being of little practical importance, we may leave out of our future consideration. I allude to those whose symbols are η and ω; the reason of their inutility being as follows. When we say "no men are some animals" (η), we mean "some animals are not men" (O), which latter, being a much more forcible and convenient mode of expression, is usually adopted. Also when we say "some men are not some animals" (ω), the power of negation is still less, for there is nothing to prevent us saying at the same time "some men *are* some animals."

Accordingly, I shall confine my future remarks to the six kinds of judgment, U, A, E, Y, I, and O, and when the student is able to treat arguments involving these, he will find very little difficulty in disposing of those rare cases in which η and ω may occur.

§ 11. *Interpretation of the Copula.*

The copula, as already stated (§ 2), signifies a certain identicality of the subject and predicate. This identicality, however, may be considered from several points of view, according to the purpose we have in hand. Thus, if we were engaged in determining the intension of the notion "fluids," *i.e.* in ascertaining what were its marks or attributes, and we were to form this judgment, "All fluids are compressible," we should mean that fluids were contained in the class of compressible substances, *in virtue of one of their attributes being compressibility*. But if we were chiefly desirous to fix the relative extent of the terms, *i.e.* to determine their extension, we should only care to imply by the above expression that *the class of compressible substances included amongst other things the class of fluids.*

It will, however, be observed that these are not two *different meanings* of the proposition, but merely *two different modes of regarding the same meaning.*

Another method of interpreting the copula, or connection between subject and predicate, has been suggested. This consists in viewing the judgment as regards its *denomination*, *i.e.* in considering it as implying that the predicate may be given as a name to each of the objects contained in the subject. The example stated above, if interpreted in this manner, would be held to imply that the name "compressible" might be given to every fluid.

§ 12. *On some other Properties of Judgments.*

It is impossible for us to form a *complete* idea of any object, as we are unable ever to ascertain the whole of its various marks or attributes. Accordingly, we observe continually some new feature, and this it is which causes us to make so many fresh judgments. At the same time there always exists a certain set of marks which are almost inseparably connected in our minds with respective ideas; so that it is scarcely possible to recall these ideas without at the same time recalling those attributes. Take, for example, the case of material bodies; we cannot think of any, without also thinking of shape and extension, two properties of matter.

Upon these considerations, metaphysicians, and after them, logicians, are occasionally accustomed to consider judgments with reference to their bearing upon our knowledge of the subject. If they increase our information, such as those which result from our discovery of some new attribute, they are termed *ampliative.* If they add nothing to what we really know, they are called *explicative* when they are in a measure explanatory of the subject by predicating some closely-connected attribute; or *tautologous*, when the predicate is identical with the subject, such as, "A man's a man."

§ 13. *Concluding Remarks.*

In the present chapter we have taken the subject of "judgments," for logical investigation, and the result of our studies may be summarised as follows.

Judgment is the act of determining the agreement or disagreement of two notions, and when its result is expressed in words, it forms a sentence which is termed a proposition. Propositions may be stated categorically, such as "A is B," or "A is probably B," the former being *pure*, the latter *modal*: hypothetically, such as "if A is B, C is D:" or disjunctively, such as "either A is B, or C is D." All propositions may, however, be reduced at pleasure to a pure categorical form. Accordingly, in a systematic account of judgments, reference is made exclusively to pure categoricals, concerning which there are four great doctrines. The first is of quantity, and divides all propositions into universal or particular, according to the respective extent of their subjects. The second is of quality, and divides all propositions into affirmative or negative, according to the import of their copulæ. The third is of distribution, and determines in what cases the various terms are employed as wholes or parts, *i.e.*, whether they are distributed or non-distributed. The fourth is of relation, and arranges all propositions according to the extent of their predicates; affirmatives being divided into substitutives and attributives, and negatives into total and partial. From this classification it results that there are eight different kinds of propositions, each being for the convenience of logicians distinguished by an arbitrary symbol. Two, however, of these species may be dispensed with as being of little practical importance; and, therefore, only the remaining six need be dwelt upon in future. Judgments may also be viewed as regards the significance of their import, which varies with the method of interpretation. Thus, they may be considered with reference to their intension, or attributes of the subject; extension or relative capacity of the predicate; denomination, or applying the predicate as a name to each member of the subject; or, finally, with reference to their bearing upon our knowledge, according to which they are ampliative, or informing; explicative, or explanatory; tautologous, or useless.

We are, therefore, now in a position to enter upon the investigation of a most important and interesting topic—the formation of new judgments from a consideration of some

already existent. This process, termed reasoning, is as it were, the very climax of logical science, and illustrates the use of our preceding reflections upon terms and judgments. Its study is, however, far from being difficult when orderly arranged, and is calculated to induce the most pleasing emotions in the mind of any person who has attentively pursued it, and has observed the singular simplicity and harmony with which the mind works. In fact, we have already had some remarkable instances of this, for we have discovered that the vast, nay infinite world of ideas—than which nothing can be more varied and diverse—may be referred to a few simple processes of the intellect, and may be grouped together into a system of surprising lucidity. The same thing occurs with our innumerable judgments, which, though outwardly dissimilar and confused, are found to be all constructed on the same plan, and to be capable of arrangement in orderly sequence and regularity.

Accordingly, to him who zealously strives after a complete understanding of these facts, there accrues an elevation of the mind such as cannot otherwise be attained. That grand principle of systematic grouping which underlies all his capacities of acquiring knowledge, is roused into vigorous and healthy exercise; his powers of observation, or rather, his capabilities of impression by outward objects, are greatly increased; and, while he is charmed by the stately vista of theoretical truth which reveals itself before him, he is at the same time conscious that his toils have not been unfruitful in practical results.

CHAPTER IV.

OF REASONING OR ARGUMENT. SYLLOGISMS.

§ 1. *Reasoning in General.*

THE desire of the mind for knowledge admits of no satiety: vast though its acquisitions may be, the pursuit is in nowise slackened; and the regions of infinity itself oft yield rich spoils to some aspiring intellect, which, thirsting for new worlds to conquer, has striven to investigate the most mysterious recesses of the universe. This fact is proclaimed in every page of the world's history: the speculations of the philosopher, the actions of the statesman, the harmonious breathings of the poet, all alike bear witness that the watch-word "progress" is stamped indelibly upon the human mind. If, then, we consider that in our souls there is implanted a faculty which irresistibly carries us forward to the acquirement of new truths, we shall not be surprised when we discover that there are also implanted certain natural laws, which serve to control and guide that faculty in the manner best adapted for the attainment of its ends. Accordingly, since these laws exist, and are the same in all minds, it results that the method of acquiring knowledge is identical in every case.

Now, information may be obtained in three different ways: by the presentment to our minds of the various objects of thought, thus inducing the formation of ideas; by the comparison of ideas, which enables us to make judgments; and by the comparison of judgments for the purpose of arriving at some new truth. The two former of these processes have hitherto engaged our attention exclusively; we have therefore now to investigate the latter, which, of all the mind's

actions, challenges our observation in the most marked manner.

Reasoning, then, consists in arriving at some new truth, from a consideration of other truths already established. These truths it is evident may be expressed in numberless ways, as also may the truth to be inferred; but whenever an act of reasoning is put into words, it will always be found possible to separate it into two portions, one expressing some admitted truths, the other some truth resulting from them. Thus the mere arrangement of the argument (as an act of reasoning when expressed in words is termed) matters nothing with regard to the principles involved; and, consequently, in spite of these principles being, as above stated, universal, we everywhere find that reasoning is expressed in whatever manner may be suggested by the circumstances of the case. This it is, which has led to such erroneous opinions as to the true office and nature of Logic; men, distinguished in other respects for their prodigious intellectual power (*e.g.* Locke), having imagined that because Logic alters the loose, popular *arrangement* of arguments, into a form better adapted for elucidating the principles concerned, it therefore is occupied in teaching some particular *method* of reasoning, the laws of which are different to those employed by such as have not studied the science.

§ 2. *Syllogisms. Inference.*

From the preceding remarks it will have been gathered that before entering upon a logical investigation of any act of reasoning, it is necessary that this should be expressed in a certain regular form. Such forms are termed *syllogisms*, and are so constructed as to show the validity of the argument, without any reference to its *matter*, *i.e.*, to the subjects of which it treats: that is to say, the mere manner of expression is such that the new truth, or *conclusion*, is at once seen to be legitimately deduced from the truths already granted, viz., the *premises*.

The act of thus deducing the conclusion from the premises is termed inference, and consists in ascertaining the full purport of the premises. Thus, ascertaining that chlorine is a

gas, and knowing that all gases are elastic, I infer, or conclude that chlorine is elastic. If expressed in logical form, the argument would run thus: "All gases are elastic; chlorine is a gas; therefore chlorine is elastic." It is not, however, always the case that we commence our reflections with the premises, for we frequently first consider the conclusion, under the guise of a question or problem. For instance, suppose in the above case that we wished to know whether chlorine was elastic or not: we might ascertain the truth by examining the substance; and, finding it to be a gas, we should be certain that it was elastic, as previous investigations had decided that all gases were so. Here we see that there are two terms, "chlorine," and "elastic," the agreement or disagreement of which, we were enabled to decide upon by finding some third term, "gas," wherewith they might be respectively compared. This third term is called the *middle* term, and is the very essence of the syllogism; the inference connected with it being accordingly termed syllogistic, or *mediate* inference.

We now arrive at a somewhat interesting question, viz., whether there can be any kind of reasoning other than mediate inference; that is to say, can we from *one* judgment or truth only, *directly* infer some other? Some writers have contended that such a thing is possible, and have accordingly described a species of reasoning which they term *immediate* inference. Others have denied the possibility of this, and assert that in the examples adduced by their opponents, there is no inference or reasoning whatever.

Now the truth would appear to be that the disputed cases are in reality certain examples of *mediate* inference, which possess such strongly marked peculiarities as to distinguish them from all other instances of reasoning, and to lead to the belief that the laws upon which they are constructed differ from those of the regular syllogism.

It will, therefore, be well to consider these arguments apart from the great bulk of reasonings, more especially as owing to the above mentioned views being adopted, logicians have devised rules for the treatment of such cases, to which rules both parties agree. The arguments themselves may be

classed under three great heads or doctrines, viz., *opposition*, *conversion*, and *coincident junction:* these I shall now proceed to investigate, showing in each case the real nature of the argument.

§ 3. *Opposition.*

The relation which exists between any two propositions differing in form, but identical in matter, is termed opposition. Thus, the judgments "All fishes swim," and "No fishes swim," agree as regards their matter, *i.e.*, their subjects and predicates are respectively formed by the same notions; but they differ with respect to form, one being A, or universal-affirmative-attributive, while the other is E, or universal-total-negative: they are accordingly said to be opposed. And here it should be remarked, that in order for opposition to exist, the respective subjects and predicates must, in both propositions, be considered with reference to the same ideas, time, and circumstances. Thus, I might say, "This man is happy," and "This man is not happy," with perfect truth, providing I were alluding to his condition at separate times; but otherwise, the judgments would be opposed to each other.

The doctrine of opposition is based upon an examination of the various forms of propositions, and declares the natural laws which regulate their mutual relations. Take, for example, a proposition in E, "No metals are vaporisable." On analysing this, we arrive at the following results: that the proposition asserts the total exclusion of the class "metals" from the class of "vaporisable substances;" that—since from the nature of things we know there must always be either a total exclusion, or partial inclusion at least of one class in another—accordingly, if the proposition be true, any judgment which asserted an inclusion (even if only partial) of "metals" within "vaporisable substances," would be false; while if the proposition were not true, a judgment of partial inclusion, at any rate, must be correct. The rule, then, that we should deduce from such an examination would be, "Either E or I must be true;" this, when required for formal use, being converted into its equivalent categorical propositions, "The case of E being false, is a case of I being true;" and "the case of I being false,

is a case of E being true." Taking the example given above, we have for the complete syllogism,

The case of E being false is a case of I being true,
The present is a case of E ("no metals are vaporisable") being false;
∴ The present is a case of I ("Some metals are vaporisable") being true.

In logical language, when we assert the truth of any proposition, we are said to *posit* it; when we deny its truth, we *remove* it. Consequently the above rule is thus technically expressed, "From the position of E we may infer the removal of I; from the removal of E we may infer the position of I; and, in both cases, *vice versâ*." The relation thus declared to subsist between E and I, is called contradictory-opposition, and E and I are termed the contradictories of each other.

I have now I trust shown, once for all, that the inference which obtains in cases of opposition, is *mediate*, and may be regularly expressed in the syllogistic form. I shall, therefore, in recounting the remaining kinds of opposition, merely give the usual logical rules for the position and removal of propositions, without discussing their bases, as the student will be able to do this for himself, by following the method of procedure adopted above.*

There are four kinds of opposition: contradictory, contrary, subaltern, and subcontrary.

Contradictory opposition exists only between E and I, although those writers who do not recognise U and Y, describe it as also existing between A and O. The rule of this opposition is, "The position of a judgment infers the removal of its contradictory; the removal of a judgment infers the position of its contradictory." It has been fully explained above.

Contrary opposition exists between those pairs of judgments which may be false together, but cannot at the same time be true. These are A and E, A and U, A and O, A and Y, U and Y, U and O, E and U, and E and Y. The rule is, "The position of a judgment infers the removal of its contrary." Nothing, however, follows from the removal of a judgment. Thus, "All whales are warm-blooded," and "Some

* For further remarks upon this subject see Appendix B.

whales are not warm-blooded," are contraries (A and O): if we admit the former, we must deny the latter, but if we deny the latter, we are in doubt whether to say, "All whales are all the warm-blooded (things)" (U), or, "All whales are (some) warm-blooded" (A).

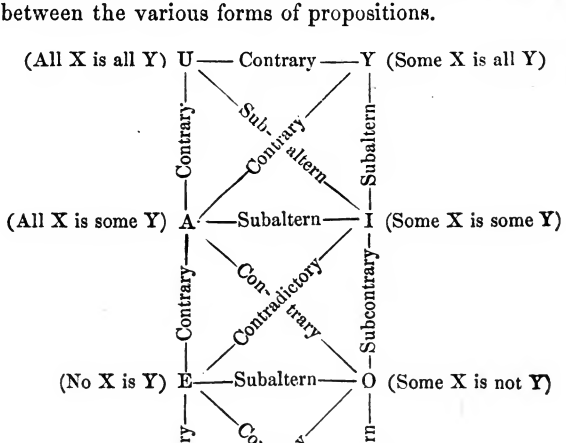
Subaltern opposition exists between certain pairs of judgments which may be true or false together, viz., A and I, U and I, Y and I, E and O, and Y and O. In these cases, that judgment which has most distribution in its terms is called the *subalternant*, its opposite being styled the *subalternate*. Thus I is subalternate to A, U, and Y, while O is so to E and Y. The rule here is that, "The position of the subalternant infers the position of the subalternate."

Subcontrary opposition exists between I and O, which may be true, but cannot be false together; accordingly, the rule in this case is, "The removal of a judgment infers the position of its subcontrary." Y and O have been termed subcontraries by Dr. Thomson, but they would rather appear to come under the head of subaltern opposition, where it will be observed that I have placed them.

It is proper to remark here that the word opposition does not in logical language imply an *incongruity* of two judgments, for we have just seen that there are some cases where opposed propositions may both be true at the same time; it is merely a name given to a certain *relation* existing between the various *forms* of judgments, such relation differentiating as the forms themselves differentiate. Therefore, when Sir William Hamilton states* that "there is no opposition between subcontraries," and that to say so "is a mistake," he appears to have been misled by grafting the ordinary sense of the word "opposition" upon its logical signification; for at a short distance previously we find him declaring opposition to be a relation existing between two judgments which are "opposed or *conflictive*." It is, however, somewhat strange that he should omit to take any notice of subaltern opposition as such, and content himself with merely mentioning it as a relation of subordination. He, it will thus be seen, admits of only two kinds of opposition—contradiction and contrariety.

* "Lectures on Logic," vol. i. p. 261.

It is generally the practice in logical works to give a figure or "scheme" of opposition; and, as this plan is useful in many respects, I subjoin the following, which shows at a glance the relations that have been described above as existing between the various forms of propositions.



§ 4. *Conversion.*

Conversion is the technical name applied to the operation of forming one judgment from another in such a manner that the subject and predicate of the original proposition (the *convertend*) shall be respectively the predicate and subject of the new one (the *converse*). Thus, "Some men of great imagination are all the good poets," is said to be the *converse* of "All good poets are men of great imagination."

Now it is evident that a process of inference takes place here :* let us, therefore, inquire into its nature.

The import of our first judgment is that the class of "good poets" is included, amongst other things, in the class

* See Appendix B.

of "men of great imagination;" and as we know from the natural laws of extension that when one thing is included in another, a part of the object including is equal to the whole of the object included,—we therefore see that in the present case it will be allowable to predicate the entire class of good poets," of "*some* men of great imagination." Accordingly, we frame a general judgment which may be applicable to all cases, and which runs thus, "A case of A is the case of the same subject and predicate being reversed and thrown into the form of Y."

The syllogism, then, will be as follows:—

A case of A is a case of Y containing the same terms as A, but reversed in position,

The present case ("all good poets," &c.) is a case of A;

∴ The present case is a case of "some men of great imagination are all good poets."

The general practice, however, with regard to conversion is the same as that pursued in reference to opposition: instead of framing a syllogism every time we wish to convert a proposition, we employ certain rules which enable us to perform the operation in a more speedy manner. These rules are:—

1. The quality of the converse must be the same as that of the convertend.
2. No terms must be distributed in the converse, but such as are distributed in the convertend.

If the above rules be adhered to, no difficulty need be experienced in converting any proposition whatever; but as a means of facilitating the process still more, the following table will be found useful.

U	may be converted into			U
A	,,	,,	,,	Y
E	,,	,,	,,	E
Y	,,	,,	,,	A
I	,,	,,	,,	I
O	,,	,,	,,	η
η	,,	,,	,,	O

One peculiarity of this table will be at once noticed by the student: I allude to the employment of the form η. This is necessitated by the consideration that if we follow the rules

just given, we can only convert O into η; it is, however, a conversion which is never likely to be made, for, as stated in a former part of this work (p. 34), O is "a much more forcible and convenient mode of expression" than η.

The above method of conversion may be termed *simple*-conversion, although this name is usually limited to the conversion of E and I; that of A being called conversion *per accidens*, or *by limitation*, in consequence of a particular proposition being educed from a universal; while O is treated as inconvertible.*

There is another process which is sometimes considered as a species of conversion, and which may well be examined in the present place. It is variously termed conversion by *equipollence*, by *contraposition*, by *negation*,† by *double negation*,‡ and *immediate inference by means of privative conceptions*; § the name which I shall employ will be *privative-conversion*, as this both indicates the nature of the process, and is harmoniously opposed to the term *simple conversion*.

The *modus operandi* of privative-conversion consists in changing the quality of the convertend, and altering its predicate into a corresponding positive or privative conception, according as the case may be. The reasoning process which forms the foundation of the doctrine is as follows. Take some proposition in A, as, "All intellectual men are amiable," and let us think what it is that we know about its terms: the judgment itself makes us aware that "intellectual men" are in the class of "amiable men," but gives us no further information regarding the latter class; we know, however,¶ that it is possible to form a conception which shall include every man not comprised under "amiable men," and that then we may deny the latter of the former: this we proceed to do, and say, "No amiable men are unamiable"—a judgment which supplies us with the desired premiss, and enables us to form a complete syllogism; thus:—

* Here it will be seen that I allude to those writers who only admit A, E, I, and O.

† Whately's "Elements," Book ii. chap. ii. § 4.

‡ Hamilton's "Logic," vol. ii. Appendix V. c. p. 267.

§ Thomson's "Outlines," § 86.

¶ Supra, p. 20.

No amiable men are unamiable,
All intellectual men are amiable;
∴ No intellectual men are unamiable.

This conclusion is the converse required, and is seen to fulfil all the conditions of privative-conversion; that is, its quality is changed, and its predicate is replaced by a corresponding privative-conception.

§ 5. *Coincident Junction.*

When one class is said to be comprised in another we mean that all the members of the former are also members of the latter. Accordingly, these members may be considered as objects which (*inter alia*) are composed of two sets of ideas inseparably connected. We cannot, therefore, add anything to one idea and not at the same time add it to the other: nor for the same reason can we add one of the ideas to anything, without also adding the other. These considerations supply the general principles of what may be termed the doctrine of *coincident-junction*, and which is thus expressed: "From any judgment we may form another by adding some marks equally to the subject and to the predicate; or we may add the subject and predicate as marks to some fresh conception." Thus if "a metal is a solid" be true, we may also infer that "a red metal is a red solid;" or if we admit that "Logic is the science of the laws of thought," we must equally admit that "the study of Logic is the study of the science of the laws of thought." The former of these inferences has been termed "immediate inference by added determinants;" the latter, "immediate inference by complex conceptions." It will, however, be readily seen from the above investigation of the principles involved, that these reasonings may be exhibited in the syllogistic form, as easily as any of the others.

This concludes the discussion of those arguments which are commonly styled immediate inferences; and, accordingly, whenever we have occasion to employ them in any future portion of this work, they will be considered as falling under their own special rules, and not as regular syllogisms. Such a course will be the more convenient as it will be more familiar to the student; for the general laws which constitute the third

propositions of such syllogisms as have been already considered, are so firmly fixed in our minds, that we are scarcely conscious of their existence, until our attention is specially directed to them; and, consequently, it may almost be said that they are never *overtly* employed in the eduction of so-called immediate inferences.

It will of course be understood that these arguments are not limited to a single operation; for it is possible to start with a judgment and successively employ the three processes of opposition, conversion, and coincident-junction, until we arrive at some other proposition which may satisfy our requirements. Such a proceeding is sometimes said to be merely a determination of a proposition's full signification; but this may be said in effect of all reasoning whatever, for "an *extension* of any science through Logic is absolutely impossible; as by conforming to logical canons we acquire no knowledge, receive nothing new, but are only enabled to render what is already obtained, more intelligible by analysis and arrangement."*

§ 6. *Mediate Inference formally expressed as such.—Its Divisions.*

When an act of reasoning is fully expressed in words, *i.e.*, if the three judgments be articulately stated, we have what is termed a syllogism. But as we saw, when treating upon propositions, that these are of three kinds, categorical, conditional, and disjunctive; so in like manner are syllogisms divided, according as they contain these respectively. Thus the syllogism, "All A is B; C is A; therefore C is B," is *categorical;* "If A is B, C is D; A is B; therefore C is D," is *conditional;* and, "Either A is B, or C is D; A is not B; therefore C is D," is disjunctive.

Now the two latter species of syllogisms may always be reduced to the former when occasion requires, and therefore an examination of the necessary laws of reasoning, together with the systematic arrangement induced by these laws, will best find place under the head of categorical syllogisms. Accordingly, in the following analysis, I shall speak simply of the

* Hamilton's "Logic," Lect. iii. p. 44.

arguments so denominated; this plan being consonant with that pursued when judgments were discussed.

§ 7. *The Fundamental Law of Mediate Inference.*

"Thought," says Sir W. Hamilton, "is the cognition of any mental object by another in which it is considered as included; in other words, thought is the knowledge of things under conceptions." This accords with what I have already stated concerning the grand principle of classification which underlies our faculties of acquiring knowledge; and prepares us to appreciate the fundamental law of mediate inference, which is as follows:—"*Whatever belongs or does not belong to the containing whole, belongs or does not belong to each and all of the contained parts.*"* This law, commonly called the "*dictum de omni et nullo*," we owe to the commanding genius of Aristotle, who first placed Logic upon a sound and durable basis. It is not, however, to be understood that this *dictum* is *directly* applicable to every case of reasoning; the assertion merely being that the validity of any argument is *ultimately* referable thereto.†

For practical purposes men seldom ascend to general and fundamental truths, but devise a system of rules which, being immediately applicable, may obviate much of the inconvenience and delay that would otherwise ensue. Hence it is that logicians have developed Aristotle's *dictum* into the following *proximate* canon. "If two notions agree either wholly or in part with one and the same third, they agree with each other; but if one of them is agreed and the other disagreed with the same third, they disagree with each other." This canon is, however, differentiated still further, thus:—

1. *A syllogism must contain three, and only three, terms, constituting three, and only three, propositions.* The force of this rule is at once evident when we consider that the object sought to be attained by syllogising, is to determine the agreement or disagreement of two notions by respectively comparing

* Hamilton's "Logic," Lect. xvii. p. 321.

† Some objections having been raised by Mr. Mill and others to this account of the fundamental law of mediate inference, I have discussed the question at greater length in article C of the Appendix.

LIBRARY OF THE

them with a third. This, of course, could not be done if we employed more or less than the three terms, or formed more or less than the three judgments.

The names of these terms depend upon their position in the syllogism. The predicate of the conclusion is called the *major* term; the subject of the conclusion is called the *minor* term; while the third notion with which the two former are each compared is styled the *middle* term. In like manner are the premises named, that in which the major term is compared with the middle being the major premiss; the other, the minor premiss.

Much objection has been taken to this employment of the words major and minor on account of their ordinary signification being respectively "greater" and "smaller," whereas it sometimes happens that the minor term is in reality *greater* than the major term, or that we are unable to compare them together as regards their extent. There is no doubt that these names were originally imposed from their representing the facts of the case in one particular form of syllogism which was considered the most perfect; but as they have continued to be used by numerous logicians who were well aware of how the matter stood, it must be inferred that "major" and "minor," when used logically, have merely a technical meaning as distinguishing the terms of the conclusion, and not as implying any relative degree of amplitude. A parallel case is to be found in the use of the word "opposition" (see p. 41). In consequence of such objections, the premises of a syllogism have been variously re-named, the appellations of *proposition*, *lemma*, and *sumption*, being bestowed upon the major premiss, while the minor is known as the *assumption*, *subsumption*, or *hypolemma*.

2. *The premises must not both be negative.* This follows from the consideration that a term can only show the relation of agreement or disagreement subsisting between two others, in so far as it is applicable to one of them at least. If, for instance, we were first to say, "No mathematician is a good moral reasoner," and then that "Shakspeare was not a mathematician," these statements would give us no grounds of comparison between the notions of "Shakspeare" and "good

moral reasoner." We should still be uncertain as to whether the latter might or might not be predicated of the former.

3. *If either of the premises be negative, the conclusion must also be negative;* for this is precisely the case stated in the second portion of the proximate canon above laid down, viz., "If one notion is agreed and another disagreed with one and the same third, they disagree with each other." Thus, from the premises, "no matter is imponderable," and "all gases are matter," we can only conclude that "no gases are imponderable;" for the attribute of imponderability was totally denied of matter, which contains, *inter alia*, all gases.

4. *When the premises are affirmative, if either of them be attributive, the conclusion must also be attributive.* Since a substitutive premiss implies a *total* identicality in extent of the middle term with one of the terms of the conclusion, and an attributive premiss implies only a *partial* identicality of like nature, it follows that between the terms of the conclusion a *partial* identicality of extent is all that can be inferred. An example of this will be found in the following syllogism:—

Compounds are all bodies which may be resolved into simpler forms (U),
Sugar is a compound (A);
∴ Sugar is a body which may be resolved into a simpler form (A).

5. *The middle term must be more than distributed in the premises, both taken together.* For if this were not the case we should have no real inference whatever; as witness this apparent syllogism—

Some beautiful objects are pictures,
Some hideous objects are pictures;
∴ Some hideous objects are beautiful.

Here the two premises are in the form I, which we know does not distribute the predicate, this, in the present case, being the middle term "pictures." Accordingly, the major and minor terms may, for anything the form of expression can tell us, be compared with different portions of the same thing; and this, being equivalent to employing *two* middle terms, would violate the first rule, which prohibits the appearance of

more than three terms altogether. Of course it might so happen that when premises of the above nature were used, we arrived at a true conclusion, as in the following case :—

Some beautiful objects are pictures,
Some valuable objects are pictures ;
∴ Some valuable objects are beautiful.

This conclusion would, however, still be considered as invalid, that is, as not following directly and inevitably from the premises ; for Logic, it will be remembered, regards not the *matter*, but merely the *form* of reasoning.

Usually the middle term is distributed in one of the premises at least; we can then tell at a glance that the rule now under discussion is not violated. Take, for example, the syllogism—

All the metamorphic rocks have been subjected to the action of heat,
Gneiss is a metamorphic rock ;
∴ Gneiss has been subjected to the action of heat.

The major premiss being A, distributes the middle term ; and as this must be again mentioned in the minor premiss, it will necessarily be more than distributed, and will not affect the validity of the conclusion.

Sometimes, however, we meet with a syllogism whose premises contain the middle term in such a manner as to show that the portions employed in each, if added together, would give more than the whole ; *e.g.*—

Twenty per cent. of these knives are bad,
Ninety per cent. of them are apparently well-made ;
∴ Some of these apparently well-made knives are bad.

In this case suppose that the notion "bad" coincides with the entire portion of "these knives," with which "apparently well-made" does not ; such portion being only ten per cent. would still leave a further extent of ten per cent. to be accounted for, and this it is evident must come out of the "ninety per cent. ;" so that we are sure that the notions "apparently well-made," and "bad," must correspond to the extent of ten per cent. at least : this is asserted in the conclusion.

It will in this place be opportune to remark that much con-

fusion frequently results from the use of an *ambiguous* middle term, thus :—

Capes are articles of clothing,
Some tracts of land are capes ;
∴ Some tracts of land are articles of clothing.

This syllogism is *logically* correct, that is, in form ; but if we examine its matter, we shall see that it contains two middle terms, for in the major premiss one kind of "cape" is spoken of, while in the minor, another kind is alluded to. The discussion of such cases will be further conducted when we come to examine the subject of fallacies.

6. *In the conclusion no term must be distributed, unless it has also been distributed in one of the premises.* The terms of the conclusion only agreeing or disagreeing with each other in so far as they respectively agree or disagree with the middle term ; they can merely be compared with each other by means of those portions which were found to coincide in any way with the middle term.

All trees are organised beings (A),
Men are not trees (E) ;
∴ Men are not organised beings (E) ;

And again—

Diamonds are combustible (A),
Some precious stones are diamonds (I) ;
∴ All precious stones are combustible (A).

In the former of these syllogisms we have an *illicit process* of the major ; that is, the major term is distributed in the conclusion without being so in its premiss : in the latter there is, in like manner, an illicit process of the minor. The valid conclusions which might be inferred would respectively be "men are not *some* organised beings" (η), and "*some* precious stones are combustible" (I).

By the six foregoing rules may all syllogisms be tested to ascertain whether they are real or only apparent,—whether the reasoning is correct, or incorrect. They are of great practical importance, as they enable us to dispense with the reduction of many syllogisms into a form where the dictum of Aristotle might be *directly* applied ; but, as already stated, they must only be considered as proximate differentiations of one fundamental truth.

§ 8. *Of Figure.*

In order to facilitate a full examination of syllogistic arguments, that is, of arguments formally expressed, logicians have investigated the number of positions which the middle term may assume in the premises, and in accordance thereto, have formed four classes, under which all possible syllogisms may be ranged. These classes they call *figures*, the form of which may be represented as follows; employing P to signify the major term (predicate of conclusion), S the minor (subject of conclusion), and M the middle.

1st Fig.	2nd Fig.	3rd Fig.	4th Fig.
M P	P M	M P	P M
S M	S M	M S	M S
∴ S P	∴ S P	∴ S P	∴ S P

Thus when the middle term is the subject of the major premiss, and the predicate of the minor, we have the first figure; when it is the predicate of both, the second; when it is the subject of both, the third; and finally, when it is the predicate of the major, and subject of the minor, there results a syllogism of the fourth figure.

§ 9. *Remarks upon the four Figures.*

1. The first figure is the most natural and obvious form into which an act of reasoning can fall; the cause of this apparently being that it is the only one in which the Aristotelian dictum will at once and immediately apply. Thus, to give a concrete example—

The rushing of particles to a nucleus causes the body so formed to rotate,

The earth was formed in this manner;

∴ The earth rotates.

This argument, which is employed by the author of "Vestiges of Creation," I have expressed in popular language, but the student will find no difficulty in arranging it according to the model; "All M is P; S is M; therefore S is P."

2. The second figure, though a somewhat distorted method of stating an argument, is yet very useful and ready in certain

cases, where we desire to prove that some distinction exists between two notions, so as to prevent one of them including the other. Suppose, for instance, we wished to prove that a certain substance did not contain the metal sodium; we might employ such a syllogism as the following:—

Any substance containing sodium would give, when burnt, two yellow bands in its spectrum (U),

This substance when burnt does not do so;

∴ This substance does not contain sodium.

Here the middle term forms the predicate of both premises; consequently, the syllogism is of the second figure. If, however, we wished to apply the Aristotelian dictum, it would be necessary to arrange this argument according to the first figure, such an operation being termed *reduction*. It consists in a skilful application of the doctrines of opposition, conversion, and coincident junction. In the present case all that we have to do is to substitute for the major premiss its simple converse, thus—

Any substance which when burnt gives two yellow bands in its spectrum, contains sodium,

This substance when burnt does not do so;

∴ This substance does not contain sodium;—

a syllogism most manifestly of the first figure.

It has been held that in every case the mind unconsciously performs the process of reduction, and that therefore the second, third, and fourth figures are merely elliptical expressions of *trains* of reasoning, the first figure alone being an adequate representation of a *single* mediate inference. This statement, as implying a more *direct* influence than is usually imagined of the dictum upon our minds, is not unworthy of attention; but since a full examination of the question would occupy more space than could be conveniently devoted to the purpose, I shall remain satisfied with having shown that any argument may be overtly expressed in such a manner as to evince its dependence upon the great fundamental law of reasoning.

3. The third figure is of use when we wish to disprove a theory by instancing some example to the contrary. If we wished to combat the assertion that "no bodies except water

ever expand when cooling," we might do so in this manner:—

Bismuth sometimes expands when cooling,*
Bismuth is a body other than water;
∴ Some other body than water occasionally expands when cooling.

The conclusion thus obtained is the contradictory (I) of the theory to be disproved (E), and accordingly our purpose is accomplished. In order to reduce this syllogism to the first figure, we must simply convert the minor premiss, when the whole will run thus—

Bismuth sometimes expands when cooling,
Some other body than water is bismuth;
∴ Some other body than water occasionally expands when cooling.

4. The fourth figure is chiefly remarkable for the offence which it has given to many logicians, who accordingly have been neither sparing nor gentle in their attacks upon it: "tortuous," "unnatural," "perverse," "hybrid," "useless," "clumsy," "a monster," and "a caprice" may be taken as samples of the objections raised to its reception. It will, therefore, be advisable to examine the nature of some syllogism in this figure: take, for instance, De Quincey's† explanation of the non-existence of duelling among the ancient Greeks and Romans, which is as follows:—

No duelling can exist wherever unlimited license of tongue is allowed to anger (E),
Unlimited license of tongue was allowed to anger among the ancient Greeks and Romans (U);
∴ Among the ancient Greeks and Romans duelling could not exist (E).

Here it is objected that the mind naturally expects the converse of the conclusion, in accordance with the tendency of the argument—this leading from "no duelling can exist where certain license is allowed," to "this license was allowed among the Greeks and Romans," and then in all symmetry to "no duelling could exist among the Greeks and Romans."

Now the answer to this is, that the figure of a syllogism

* It invariably expands at the point of solidification.
† Works. Author's Edition. Vol. vii. p. 281.

depending entirely upon the position of the middle *term* in the *premises*, it will not be affected by a change in the relative positions of *conclusion* and premises. We have, therefore, only to state the conclusion first, and then give the premises as our reasons for forming it, when we shall at once obtain a smooth and naturally proceeding argument. Thus, we can say "Among the ancient Greeks and Romans duelling could not exist; for this is impossible where unlimited license of tongue is allowed to anger, which was the case in Greece and Rome;" than which a more harmonious expression could not easily be found.

In like manner, if we take mere arbitrary symbols to represent the three terms, we shall still have a perfectly clear syllogism, *e.g.*—

No S is P (conclusion);
for No P is M (major premiss),
and M is all S (minor premiss);

the meaning of which is, that none of the objects comprised by S are included by P, since the latter is totally excluded from M, which contains the same objects as S.

At the same time, however, that the fourth figure is thus shown to be perfectly legitimate and unforced, it may be readily conceded that it is but seldom used, as from the same premises and the converted conclusion we can form a syllogism of the first figure: thus, "M is all S; no P is M; therefore no P is S;" which being, as it were, more familiar to the mind, is oftener suggested.

The formal reduction of syllogisms like the above to the first figure, is effected by simply converting both premises; *e.g.*—

No M is P,
All S is M;
∴ No S is P

§ 10. *Of Mood or Mode.*

The arrangement of the propositions of a syllogism with reference to their quantity, quality, and relation, is termed the *mood* or *mode* of the syllogism; and as we are in possession of symbols which fully express the form of a proposition, we can at all times represent the mood by the arrangement

of these letters: the conclusion, it is well to remark, being always placed last.

Now as there are eight kinds of propositions, viz. U, A, E, η, Y, I, O, and ω,—it follows that five hundred and twelve forms of syllogisms or moods may be made. Most of these, however, do not constitute valid arguments, and therefore we must reject them; *e.g.* A O A has an *affirmative* conclusion, though one of its premises is *negative;* E O O has *both* premises *negative;* I I I has either the *middle undistributed* or else an *illicit process;* and so on in numerous other cases. In like manner some moods are admissible in one figure, but not in another; thus, A I I is valid in each of the first and third figures, but in the second and fourth the middle term would be *undistributed.*

§ 11. *Table of Valid Syllogisms in each Figure.*

From the foregoing considerations it will be evident that a table may be constructed which will show all the valid syllogisms falling under each figure; and as such a table is of great practical use, I have drawn up the following:—

TABLE OF MODES.

Fig. I. Aff.	Fig. I. Neg.	Fig. II. Aff.	Fig. II. Neg.	Fig. III. Aff.	Fig. III. Neg.	Fig. IV. Aff.	Fig. IV. Neg.
A A A	E A E	A U Y	A E E	A A I	E A O	A A I	A E E
A I I	E I O	A Y Y	A O O	A I I	E I O	A U A	E A O
A U A	E U E	. . .	E A E	A U A	E U E	A U Y	E I O
A Y I	E Y O	. . .	E I O	A Y A	E Y E	. . .	E U E
			E U E	. . .	. . .	. . .	E Y E
			E Y O			. . .	E Y O
I U I	O U O	I U I	. . .	I A I	O A O	I A I	
I Y I	O Y O	I Y I	. . .	I U I	O U O	I U I	
U A A	U E E	U A A	U E E	U A Y	U E E	U A Y	U E E
U I I	U O O	U I I	U O O	U I I	. . .	U I I	U O O
U U U	. . .	U U U	. . .	U U U	. . .	U U U	
U Y Y	. . .	U Y Y	. . .	U Y A	. . .	U Y A	
						U Y Y	
Y U Y	Y E E	Y A A	. . .	Y A Y	Y E E	Y I I	
Y Y Y	Y O O	Y I I	. . .	Y U Y	. . .	Y U A	
		Y U A				Y Y I	
		Y Y I					

The above table is arranged alphabetically, so as to facilitate reference, and enables us at once to determine the validity or invalidity of any syllogism whose figure is known; for if legitimate, it will be found in its proper position, while if inadmissible, it will be absent.

The propositions η and ω have been omitted from this table on account of their small importance (see p. 34). It may also be proper to remind the student that in most of the older treatises on Logic he will find tables of judgments which differ materially from the one above given, inasmuch as they only recognise the four propositions A, E, I, and O. The usual form in which such a table is given consists of the following four mnemonic Latin verses:—

Fig. I. Barbara, Celarent, Darii, Ferioque, *prioris;*
Fig. II. Cesare, Camestres, Festino, Baroko, *secundæ;*
Fig. III. *Tertia*, Darapti, Disamis, Datisi, Felapton, Bokardo, Feriso habet: *quartâ* insuper addit
Fig. IV. Bramantip, Camenes, Dimaris, Fesapo, Fresison.

These lines, or rather the first three, were the invention of Pope John XXII., whose work upon Logic, under his name of Petrus Hispanus, enjoyed great celebrity. To each of the four figures it will be observed that a verse is appropriated, consisting chiefly of a number of names distinguished by capital letters,* and containing three vowels; the vowels thus employed serve to indicate the mood of the respective syllogisms. For instance, the syllogism "all M is P; all S is M; therefore all S is P," is said to be in the mood *barbara*, which signifies A A A in Fig. I. The *consonants* of the various moods are intended to assist the process of reduction; the *initial letters* show that each mood must be reduced to that mood in the first figure which is similarly characterised: *s* indicates that the proposition immediately preceding is to be *simply* converted (in its old acceptation; see p. 46); *p* that it is to be converted *per accidens*, except in the mood *bramantip*, where it denotes that the conclusion (I) will, when the syllogism is reduced, become A; *m* that the premises are to be transposed; and *k* that the contradictory of the con-

* Tertia, in the third verse, is merely employed for the sense of the expression, and is not a mood.

clusion is to be substituted for the immediately preceding proposition. The two moods, however, in which *k* occurs (*baroko* and *bokarko*) may be more simply reduced by employing the process of privative conversion; they will then become *ferio* and *darii* respectively.

An example will perhaps assist in rendering the above description intelligible. Let us take a syllogism in *disamis*; thus,—

Some rocks have been formed by the action of water (I),
All rocks are solid (A);
∴ Some solid things have been formed by the action of water (I).

Here the *m* indicates that the premises must be transposed, the major and conclusion being simply converted in accordance with the requirements of *s* and *s*. When this is done, we obtain the following:—

All rocks are solid (A),
Some things which have been formed by the action of water are rocks (I);
∴ Some things which have been formed by the action of water are solid (I);—

which is a syllogism in *darii*, that mood of the first figure which was indicated by *D*, the initial letter of *disamis*.

I have thought it advisable to enter at some little length upon this subject, as these ancient names of moods are not confined to logical works, but are often to be met with in old authors; in addition to which, it might be expected that in a work like the present, of professedly a practical character, some notice would be taken of a method so universally followed. In fact, the perfect adaptation of the above quoted lines to their purpose, would alone render them deserving of mention; for, as Sir William Hamilton observes, "it must be confessed that, taking these verses on their own ground, there are few human inventions which display a higher ingenuity."

It must also be observed that so far from the method just described being out of date and obsolete, it may still be applied in many cases; the only difference between it and the table of judgments given in the present volume, being

that the latter is much more complete, containing not only all that the A, E, I and O system includes, but many other syllogisms in addition.

§ 12. *Induction and Deduction.*

We have now seen that all acts of mediate inference when formally expressed, *i.e.* all syllogisms, may be systematically arranged and discussed under the two heads of mood and figure. There are, however, some further divisions of syllogisms which require our attention; the first of these being that into *inductive* and *deductive*.

The distinction between these two methods of reasoning may be thus expressed: induction is the process of forming a general law; deduction, that of applying a law so made to some particular case or cases. Or, in other words, induction consists in reasoning from the *parts to the whole;* deduction, in reasoning from the *whole to the parts.* In *formal* Logic, however, this distinction is comparatively unimportant, as will be seen from the following considerations.

Take some inductive syllogism, as follows:—

Oxygen, chlorine, and steam are elastic (A),
Oxygen, chlorine, and steam are all gases (U);
∴ All gases are elastic (A).

Here we see that from predicating "elastic" of the various parts "oxygen, chlorine, and steam," we are enabled to predicate it also of the whole thus constituted, viz., "gases." It is, therefore, evident that the general law or truth upon which the validity of such a syllogism depends, may be thus expressed:—"That which belongs, or does not belong, to each and every one of the parts, also belongs, or does not belong, to the whole." This law has been declared to differ from the *dictum de omni et nullo*, which, the student will remember, is to the following effect: "That which belongs, or does not belong, to the whole, also belongs, or does not belong, to each and every one of the parts." Now if we admit the difference thus asserted—that is to say, if we admit that these two laws are "equally necessary and *independent*" *—then we must, in

* Hamilton's "Logic," vol. i. p. 321. The italics are my own.

addition, admit that the division into inductive and deductive syllogisms is imperatively called for, since each species of reasoning will have been shown to rest upon separate fundamental* laws.

That this independence, however, does not exist, may be shown by a few reflections based upon the nature of what we understand by the notion of a "whole." In the case under examination the "whole" of which we speak is the conception "gas." This, as the student will recollect from what was said in a previous chapter, is the result of our comparing various bodies together, and ascertaining those attributes in which they are all agreed; the set of attributes so obtained being then abstracted to form the idea, and receive the name of "gas." Consequently, when we say "gases," we think of a class whose members are, *not various individual objects*, but *various similar sets of attributes* existing in separate bodies or objects, viz., "oxygen, chlorine, and steam;" and when we say that what may be predicated of the class "gases," may also be predicated of each of its members, we mean that the attribute "elasticity," for instance, may be predicated of oxygen, chlorine, and steam, not as *individual objects*, but as *separate and similar sets of attributes;* or, in other words, we imply that each set of attributes must be capable of forming the idea "gas" in our minds, and must, consequently, be of similar constitution with the remainder. In like manner, when we say that whatever may be predicated of each member may be predicated of the class "gases," we mean that whatever attribute is common to oxygen, chlorine, and steam must form part of that *set of attributes* which is called "gas;" that is, we imply that oxygen, chlorine, and steam, *considered as definite sets of attributes*, are of similar constitution, and must consequently each be capable of forming the same idea, "gas," in our minds. Now these two expressions, which are thus seen to have almost identical meanings, are the self-same laws which have been spoken of as independent of each other, this statement, therefore, is seen to be incorrect, and, accord-

* As regards the use of the word *fundamental* in this place, see Appendix C.

ingly, we need not consider the distinction between the processes of induction and deduction as more than a logical trifle.

It must here be rigidly borne in mind, that the above remarks only apply to induction and deduction when considered as divisions of *pure* Logic; for when we come to treat upon *applied* Logic, it will be found that another kind of induction exists, which necessitates a particular mention, and which is of very great importance. The difference between these two kinds of induction is closely connected with a fact which the student has doubtless observed, viz., that the minor premiss of our inductive syllogism is obviously incorrect, for so far from oxygen, chlorine, and steam being *all* gases, they only constitute an exceedingly small portion of the class. This brings us to the consideration that in formal Logic we have nothing at all to do with *truth* or *falsehood;* we can only ascertain whether a conclusion *legitimately* follows from premises already *granted.* Accordingly, we merely look upon the minor premiss with reference to its *form, i.e.,* its quantity, quality, and relation, and not as regarding its *matter,* viz., the *reality* and *nature* of the notions composing the subject and predicate: thus, for all purely *logical* purposes, the proposition might be replaced by "X, Y, and Z, are all S" without in the least interfering with the reasoning process. Applied Logic, on the contrary, takes into account the relative natures of the objects furnishing notions, and would construct the syllogism in the following manner:—

Oxygen, chlorine, and steam are elastic (A),
Oxygen, chlorine, and steam are gases (A);
∴ *All* gases are elastic (A).

Here it will be seen that the minor premiss is indeed *true,* but then there is an *illicit process* of the minor term, so that the syllogism cannot be admitted as *formally* valid.

The deductive syllogism corresponding to our inductive example would be as follows:—

All gases are elastic,
Oxygen is a gas;
∴ Oxygen is elastic—

where the general law is applied to a particular case.

§ 13. *Extension and Intension.*

In a former chapter it was explained that a proposition might have its meaning regarded from different points of view, according as the subject and predicate were regarded intensively or extensively. Thus, when we say, "All fluids are compressible," we mean not only that the attributes of "compressibility" are among the attributes of every "fluid" (intension), but, also, that the class of "compressible substances" numbers in its ranks all "fluids" (extension). This differentiation of meaning, in like manner, finds place among arguments, and thence has arisen a distinction of syllogisms into *extensive* and *comprehensive* (intensive). An extensive syllogism is of this nature—

Motion is immaterial,
Heat is motion;
∴ Heat is immaterial,—

and would be thus interpreted:—

Motions are contained in the class of immaterial objects,
Heat is contained in the class of motions;
∴ Heat is contained in the class of immaterial objects.

The same syllogism, if stated comprehensively, or intensively, would run as follows:—

Heat is motion,
Motion is immaterial;
∴ Heat is immaterial;—

and its meaning, when broadly stated, would be this:—

Heat comprehends in it the attributes of motion,
Motion comprehends among its attributes those of immateriality;
∴ Heat comprehends the attributes of immateriality.

An examination of these four syllogisms will reveal their dependence upon each other; all of them being evidently the same result of the same process of reasoning. This is rendered clear by a brief analysis of the import which attaches to predication. We say, for instance, that "motion is immaterial," and in doing so we state that a certain relation of congruity exists between two compound ideas: "*motion*," which consists of two sets of attributes, viz., the generic feature "immateriality" and certain specific differences; and "*immaterial*

objects," which likewise is duplicate, containing the notion "immateriality" *per se*, and the notion of "immateriality" indefinitely repeated, as existing in combination with various sets of specific differences. It therefore results that the *relation* implied by our predication is also *compounded*, its constituents being, that motion is an immateriality united with certain distinguishing marks; and that motion is capable of producing on the mind, together with other impressions, the same idea that immateriality *per se* would do. These two relations it will easily be seen are those of extension and intension. But another fact remains to be noticed: that although the two ideas and relations are thus shown to be *compound*, yet the union of their respective parts is so intimate that they cannot be separated. We are unable to resolve the idea "motion" into its two sets of attributes, "immateriality" and "specific differences," so as to think of these separately, and at different times: we are also unable to divide the idea "immaterial objects" into "immateriality" *per se*, and "immaterialities" respectively combined with distinguishing attributes; and, finally, we are unable to think of one of the relations above described without also thinking of the other. The utmost we can do is to bring one portion of the compound idea, or relation, into greater prominence than its fellow, by concentrating our attention *as much as possible* upon the chosen part; it being remembered that we cannot so concentrate the *whole* of our attention, and, therefore, we must always, in some measure, be impressed by the less important constituent.

These observations, if taken in conjunction with those contained in the section upon induction and deduction, will, it is hoped, afford an intelligible and clear view of the manner in which the mind acts when comparing notions and judgments; and as the operation is always identical, being, though complex, yet irresoluble, it follows that the only useful, or, strictly speaking, admissible division of judgments and reasonings, is that which merely refers to their form. Hence, in formal Logic the distinction between the processes of extension and comprehension must, like that between induction and deduction, be considered as of trifling consequence.

§ 14. *Denomination.*

When speaking of the interpretation of the copula, I mentioned that another mode of doing so had been suggested, in addition to those connected with the doctrines of extension and intension. This was the interpretation of *denomination*, and is as applicable to arguments as to propositions: for example, the syllogism—

All planets are stars,
Mercury is a planet;
∴ Mercury is a star,

may be thus translated:—

Planets may be called stars,
Mercury is a planet;
∴ Mercury may be called a star.

This interpretation is, of course, merely verbally significant, and is not intended to imply any approach to a radical, or even formal difference between the syllogisms. The doctrine, if doctrine it may be called, must, therefore, be received as nothing more than a practical hint for turning a syllogism to some special account, and as such belongs properly to applied Logic. Former usage, however, is my excuse for placing it here.

§ 15. *Syllogistic Arrangement of Propositions.*

Before concluding the subject of pure-categorical syllogisms, it will be advisable to mention a matter about which the student might otherwise entertain an erroneous opinion. I allude to the *order* of the three propositions constituting a syllogism. It will have been observed that the usual course pursued is to place the major premiss first, the minor next, and the conclusion last; and it may consequently be thought that this order is the one most in accordance with natural laws. Such, however, is not the case; the arrangement in question being merely an arbitrary practice adopted by logicians in order to facilitate their expositions of the science.

In fact, it frequently happens that the conclusion occurs to the mind as a problem or thesis, which requires certain judgments (premises) to be formed, in order that its validity

may be apparent. Thus, I might suspect a certain gas to be hydrochloric acid, but in order to be sure it would be necessary for me to find some *proof* of this. Accordingly, knowing the general law that ammonia produces white fumes only when brought into contact with hydrochloric acid, I should proceed to test the suspected gas in this manner; and, the anticipated result following, I should be enabled to construct the syllogism :—

This gas is hydrochloric acid;
Because, It produces white fumes with ammonia,
And, Everything which does that must be hydrochloric acid.

Here the premises and conclusion are reversed. Again, some fact comes under our notice, such as, "This metal takes fire upon touching water;" we make inquiries, and find that "The only metal behaving in such a manner is potassium;" hence we draw the conclusion that "This metal is potassium." An argument so expressed is a syllogism of the first figure, but with the premises reversed. Accordingly, it thus appears that there is no natural and definite *order* of judgments; it cannot, therefore, be said that any arrangement is incorrect, or alone correct, the disputes between logicians upholding different models being so many lost words, we can scarcely say arguments.

§ 16. *Conditional Syllogisms.*

We have now to consider the case of syllogisms whose constituent propositions are not all pure-categoricals; and first we will examine those in which one or more *conditional** judgments appear, the argument being then termed a conditional syllogism.

Now these reasonings may be treated in two ways—practically, and theoretically; that is to say, their own special canons or proximate rules may be applied to them as they stand; or they may be reduced to categorical syllogisms, when, of course, they immediately fall under the laws which

* I omit *modal* propositions, as these cannot be treated otherwise than as pure-categoricals. See p. 28.

have been analysed in the foregoing pages. And, first, as they stand.

Every conditional proposition consists of two parts—the antecedent and the consequent—between which a certain relation is asserted to exist. These parts are both distinct judgments, the relation being that the consequent depends upon the antecedent in such a manner as to necessitate the inference of the former if the latter be granted; *e.g.*, "If the anchor holds out, the ship will be saved," where "If the anchor holds out" is the antecedent, "the ship will be saved" is the consequent, and the relation asserted is, that if we admit that the anchor *will* hold out, then we must also admit that the ship will be saved. A complete syllogism having such a proposition for a premiss, would be of the following form:—

If the anchor will hold out, the ship will be saved,
The anchor will hold out;
∴ The ship will be saved.

In cases where *both* the premises are conditional, then the conclusion must be conditional also, *e.g.*—

If the anchor will hold out, the ship will be saved,
If the storm does not increase, the anchor will hold out;
∴ If the storm does not increase, the ship will be saved.

Now, from a consideration of the relation subsisting between the antecedent and consequent of a conditional proposition, logicians have devised two practical rules, which suffice to determine the validity of any conditional syllogism without reducing it to a categorical form. These are:—

1°. *If the antecedent be granted, the consequent may be inferred;* for this is merely to state the nature of the assertion made by the form of the proposition. Nothing, however, follows from granting the consequent: thus, in the proposition "If he is truly wise, he will be happy," we must infer that he will be happy, if we admit that he is truly wise; but admitting him to be happy will not prove him to be wise, as it is possible for an ignorant person to enjoy himself.

2°. *If the consequent be denied, the antecedent may also be denied.* This follows from the consideration that the truth of the consequent is necessitated by that of the antecedent, so that if the latter were true, the former would be so too.

If, for example, we deny the consequent of this proposition, "If he be shot through the heart, he is dead," and say that he is not dead, we may evidently infer that he is not shot through the heart; but to deny the antecedent would not enable us to say that he is not dead, because he may have been killed by many other causes.

These two laws have given occasion to a division of conditional syllogisms into two moods, viz., the *ponent*, wherein the antecedent is granted, and the *tollent*, where the consequent is denied. These moods are reciprocally convertible, as may be seen from the following example:—

If the moon is not shining, the night is dark,
The moon is not shining;
∴ The night is dark.

This is in the ponent mood; but if we wish to make it tollent, we may do so by reversing the hypothetical, and duly negating, thus:—

If the night is not dark, the moon is shining,
The moon is not shining;
∴ The night is dark.

These moods are also termed constructive and destructive, answering respectively to ponent and tollent.

The second method of treating conditional-syllogisms is, by reducing them to categoricals. Such a proceeding has, indeed, been condemned by high authority* on the ground of its being unnecessary and not always possible. I venture, however, in common with many logicians,† to think that this condemnation is erroneous, as both of the objections urged may be thus disposed of. The reduction is *necessary*, as, by this means, conditional-reasoning being brought under the same *proximate* laws with categorical arguments, is shown to be of exactly the same nature, and so the unity of the reasoning process is maintained; at the same time, however, I do not contend that it is necessary for *practical* purposes, as then the rules above explained would become inept. Again, that the

* Krug's "Logik," p. 258. Bachmann's "Logik," § 89, Anm. 2. Sir W. Hamilton's "Logic," vol. i. p. 342.

† Esser's "Logik," § 99; Wolf's "Philos. Rat.," § 412; Whately's "Elements," book ii. chap. iv., § 6; Thomson's "Outlines," § 73.

reduction is *never impossible*, may be seen from the very case adduced as presenting insuperable difficulties, viz., "If A is C, B is D; but A is C; therefore, B is D;" where we have only to say, "*The case of A being C* is *a case of B being D; the present case* is *a case of A being C;* therefore, *the present case* is *a case of B being D*," and the obstacle is surmounted, the resulting syllogism being a categorical in A A A, Fig. I., or, as the old logicians would say, in *Barbara*. The respective *terms* are here distinguished by being printed in italics.

That these objections should have been brought against the reducing process as applied to conditional syllogisms, is apparently owing, first, to the acceptance of the principle, "Infer nothing without a ground or reason" as a necessary and primary law of thought; and, secondly, to its being lost sight of that a term may be composed of more than one conception. With regard to the first of these causes, it may be observed, that the law there mentioned, called the law of reason and consequent, has been a subject of much discussion among metaphysicians and logicians, but should properly be referred to the former alone. By it the antecedent is explained as being "the complement of all, without which something else would not be," and the consequent as being "the complement of all that is determined to be by the existence of something else." This, which is Sir William Hamilton's explication, given with especial reference to conditional propositions, is, however, too wide and general for application in such cases; since, were we to admit that the consequent "*could* not be" without the antecedent, we must also admit, that by denying the antecedent we may deny the consequent, which is contrary to the second rule above given. It is likewise too wide and general to be considered as a separate law, for if the antecedent be the "*complement of all, without which* something else would not be," it must necessarily be that "something else" itself. Now, a thing cannot be something else; and, therefore, in order to attach any admissible meaning to the definition under question, we must interpret it thus:—"The antecedent is the same thing as the consequent, but from a different point of view," a state-

ment much the same as "a thing is itself," and answering to another primary law, viz., "whatever is, is." * Indeed, Sir William Hamilton's latest views would appear to have been in accordance with those advocated here, as we find him saying, that the law of reason and consequent "should be excluded from logic." †

The second source of objection which led to the statement that some conditionals could not be reduced, probably arose, as stated above, from an incomplete view of the structure of terms. Thus, in the syllogism, "If A is B, C is D; but A is B; therefore, C is D;" it was hastily concluded that there are four terms, A, B, C, and D; but, in so doing, it is assumed that the reasoning process concerns these simple notions; whereas, in fact, it is occupied with the more complex ideas, "A is B" and "C is D." Accordingly, instead of *four* terms, which of course would be incompatible with a categorical syllogism, we have only *two*, and require a third, viz., "the present case," before we can draw a conclusion. This third term is implied in the second premiss, when we say "A *is* B."

During the course of the preceding remarks, the student will doubtless have observed the technical method of reduction employed in these cases. It may be articulately enounced as follows: "Each conditional proposition is to be considered as a universal-affirmative-attributive categorical, with the antecedent for a subject, and the consequent for a predicate." Thus, the syllogism here stated,—

If a body is struck, heat is generated,
But if a meteorite falls into the sun, a body is struck;
∴ If a meteorite falls into the sun, heat is generated,

may be reduced in the following manner:—

All cases of "a body is struck," are cases of "heat is generated" (A),
All cases of "a meteorite falls into the sun," are cases of "a body is struck" (A);
∴ All cases of "a meteorite falls into the sun," are cases of "heat is generated."

* As regards the primary laws of thought, see Appendix C.

† "Discussions," p. 603.

In this way, or by using equivalent expressions, any conditional syllogism may be thrown into the form best adapted for displaying its real import as an act of reasoning.

§ 17. *Disjunctive Syllogisms.*

A *disjunctive* syllogism is an argument in which there is one, or more than one, disjunctive proposition, and may be represented by these formulæ: 1°. "A is either C or D; B is neither C nor D; therefore, B is not A." 2°. "A must be either C or D; but it is not C; therefore, it is D." 3°. "A is either C, D, or E; but it is not C; therefore, A is either D or E." 4°. "Either A is B, or C is D; but A is not B; therefore, C is D," &c. &c.

The import of the disjunctive propositions in all these syllogisms is, that the cases enumerated are the only possible ones, and that they are mutually exclusive; a perfect logical division has in fact been performed. Accordingly, the practical rules which result are—

1°. *From the assertion of one alternative, we may deny all the others; e.g.*, if in the proposition, "All men must be either white, black, red, or yellow," we were to affirm, "These men are red," we might infer that "they are neither white, black, nor yellow."

2°. *From the disjunctive assertion of more alternatives than one, we may deny the rest.* Thus, in the above example, if we were to say, for our second premiss, that "these men are either white or black," we should then conclude that "they are neither red nor yellow."

3°. *From the denial of one, or more than one alternative, we may assert such as remain; directly, if one, disjunctively, if more.* Accordingly, the following syllogism would be valid:—

All poems are either epic, lyrical, or didactic,
The poem of Paradise Lost is neither lyrical nor dadactic;
∴ Paradise Lost is an epic.

The reduction of disjunctive syllogisms to categoricals is similar to that of conditionals. Take, for instance, the syllogism just quoted—it will become:—

Poems which are neither lyrical nor didactic, are epics,
Paradise Lost is a poem which is neither lyrical nor didactic;
∴ Paradise Lost is an epic.

And here it must be stated, that in order to have a true conditional or disjunctive syllogism, it is necessary that the *reasoning* should hinge upon the *consequence* in the one case, and on the *alternative* in the other; for it is possible for a conditional or disjunctive *proposition* to exist in a categorical *syllogism;* thus,

All simple forms of matter are indestructible as such,
If the caloric theory be correct, heat is a simple form of matter;
∴ If the caloric theory be correct, heat is indestructible as such.

In this case, "*If the caloric theory be correct, heat*" must be considered as the minor term, for it is evident that the reasoning is merely a comparison of this, and the major term "indestructible as such," with the middle "simple forms of matter;" leaving the *consequence* of the conditional proposition altogether untouched.

§ 18. *The Dilemma.*

If in a syllogism there be a conditional premiss, whose antecedent or consequent is composed of a disjunctive proposition, such an argument is termed a dilemma, or hypothetico-disjunctive syllogism. Take, for example, the following:—

If the army were defeated, it must either have surrendered or retreated,
But it did neither of these;
∴ It was not defeated.

The rules upon which the validity of such syllogisms depend, are compounded of those referring to both conditionals and disjunctives; thus, 1°. *The antecedent being affirmed, either disjunctively or not, as the case may be, the consequent is also admitted;* and 2°. *The consequent being denied, either disjunctively or not, as the case may be, the antecedent is also denied.*

An argument of the above description is termed a *dilemma*

in consequence of its having two disjunctive members in the consequent of the major premiss: that is to say, it contains a double lemma, or double supposition. If there are three such members, it is a *trilemma*; if four, a *tetralemma*, and so on; but the name *polylemma* is usually applied to those containing more than four. Any one of these would, however, be loosely called a dilemma.

Such is the account commonly given of those arguments to which the name of dilemma is applied; but it is incomplete, as it does not refer to a class of syllogisms which, if anything, would fall more properly under that denomination. I allude to those in which several antecedents and consequents are disjunctively affirmed or denied; *e.g.*—

If he leaps out of the window, he will severely injure himself; if he does not do so, he will be burned,
But he must do either the one or the other;
∴ He must either severely injure himself, or be burned.

Or again—

If this man were happy, he would not be angry; and if he retained his self-command, he would not be excited,
But he is either angry or excited;
∴ He is either unhappy, or has lost his self-command.

In these syllogisms, we see that the major premiss (so to speak) is composed of two distinct conditional propositions, thus being a truer *di-lemma* than the cases previously considered.

All hypothetico-disjunctive arguments may be reduced, either to conditionals or categoricals at pleasure. There is no difficulty in the process, it being merely a judicious combination of the methods already studied, and as a general model, the following formula will be all that is needed. It shows the categorical reduction of a complex-dilemma, that is, where the major premiss is composed of two distinct conditionals.

Syllogism:—

If A is, B is; and if C is, D is,
But either A is, or C is;
∴ Either B is, or D is.

Reduction :—

1°. Take for a major *premiss* the categorical equivalent of the given minor; and for a minor *term*, the denial of the consequent in the *first* conditional of the given major premiss: complete the syllogism, thus

All non-A's are C's,
All non-B's are non-A's;
∴ All non-B's are C's.

2°. Take for a major premiss, the categorical equivalent of the *second* conditional in the given major; and for a minor premiss, the conclusion of the syllogism last formed: the conclusion resulting from these premises, will be the categorical equivalent of the disjunctive conclusion in the syllogism given for conversion: *e.g.*—

All C's are D's,
All non-B's are C's;
∴ All non-B's are D's;
or
Either B is, or D is.

§ 19. *Incomplete Syllogisms.*

When any one of the propositions forming a syllogism is not overtly enounced, such an argument is termed an *Enthymeme.* It will be evident that there is no difference in the *reasoning process* between enthymemes and formal syllogisms, as the premises and conclusion are in both cases the same: the distinction merely consists in the number of judgments that may be actually expressed in words. Accordingly, since there are three propositions in every syllogism, enthymemes are divided into three orders, which respectively suppress the major premiss, the minor premiss, and the conclusion. Examples of them may be thus given :—

The formal syllogism :—

All women are inquisitive,
Julia is a woman;
∴ Julia is inquisitive.

Enthymeme of the first order (the major suppressed) :—

Julia is a woman;
∴ Julia is inquisitive.

Enthymeme of the second order (the minor suppressed):—
All women are inquisitive;
∴ Julia is inquisitive.
Enthymeme of the third order (the conclusion suppressed):—
All women are inquisitive,
And Julia is a woman.

Into one or other of these three forms, nearly all arguments, as popularly expressed, fall; for it is seldom that a person takes the trouble to state a syllogism in full. This elliptical method of overt inference, is most strikingly developed in those arguments which were discussed under the heads of *Opposition*, *Conversion*, and *Coincident-Junction*, where not only is a premiss not expressed, but it is almost *unconsciously* thought; so much so, indeed, that it requires a searching investigation to become convinced of its existence. We need not wonder, therefore, at their being often termed immediate inferences. Conditional judgments too, are frequently of an enthymematic nature, such as, for instance, "If Pegasus be a horse, it must be a quadruped," which manifestly proceeds upon the assumption that "all horses are quadrupeds."

§ 20. *Complex Arguments, or Chains of Reasoning.*

It often happens that we arrive at a conclusion through a string of correlative syllogisms, and when this is the case we have what is termed a *chain of reasoning*. These arguments are, however, generally of an enthymematic form, and are divided according as they suppress the conclusion, or one of the premises, in each syllogism.

Those chains of reasoning, where all conclusions but the one desired are suppressed, must necessarily consist of premises, and this form is known as a *sorites*. It may be of two kinds—first, where the predicate of each premiss is the subject of the next succeeding one, and where the conclusion is the last predicate affirmed of the first subject; this is termed the ascending, regressive, or Aristotelian sorites: and secondly, where the subject of each premiss is the predicate of the next, and where the conclusion is the first predicate affirmed of

the last subject; this is styled the descending, progressive, or Goclenian sorites. The formulæ of these are :—

Aristotelian.	Goclenian.
A is B,	D is E,
B is C,	C is D,
C is D,	B is C,
D is E;	A is B;
∴ A is E.	∴ A is E.

Or, concrete examples may be given, as follows :—

Aristotelian :—

Red is a colour,
A colour is a kind of light,
All light is a kind of motion;
∴ Red is a kind of motion.

Goclenian :—

All light is a kind of motion,
A colour is a kind of light,
Red is a colour;
∴ Red is a kind of motion.

It will have been observed, that the formulæ are entirely affirmative; this arises from the rule that we can draw no conclusion from negative premises. We may, however, have the last premiss of the series negative, but then the conclusion must be negative also, thus :—

Red is a colour,
A colour is a kind of light,
All light is a kind of motion,
No motion is material;
∴ Red is not material.

A sorites containing premises of the above description, may have its validity directly tested by this modification of the *dictum* :—"Whatever belongs, or does not belong, to a given whole, belongs, or does not belong, to each and every one of the parts constituting any whole contained in the given whole." If, however, the premises are of different forms (I, U, &c.), and the reasoning, in consequence, rather complicated, we may readily ascertain the legitimacy of the sorites by a process of dissection; that is, by resolving it

into its constituent syllogisms. The formulæ for this purpose are the following :—

Aristotelian.	Goclenian.
A is B, Minor,	D is E, Major,
B is C; Major,	C is D; Minor,
Minor, (∴ A is C), Conclusion.	Major, (∴ C is E), Conclusion.
Major, C is D;	Minor, B is C;
Conclusion. (∴ A is D), Minor,	Conclusion. (∴ B is E), Major,
D is E; Major,	A is B. Minor,
∴ A is E. Conclusion.	∴ A is E. Conclusion.

From this diagram, it will be seen that each suppressed conclusion forms the *minor* premiss of the succeeding syllogism in the Aristotelian sorites, and the *major* in the Goclenian. Accordingly, if we detect any false mood among the syllogisms, all its successors will be invalid, as depending upon an erroneous premiss.

A chain of reasoning, wherein one, or more than one premiss is suppressed, is termed an *epicheirema*, and may be of three orders ; first, where the *major* premiss of the main syllogism is the conclusion of another syllogism, with but one premiss expressed ; secondly, where the *minor* premiss is similarly characterised ; and lastly, where the conclusion forms the sole expressed premiss of a succeeding syllogism, a second conclusion thus resulting. The epicheirema may also be single, double, or treble, according as it is a combination of one, two, or three orders.

The nature of these arguments will be evident from an inspection of the following examples :—

Single epicheirema of the first order (the major a conclusion) :—

All planets are attracted by the sun ; for they revolve about him as a centre,

The earth is a planet ;

∴ The earth is attracted by the sun.

Single epicheirema of the second order (the minor a conclusion) :—

All birds are oviparous,

The condor is a bird ; for it has wings, feathers, and a heart ;

∴ The condor is oviparous.

Single epicheirema of the third order (the conclusion a premiss :—

Matter is imperishable,
Gold is matter;
∴ Gold is imperishable,
and
∴ Gold is eternal.

Treble epicheirema of the conjoint orders :—

He who is truly wise is just; for he is virtuous,
Aristides is truly wise; for he is led astray by no passions;
∴ Aristides is just,
and
∴ Aristides is happy within himself.

By symbolising, the last epicheirema may be thus extended into complete syllogisms; the propositions in parentheses being those which were suppressed :—

Conclusion.—A is B { (All C's are B's) major. / A is C . . . . minor.

Conclusion.—D is A { (All E's are A's) major. / D is E . . . . minor.

∴ D is B . . . . . minor.
(All B's are F's) major.
∴ D is F . . . . . conclusion.

The two syllogisms whose conclusions form the premises of the main argument, are called *prosyllogisms*, while the syllogism which takes the main conclusion for a premiss is termed an *episyllogism*.

In the strictest view of the science, pure Logic would take no cognisance whatever of incomplete or complex arguments; as in them the inference is not necessitated by the mere form of the expression. Since, however, all *practical* reasoning is of this nature, it would not be advisable to omit its consideration, as one of our objects is to show the universal extent of pure Logic, and also how its laws and principles pervade the whole universe of thought. We cannot, therefore, condemn the practice of logicians, who almost invariably have discussed these reasonings when treating upon the doctrines of logical elements.

§ 21. *Recapitulation.*

We have now concluded our investigation of the principles upon which the reasoning process is based, and of its various products. I shall, therefore, in accordance with my previous practice, briefly recapitulate the principal results at which we have arrived.

Reasoning in general is the eduction of a truth from some truths already established, but of whose full import we are not aware. It, therefore, cannot be an instrument for the *extension* of science, which would involve the discovery of fresh facts, but is of use in the due comprehension and orderly arrangement of our knowledge. It also follows that any processs of reasoning (termed a syllogism) is composed of two parts—the antecedent, or established truths, and the conclusion, or truth educed from them. Now the antecedent invariably consists of two judgments termed premises, but both of these are not always articulately enounced. This gives rise to a division of arguments into two classes; the one comprising certain syllogisms whose major premiss is always suppressed; the other comprising all that remain. The first of these classes is divided under three great heads, viz., *opposition*, or the relation subsisting between propositions which differ in form, but are identical in matter, such relation being either contradictory, contrary, subaltern, or subcontrary; *conversion*, or the transposition of the subject and predicate in a judgment, which may be of two kinds, simple and privative; and *coincident-junction*, or the inseparable union of the attributes in a conception. The second class, composed of formal syllogisms, requires as an essential preliminary of its treatment, the determination of a fundamental law which may decide the validity of all arguments. This law is found to be as follows: "Whatever belongs, or does not belong, to the containing whole, belongs, or does not belong, to each and all of the contained parts;" but, for proximate application, it is developed into this canon, "If two notions agree, either wholly or in part, with one and the same third, they agree with each other; but if one of them is agreed, and the other disagreed with the same third, they disagree with each other,"

which, variously differentiated for particular purposes, enables us to test the legitimacy of any syllogism. This canon formed, we find that all syllogisms whatever are susceptible of two methods of classification; first, with reference to the position of the middle term in the premises, whereby arguments are arranged into four *figures;* and, secondly, with reference to the form of the constituent propositions, the symbols representing these being grouped in threes, and termed *moods.* This distinction of figure and mood is sufficient as regards the form of syllogisms to determine their validity; but some other divisions respecting the import of arguments have a claim upon our notice. The doctrines of *induction* and *deduction* come first, and apparently depend upon different principles,—for induction reasons from the parts to the whole; deduction from the whole to the parts. A close examination, however, shows that, as far as *pure* Logic is concerned, they may be regarded as almost identical. Then follow *comprehension* (intension) and *extension,* which respectively interpret syllogisms as predicating an attribute of a notion, and a genus of a species; but this distinction also fades into obscurity when we reflect upon the irresoluble complexity of our ideas. Lastly, we have *denomination,* which identifies the reasoning process as one of naming; the significance of this interpretation being merely verbal. Having thus obtained a clear notion of the syllogistic theory, by confining our attention to arguments composed of categorical propositions, we proceed to the consideration of those cases wherein we meet with conditional judgments; and, by analysis, we find that they may all be referred to these two rules—1°. "The antecedent being granted, the consequent may be granted;" and 2°. "The consequent being denied, the antecedent may be denied." Next, taking the syllogisms which depend upon disjunctive judgments, we find that the principles involved are those of a perfect logical division; while those arguments which fall under the name of dilemma may be treated by a combination of the rules applicable to each of the two former classes. Lastly, we have to examine the popular method of stating arguments, and find that they either assume the form of *enthymemes,* or syllogisms with one proposition suppressed; or

else that they are expressed as *chains of reasoning*, these being of two kinds—a sorites, or string of premises with one conclusion; and an epicheirema, or syllogism whose premises are the conclusions of prosyllogisms, and whose conclusion is the premiss of an episyllogism.

§ 22. *Conclusion.*

Here, as stated in the introduction, the province of *pure* Logic terminates; and if the student has closely followed the foregoing analysis of its principles, he will be in a position to rightly appreciate its nature and end. Whatever may be the ulterior object for which the mind is cultivated, every person "must have thoughts to arrange, knowledge to transplant, and facts to record;" and the more effectually these can be done, the greater will be the progress. Now, the three great instruments for the above-mentioned processes are, first, Logic; secondly, languages; and lastly, the arts of memory.* Thus the superiority and precedence of Logic in point of utility is apparent: it prepares a sure and solid foundation; it arranges the materials as they arrive in regular courses; and, finally, completes the majestic edifice of a well-ordered mind Here, of course, I allude to the *science* of Logic; that is to say, the knowledge of the formal laws of thought as applied to the treatment of *acquired* information; consequently, we must not suppose that pure Logic will furnish us with powers of observation, or with facts to observe; its sphere being limited to the invigoration of those mental abilities with which we are respectively endowed, and to the elucidation of those truths which have already attracted our attention. It is but the few whom Nature has endowed with great intellectual power; and no amount of Logic, or of mental training, will supply the original deficiency. A Bacon or an Aristotle is born, not made. At the same time, however, the most commanding genius is capable of being raised to a still loftier

* Compare De Quincey, "Works," vol. xiii. p. 25, who advocates these views in a series of Letters, respecting which one can scarce tell whether most to admire their purity of style, their elegance of diction, their cogency of argument, or their subtle play of humour.

elevation; as much so as is the weakest mind. We are not, therefore, surprised to discover that the names of the most sedulous cultivators of Logic are those of the greatest philosophers that have ever lived. From Socrates, Plato, and Aristotle to Bacon; from Kanâda and Gotama to Kant; whether among the academic groves of ancient Athens, the busy haunts of British industry, the tropical luxuriance of eastern climes, or the ponderous reflections of learned Germany, there has ever been a bright succession of eminent men who have devoted their efforts to the investigation of the human mind, its thoughts, their principles, and laws. These principles they have employed, not only as regulators of the intellect, but also as guides and restraints in their search after truth, both moral and physical—such a disposition of the science being what is termed *applied* Logic, which will form our next subject of study.

CHAPTER V.

OF FALLACIES.

§ 1. *Applied Logic in General.*

We have now left behind us the sterile, but grand and impressive realms of theory, and are entered upon the luxuriant regions of practice, where there is everything to interest and to delight, but whose green and smiling soil too often hides a treacherous morass. Here, then, is the opportunity afforded to us of putting our experience to the test, and of determining in what way the rules, which we have been acquiring, may be of service to us.

Now, the ultimate end of all thinking, is the attainment of truth, and therefore, when we have ascertained what are the necessary laws of thought, we should not remain satisfied with this speculative knowledge, but should actively employ it as a means of advancement towards that higher object for which those laws were implanted. This operation it is, which forms the province of *applied* Logic, and which we are now about to consider, although the limits of our space must necessarily preclude any attempt to do more than take a cursory—but I trust, instructive—view of so vast a subject.

I have said that our object now is, to examine into the employment of the formal laws of thought as thought, for the purpose of attaining truth; and since we continually make use of one fact as a means of arriving at another, it follows that the practical application and operation of inference, must occupy much of our attention. Inference, however, may be examined from two points of view, positive and negative; for we must either reason correctly or in-

correctly: it follows, therefore, that the spheres of investigation which present themselves are—first, the essential conditions of, and inducements to, a legitimate inference; and secondly, the causes and nature of an illegitimate inference. The question now comes, which of these subjects shall we first examine? and the *ratio decidendi* must be the *end* which we propose to ourselves: this is the acquirement of truth, and can only be attained by a proper understanding of what constitutes correct inference. But, in order to properly understand what a thing is, we should first ascertain what it is *not;* for, as Bacon says, "Inductio quæ ad inventionem et demonstrationem Scientiarum et Artium erit *utilis*, Naturam separare debet, per *rejectiones et exclusiones debitas;* ac deinde *post negativas* tot quot sufficiunt, super affirmativas concludere." Accordingly, our immediate duty must be to investigate the conditions and concomitants of *incorrect* inference, or "bad reasoning," as it is generally termed.

Every argument consists in drawing a conclusion from certain evidence which has been adduced, and if this evidence be such as to warrant the conclusion, we are said to reason legitimately; if not, the reverse. Now, as no man ever assents to a judgment unless he deems its evidence conclusive, a case of false reasoning can only occur where the evidence, though seemingly just and sufficient, is, in reality, fallacious and deceptive; such an argument is called a *fallacy*.

§ 2. *Classification of Fallacies.*

The true way of comprehending any subject is—as we discovered when treating upon pure Logic—to arrange it in a system constructed upon the principles of logical division and classification. It, therefore, behoves us, if we would make a practical use of the science, to at once arrange the various fallacies under their respective heads, before proceeding to discuss them in detail.

Every syllogism consists of two parts, *form* and *matter:* this enables us to divide all fallacies into two great classes, viz., those whose inference is erroneous, through being informally

expressed ; and those where the premises legitimately imply the conclusion, if the *form* of the syllogism be alone regarded, but where an examination of the *matter* will show the reasoning to be invalid.

Formal fallacies are those which violate the syllogistic canons, and may be subdivided into as many co-ordinate species as there are proximate rules. It will only be necessary, however, for our purposes, to regard the faults of *undistributed middle* and *illicit process.*

Material fallacies may be erroneous, either as regards their terms, their premises, or their conclusion, and are consequently subdivided into these three subaltern genera, viz., *quaternio terminorum,* or syllogisms with four terms ; syllogisms with a *premiss unduly assumed ;* and *ignoratio elenchi,* or syllogisms which do not prove the required conclusion.

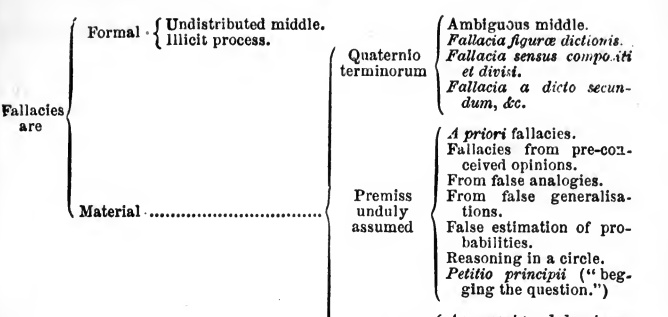
The species of these subaltern genera, may be arranged in accordance with the following considerations :—

1°. *Quaternio terminorum.* This fallacy may arise from the ambiguity of the middle term, so that in the major premiss one sense of the word is used, in the minor, another. Or, for any one of the terms, two words may be employed which are supposed to imply the same meaning, but do not. Or, again, a term may consist of several notions, these being taken together in one judgment, and separately in the other. Or, lastly, a term may be used absolutely in one judgment, and relatively in the other.

2°. *A premiss unduly assumed.* The causes of this may be,—considering certain truths as self-evident which are not so ; forming a judgment from some pre-conceived opinion, false analogy, or false generalisation ; over-estimating the weight of probabilities ; reasoning in a circle; or, taking for a premiss some proposition which is the same as, or implies, the conclusion.

3°. *Ignoratio elenchi.* This occurs whenever appeals are made to the passions, prejudices &c., of men ; when a part is proved instead of the whole ; &c., &c.

The foregoing division may be exhibited in a "scheme," as follows :—



Before we commence the discussion of each of the above fallacies in its order, it may be well to remark that the above division could only be logically perfect, provided we were allowed to make arbitrary distinctions between individual examples of false reasoning; for there are some fallacies which belong to one species equally as much as they do to another. This, in many cases, arises from the enthymematic mode of expression which obtains so universally: were a man, for example, in maintaining the efficacy of imprisonments for life, to argue that "capital punishment is improper," because "it does not tend to make the criminal a better member of society," we must either suppose him to hold that "*all* proper punishments are for the purpose of reformation, as regards the criminal's social behaviour," or that *some* are. In the former case, the complete syllogism would run thus:—

All proper punishments are intended for the criminal's social reformation,

Capital punishment is not so intended;

∴ Capital punishment is improper.

Here the formal reasoning is perfectly valid, but when the *matter* is examined, we see that the major premiss is unduly assumed; for, obviously, imprisonment for *life* is not intended to make the criminal a better member of society, as it starts with the condition that he shall never mix with his fellow-creatures again.

If we adopt the latter of the suppositions stated above, the argument will be as follows :—

Some proper punishments are intended for the criminal's social reformation,

Capital punishment is not so intended ;

∴ Capital punishment is improper ;—

where there is an illicit process of the major term, and, consequently, a formal fallacy.

In cases similar to the foregoing, it must always remain doubtful as to which class they belong ; and, therefore, the division adopted must be considered as only approximatively correct. This state of things, however, obtains in every science, and arises from the necessary imperfection of our knowledge : in chemistry, for instance, it is a moot point as to whether arsenic should be included amongst the metallic or non-metallic elements ; while, in biology, it is almost impossible to draw the line between animal and vegetable life. At the same time, most classifications are correct enough for all practical purposes, if not in strict accordance with the rigorous requirements of theoretical truth. Thus much premised, we shall now enter upon a detailed account of the various species of fallacies.

§ 3. *Formal Fallacies.*

These, as already stated, consist of such syllogisms as violate the canons which have been laid down for the purpose of determining the validity of an argument from its form. The principal species are Undistributed middle, and Illicit process. Examples may be thus given :—

Undistributed middle :—

Negroes are men,
Hindoos are men ;
∴ Hindoos are negroes.

Illicit process :—

All planets revolve round the sun,
All planets are stars ;
∴ All stars revolve round the sun.

The subject of form has been so fully discussed in the preceding chapter, that it will not be necessary to add anything

further upon this point. The following observations, however, taken from Archbishop Whately's "Elements," are of great importance.

"To the present class [formal fallacies] we may the most conveniently refer those fallacies, so common in practice, of supposing the conclusion false because the premiss is false, or because the argument is unsound; and of inferring the truth of the premiss from that of the conclusion. *e.g.*, if any one argues for the existence of a God, from its being universally believed, a man might, perhaps, be able to refute the argument by producing an instance of some nation destitute of such belief; the argument *ought* then to *go for nothing:* but many would go further, and think that this refutation had *disproved* the existence of a God; in which they would be guilty of an illicit process of the major term: viz., 'Whatever is universally believed must be true; the existence of a God is not universally believed; therefore, it is not true.' Others again, from being convinced of the truth of the conclusion, would infer that of the premises, which would amount to the fallacy of an undistributed middle: viz., 'What is universally believed is true; the existence of a God is true; therefore, it is universally believed.' Or, these fallacies might be stated in the hypothetical form; since the one evidently proceeds from the denial of the antecedent, to the denial of the consequent; and the other, from the establishing of the consequent, to the inferring of the antecedent; which two fallacies will usually be found to correspond respectively with those of Illicit process of the major, and Undistributed Middle.

"Fallacies of this class are very much kept out of sight, being seldom perceived even by those who employ them; but of their practical importance there can be no doubt, since it is notorious that a weak argument is always, in practice, *detrimental*; and that there is no absurdity so gross which men will not readily admit, if it appears to lead to a conclusion of which they are already convinced. Even a candid and sensible writer is not unlikely to be, by this means, misled, when he is seeking for arguments to support a conclusion which he has long been fully convinced of himself; *i.e.*, he

will often use such arguments as would never have *convinced* himself, and are not likely to convince others, but rather (by the operation of the converse Fallacy) to *confirm*, in their dissent, those who before disagreed with him."

§ 4. *Material Fallacies: Quaternio Terminorum.*

1°. *Ambiguous middle.* This occurs whenever one sense of the middle term is employed in the major premiss, and another in the minor, thus—

Whoever is nervous is timid,
Hercules was nervous;
∴ Hercules was timid.

The word *nervous* is here used in two senses, viz., "timid" and "strong," and, consequently, the syllogism contains four terms, which, of course, renders it invalid. I have given an example in which the error may be easily perceived, but it must not be supposed from this, that all cases of ambiguous middle are of such a simple character. Indeed, there are many words of common use, which continually give rise to mistaken ideas in consequence of their ambiguity. Thus, the impression is very general, that the "*men of old*" were superior in wisdom and experience to those of modern times; this notion arising from the natural reverence which we feel for the opinions of "*old men*," in consequence of their longer life having enabled them to form a better judgment of the world's course than younger men can do. Of course, when the syllogism is fully expressed—"Old men are worthy of reverence; these men are men of old; therefore, these men are worthy of reverence"—we see at once that the word *old* is used at one time in the sense of *aged*, and at another, as signifying *removed from us by length of time;* and that, accordingly, the reasoning is inconsequent; but then we must remember that arguments, in practice, are elliptical, the premises being oftener hinted at, than articulately stated. A skilful sophist, therefore, will avoid anything like a definition of the terms he employs, or a full expression of his inference; trusting to the various associations, traditions, and prejudices of his hearers to supply such ideas as may be best

calculated to lead them to the desired conclusion. And in like manner, it follows that the most effectual remedy against fallacies of this description, is to insist upon a precise explanation of the sense in which each term is used. That this caution is not unnecessary, will easily be seen if we reflect upon the great number of words which are susceptible of duplicate, triplicate, &c., interpretations; *e. g.*, *law* may mean either a command for persons to obey, or a general expression for a group of physical facts; *same* implies identicality, and also great similarity; *may* and *can*, sometimes signify liberty, and sometimes possibility, &c., &c.

2°. *Fallacia figuræ dictionis.* It frequently happens that *paronymous* words, *i.e.*, those which have a grammatical relation to each other in consequence of their springing from the same root, differ considerably in meaning, but yet in the haste of an argument are assumed to be of similar import. This produces what the old logicians have termed the *fallacia figuræ dictionis*, and is dangerous on account of the many variations which may be, and commonly are, given to a term in the course of a chain of reasoning, without infringing the validity of the conclusion. Thus, it would be perfectly allowable to say, "Wherever a lighted candle maintains great luminosity, the atmosphere is respirable; in this well a lighted candle continues to be very luminous; therefore, here the atmosphere is respirable;" for the expressions "to maintain luminosity" and "to continue luminous" are justly treated as equipollent: but were we to say, "No designing persons are honest; all sculptors design; therefore no sculptor is honest," we should in reality employ four terms; "designing" meaning *scheming* or *plotting*, while "to design" implies the *conception of some idea to be executed by an artist.*

The proper method of combating this fallacy consists in an explanation of the different senses attaching to the paronymous words.

3°. *Fallacia sensus compositi et divisi.* This, which is also termed the fallacy of composition and division, is produced whenever a term is used in one judgment *collectively*, and in the other *distributively*. A simple example is as follows:—

"Five and two are odd and even; seven is five and two; therefore, seven is odd and even." Here "five and two" means in the major premiss, those numbers alluded to distinctly and respectively; in the minor, the same taken together; accordingly, there is a case of *quaternio terminorum.*

Perhaps the most frequent method of employing fallacies of this description, is when a truth which has been separately established concerning many individual notions is sought to be inferred of them all collectively. Thus it is occasionally argued, that because the ordinary alterations of temperature produce comparatively little effect upon the physical configuration of the earth's surface, and because the same thing may be asserted of each of the natural disintegrating and abrading powers, such as tides, rivers, rain, glaciers, &c., therefore the combined operation of all together would not do more, and, consequently, that we must assume some grand cataclysm as the cause of such great changes as may be apparent.

In all cases of probability there is often a tendency to fall into the error now under consideration, and this tendency is in opposite directions. Suppose we are told that it is an even chance whether the disease upon reaching a certain stage will kill the sufferer or not; and, also, that it is an even chance whether the disease will reach that stage; we are apt to conclude that an even chance results of the person dying or not dying; whereas the chances are three to one against his dying. This is rendered evident as follows: the chance of the disease reaching a certain point is one-half of all the possible changes which may supervene; but the chance of dying is only one-half of *these, i.e.*, one-quarter of the possible cases; therefore the chance of not dying is three-quarters, or in the ratio of three to one. Here the probability was over-estimated, but in many instances the reverse is the case: thus, if we were to argue, that because it is improbable that the *whole* of Newton's discoveries were the results of fortunate coincidences, it is, therefore, improbable that *any one* of them was so, we should commit this error.

Archbishop Whately under this head describes what he terms the *thaumatrope* fallacy; this consists in presenting

several incompatible notions to the mind in quick succession, so as to induce the belief that they might exist together. After the Crimean war, for example, a statement was published showing the several objects which the money spent might have separately accomplished. Now, in all probability, many persons on reading the long list, and finding that this, that, and the other thing might have been done, left off with the idea that *all* of these objects together were capable of realisation.

4°. *Fallacia a dicto secundum, &c.* These fallacies arise when we conclude absolutely of a notion what is true of it only under certain circumstances; and when we conclude relatively what is only true when absolute; the latter is sometimes termed *fallacia accidentis.*

Persons occasionally fall into this error when arguing against capital punishment, forming their syllogism thus:—

To return evil for evil is wrong,
Capital punishment is returning evil for evil;
∴ Capital punishment is wrong.

Here the major premiss is only true under certain qualifications; that is to say, a revengeful *animus* is supposed in combination with returning evil for evil; whereas in the minor, the action is considered in the abstract, and without any such attendant circumstance.

Again, uneducated people are greatly astonished upon being told that the earth is nearer to the sun in winter than in summer, for their thoughts immediately run in this fashion; "the nearer we are to a hot body the warmer we must be, and therefore the earth ought to become warmer instead of colder on approaching the sun." The mistake, of course, lies in their ignorance of the fact that we only get warmer upon approaching a hot body *provided that* the rays of heat continue to strike us at the same, or at a more favourable angle.

Fallacies of this nature are very difficult to detect, in consequence of the readiness which exists to lose sight of the limitations which alone render a general law capable of being applied to some particular case. The best method of treatment is to require a rigid proof of both premises, which will always

exhibit whether the inference is legitimated by the circumstances of the case.

The false reasonings which have been described above are the principal fallacies belonging to the genus of *quaternio terminorum;* but there are many various ways of sophistication by means of ambiguity in expression, which, though not syllogistic, are often employed. Such is the practice of asking a question that may be susceptible of various interpretations according to the answer given; *e.g.*, an opponent of free-will might ask, "Am I free to do as I please?" and, being answered in the affirmative, would reply, "Then I am at liberty to kill you and half-a-dozen more if I so please." If answered in the negative, he would at once say, "Then I am controlled by necessity, and am not a free-agent." In this instance the ambiguous word is "free," which in one case is held to mean "free as regards nature;" in the other, "free as regards the laws of society." The student will have no difficulty in forming the corresponding syllogisms.

Perhaps, however, the most celebrated fallacy depending upon the ambiguity of a word, is the sophistical puzzle of Achilles and the tortoise. Its enunciation and solution are given by Mr. Mill as follows:—

"The argument is, let Achilles run ten times as fast as the tortoise, yet if the tortoise has the start, Achilles will never overtake him. For suppose them to be at first separated by an interval of a thousand feet: when Achilles has run these thousand feet, the tortoise will have got on a hundred; when Achilles has run those hundred, the tortoise will have run ten; therefore, Achilles may run for ever without overtaking the tortoise.

"Now, the 'for ever' in the conclusion, means, for any length of time that can be supposed; but in the premises 'ever' does not mean any *length* of time: it means any *number of subdivisions* of time. It means that we may divide a thousand feet by ten, and that quotient again by ten, and so on as often as we please; that there never needs be an end to the subdivisions of the distance, nor, consequently, to those of the time in which it is performed. But an unlimited number of subdivisions may be made of that which is itself limited.

The argument proves no other infinity of duration than may be embraced within five minutes. As long as the five minutes are not expired, what remains of them may be divided by ten, and again by ten, as often as we like, which is perfectly compatible with their being only five minutes altogether. It proves, in short, that to pass through this finite space requires a time which is infinitely divisible, but not an infinite time."

Another example of the same fallacy may be thus given: If at present we look forward into eternity we see that the duration yet to come is infinite; but the same state of things will obtain a hundred years hence, and as two infinite durations must be equal to each other, the futurity then, and the futurity now cannot differ; therefore the hundred years constitute no lapse of time whatever, as otherwise there would be a difference of so much between the periods in question. Thrown into a syllogistic form the argument would stand as follows:—

Two infinite durations are equal to each other,
The present futurity, and the present futurity less a hundred years, are two infinite durations;
∴ The present futurity is equal to the same, less a hundred years.

Here the major premiss involves a contradiction in terms, for it implies that two *incommensurable* things (*i.e.*, two different *infinities*) are *commensurable;* it is, therefore, inadmissible. Or the solution might pass were we to say that the middle term is ambiguous, meaning in the major premiss, "two infinite durations starting from the *same point*," and in the minor, "two infinite durations starting from *different points*."

§ 5. *Material Fallacies: Premiss unduly assumed.*

1°. *A priori fallacies.* We have now to consider those errors which arise from the assumption of a premiss, either without any proof at all, or without such proof as would be considered sufficient by both parties, if they were equally apprised of the questions at issue. And first, of those cases where there is no proof whatever of the assumed premiss.

As an essential preliminary, it must be remarked that there are some truths which we do not attain by any reasoning process,* and which, therefore, are not susceptible of proof. Thus, when a piece of brass engages my attention, I am conscious of some change which takes place in my mind, and this change I call the *sensation of yellow*, applying the name *yellow* to those attributes of the brass which produced the sensation; therefore, when I say, "This brass is yellow," I cannot abstractedly prove the statement, as I am merely asserting a subjective fact, of whose existence I alone can judge, and which is only granted by my opponent in consequence of his being affected by similar sensations. Accordingly, such truths are termed *self-evident*, and must form the foundation of all reasoning.

This consideration is the clue which guides us to the source of the particular class of sophisms at present under investigation. Men, finding that certain of their sensations correspond with outward facts, go further, and imagine that whenever any subjective state of consciousness is ascertained, there must always exist a correlative condition of the objects about which thought is concerned. Thus, Philolaus and the Pythagoreans, imagining that the nature of fire was more incomprehensible than that of earth, and feeling that whatever they could least comprehend impressed their minds with the greatest sensations of awe, concluded that fire in itself was more capable of majesty than earth, and in the disposition of the universe would occupy the most worthy place. Accordingly, they conceived that there existed in the centre of the universe a mass of fire termed the "Altar of Nature," and that, at distances varying with the different degrees of fiery composition, were ranged the heaven containing the fixed stars, the planets, and all other cosmical bodies.

Perhaps the most prevalent class of *à priori* fallacies is that which results from an inspection of the imaginative powers, it being assumed that objective existence is dependent upon

* A practical view. Compare with this the section upon Observation.

the possibility or impossibility of its being conceived by us. Dr. Clarke, for instance, in a correspondence with Bishop Butler, makes use of the following expression, "The *supposing* anything possibly to exist alone, so as not necessarily to include the pre-supposal of some other thing, *proves* demonstrably that that other thing is not necessarily existing; because whatever has necessity of existence cannot possibly, in any conception whatsoever, be supposed away." Here the statement is implied that because we *cannot conceive* it, therefore, no necessary existence can be apart from or independent of any other existence; this, of course, being an arbitrary assumption that the laws of our minds regulate the facts of nature.

Again, one of the most celebrated modern systems of philosophy was based upon this error; viz., that of Descartes, concerning whom Mr. Mill speaks thus:—"His favourite device for arriving at truth, even in regard to outward things, was by looking into his own mind for it. 'Credidi me,' says his celebrated maxim, 'pro regulâ generali sumere posse omne id quod valdè dilucidè et distinctè concipiebam, verum esse:' whatever can be very clearly conceived must certainly exist; that is, as he afterwards explains it, if the idea includes existence. And on this ground he infers that geometrical figures really exist, because they can be distinctly conceived. Whenever existence is 'involved in an idea,' a thing conformable to the idea must really exist—which is as much as to say, whatever the idea contains must have its equivalent in the thing; and what we are not able to leave out of the idea cannot be absent from the reality. This assumption pervades the philosophy not only of Descartes, but of all the thinkers who received their impulse mainly from him, in particular the two most remarkable among them, Spinosa and Leibnitz, from whom the modern German metaphysical philosophy is essentially an emanation."*

Locke, too, founds his proof of the existence of a God upon the considerations, that as (self-evidently) nothing cannot produce any real being, something must have existed from all

* "Logic," book v. chap. iii. § 3.

eternity; and that this something must be a cogitative being, because it is as impossible to conceive that every bare incogitative matter should produce a thinking intelligent being, as that nothing should of itself produce matter. This reasoning hinges upon the supposition that "what is inconceivable is impossible," a proposition which is continually being disproved as knowledge advances, and our means of investigation become greater. In fact, that great truth which is ever present with us—the action of mind upon matter—should of itself suffice to overthrow all reliance upon any *necessary* connection between subjective and objective existences.

An ordinary case of the operation of the above fallacy is to be found in the reception accorded to any account of wonderful events. Take, for example, the case of mesmerism, or spirit-rapping. One person cannot conceive the possibility of the facts being produced by ordinary means, and, *therefore*, assumes that they must be the results of supernatural agency; while another, not being able to imagine that immortal beings would, or that mortals could, give rise to such events, concludes that these cannot have occurred. In each extreme an erroneous inference takes place, founded upon a premiss unduly assumed.

Another duplicate group of errors is based upon the suppositions that nothing can be true unless some reason can be assigned for it, and that everything must be true if there exist no reason against its being so. To the former may be referred the usual objection of "*cui bono?*" which assumes that an objective fact does not exist if its practical uses are not immediately observable. To the latter belong most of the *à priori* demonstrations of physical truths, one of the best known being Duchayla's proof of the composition of forces, which rests upon the axiomatic statement that "the resultant of two forces meeting at a point, must bisect the angle between them." This is said to be self-evident, "*because we can assign no reason* why the resultant should incline to one force rather than to the other." Here, as all *à priori* reasoning is necessarily anterior to experimental knowledge, we cannot be certain but that something may exist in the natural action of two forces upon each other, which shall invariably

incline their resultant to the right or to the left; nor can any reason be assigned for the resultant bisecting the angle, rather than inclining to one of the forces. The first step, therefore, of the proof being unfounded, the remaining portions are untenable; and, indeed, it would appear generally true, that the only valid reasoning with reference to physical facts is such as may be deduced from experiment, *i.e.*, such as is *à posteriori*.

A very ancient example of the fallacy which we have just considered is to be found in the astronomical doctrines of Anaximander, who flourished at the commencement of the sixth century, B.C. He held that the earth was suspended immovably in space, *because** "being equidistant from the containing heaven in every direction, there was no reason why it should move in one direction rather than in another."

There remains but one more species of *à priori* fallacies to which I shall allude, viz., those arguments which rest upon the suppositions that an effect has but one cause, and that causes must resemble their effects. Thus, Plato,† in one of his dialogues, makes Socrates give an account of an investigation into the causes of things, which results in the conclusion that every phenomenon has its own single and separate cause—a substance being red, because a certain abstract "redness" dwells in it; large, because an abstract "magnitude" is present; small, on account of "littleness;" and so on. This opinion pervaded all philosophy until the days of Bacon, who, by his advocacy of experiment, led the way towards the admission that the same effects may be produced by different causes. At the same time, however, it is to be remarked that even Bacon himself was not altogether free from these errors, inasmuch as in his celebrated inquiry concerning the "form," or nature of heat, he assumes that the sensation of heat is always caused by the same set of conditions or attributes, whereas we now know that intense cold (and other causes) will produce a similar effect as far as our feelings are concerned. He also imagines that there must be

* Sir G. C. Lewis's "Astronomy of the Ancients," chap. ii. § 5.
† "Phædo," § 103.

a *resemblance* between causes and effects, for we find him speaking as follows :*—"Heat is a motion of expansion, not uniformly of the whole body together, but in the smaller parts of it; and at the same time checked, repelled, and beaten back, so that the body acquires a motion alternative, perpetually quivering, striving and struggling, and *irritated by repercussion*, whence springs the *fury* of fire and heat." Hence it is that, although very near the mark, he has yet failed to obtain a clear and comprehensive notion of heat, for he says,† "Again, it [that heat is a motion of constituent atoms, not of constituted bodies] is shown in this, that when the air is expanded in a calender glass, without impediment or repulsion, that is to say, uniformably or equably, there is no perceptible heat. Also, when wind escapes from confinement, although it burst forth with the greatest violence, there is no very great heat perceptible, because the motion is of the whole, without a motion alternating in the particles." Here, from the assumption that the *sensation* of heat must always be produced by heat, he concludes the absence of the latter in cases where we know it is really present. The reason, then, of Bacon's failure would appear to be that he confined himself to the investigation of the nature of that set of conditions which are capable of producing the sensation of heat; whereas he should have endeavoured to ascertain the number of different effects which might be produced by the action of heat: "the power of artificially producing an effect," as Mr. Mill says,‡ "implying a previous knowledge of, at least, one of its causes. If we discover the causes of effects, it is generally by having previously discovered the effects of causes."

I have considered these *à priori* fallacies at some length, in consequence of their universal influence, and small liability of detection. The remedy is to deny the self-evidence of the assumed principle, and require a proof.

2°. *Fallacies from pre-conceived opinions.* It often happens that men are content to accept, as established truths, assertions whose only foundations are derived from their

* "Nov. Org.," book ii. Aph. 20. Spedding's Trans. † Ibid.
‡ "Logic," book v. chap. iii. § 7. Compare with preceding remarks.

consonance with some pre-conceived opinion, or from a hasty inspection of the facts involved. And in cases where an intentional piece of sophistry is employed, the most successful plan is to mention the premiss as something wonderful and surprising; the effect of which is that our attention is no longer directed to the question of the proposition's truth or falsity, but rather to the best method of *accounting* for the *fact*.* Thus, the Royal Society were, for a long time, puzzled by King Charles II.'s inquiry, as to the reason why a *dead* fish will not add to the weight of a vessel of water, although a *live* fish will; and it was not until after many vain attempts to discover a solution of this marvel, that the philosophers remembered that there might be a doubt as to whether it existed at all.

Most cases of superstitions may be referred to this head; that is to say, most instances of superstitious belief producing any effect upon the mind. How many reputed supernatural appearances would have been investigated, and their real nature detected, if the prevalent belief that such events were of frequent occurrence, had not precluded the necessary examination! And even to the present day, there are persons to be found in provincial districts, who will attribute any sudden misfortune to the operation of witchcraft, simply because they have always understood that this power was the usual cause of similar events; never deeming it necessary to ascertain the truth of the tradition.

Indeed, there would seem to exist some faculty in the mind which renders us disposed to accept whatever is handed down in the shape of tradition, the more especially if it be of prodigious and marvellous import. Possibly the fact is, that the majority have a great disinclination to exert their mental powers more than is absolutely required for the proximate objects of their pursuits; and, consequently, they regard with disfavour any attempt to disabuse them of erroneous opinions, as such a course would necessarily involve the exertion of accustoming themselves to new methods of belief.

3°. *Fallacies from false analogies.* Analogy is, properly

* Compare Whately's "Logic," book iii. § 14.

speaking, a "resemblance of relations;" and when "we argue from analogy," we assert that two objects which resemble each other in one point, will also resemble each other in another point, which depends in both cases, by a similar relation upon the first. Thus, we conclude that ammonium is a metal, because it resembles other metals in its formation of an amalgam with mercury; that is to say, the relation between the constituents of each amalgam, being precisely similar, we infer that they are severally composed of mercury, in combination with a metal. But were we to infer that sulphur is a metal, because heat vaporises it as well as all metallic substances, we should be employing a false analogy, because the relation of vaporisation does not necessarily determine the presence of a metal in conjunction with heat.

Accordingly, a fallacy of false analogy may be considered to exist wherever from a resemblance in one point is inferred a resemblance in another, without, at the same time, its being shown that there exists a similarity of relations between the two points.

Professor De Morgan notices the following prominent instances of this fallacy* :—"All the makers of systems, who arrange the universe, square the circle, and so forth, not only comfort themselves by thinking of the neglect which Copernicus, and other real discoverers, met with for a time, but sometimes succeed in making followers. These last forget that for every true improvement, which has been for some time unregarded, a thousand absurdities have met that fate permanently. It is not wise to toss up for a chance of being in advance of the age, by taking up at hazard, one of the things which the age passes over. As little will it do to despise the usual track for attaining an object, because (as always happens) there are some who are gifted with energies to make a road for themselves. Dr. Johnson tells a story of a lady who seriously meditated leaving out the classics in her son's education, because she had heard Shakspeare knew little of them. Telford is a standing proof (it is supposed by some) that special training is not essential for an engineer."

* "Formal Logic," p. 276.

In Plato's "Dialogue upon the Immortality of the Soul," Simmias objects that, according to Socrates' account, the soul is a harmony of the body, and that therefore, it will be destroyed when the body is, in the same manner as the harmony of a lyre ceases when the lyre is broken. But Socrates shows the fallacy of this argument, by pointing out that the same relation does not obtain between the soul and body, as between the lyre and its harmony; for, as had been previously granted, the soul exists before the body, and is, therefore, independent of it, while the harmony of any particular lyre cannot exist until the instrument is constructed, and accordingly perishes when it is destroyed.

The records of ancient astronomy abound with examples of fallacious analogies. The Pythagoreans, for instance, are reported by Aristotle, to have conceived that ten was the only perfect number, and, therefore, the number of bodies revolving round the central fire must also be ten. But nine only were visible to them; viz., the sun, the moon, the earth, the five planets, and the sphere of fixed stars; accordingly, they imagined another, which they termed the antichthon, and declared to be invisible from the earth, as it was upon the opposite side to the inhabited portion. In like manner, the distances of the several orbits were assumed to increase constantly, in the ratio of three to one, a calculation which made the sun's distance from the centre 729: this number being both a square and a cube, the sun also was said to be a square and a cube. "Finding that the distances of the planets bore, or seemed to bear to one another, a proportion not varying much from that of the divisions of the monochord, they inferred from it the existence of an inaudible music, that of the spheres: as if the music of a harp had depended solely on the numerical proportions, and not on the material, nor even on the existence of any material—any strings at all. It has been similarly imagined that certain combinations of numbers, which were found to prevail in some natural phenomena, must run through the whole of nature: as that there must be four elements, because there are four possible combinations of hot and cold, wet and dry; that there must be seven planets, because there were seven

metals, and even because there were seven days of the week. Kepler, himself, thought there could be only six planets, because there were only five regular solids."* Nor must it be imagined that these fantasies are confined to the olden times, for I, myself, have heard a clergyman seriously maintain, from the pulpit, that the number seven must be sacred in its nature, because it is composed of three and four; the former representing the Holy Trinity; the latter, man and nature, all of whose attributes and members are regulated by twos and fours.

"Another example is the not uncommon *dictum*, that bodies politic have youth, maturity, old age, and death, like bodies natural—that after a certain duration of prosperity they tend spontaneously to decay. This also, is a false analogy, because the decay of the vital powers in an animated body, can be distinctly traced to the natural progress of those very changes of structure, which, in their earlier stages, constitute its growth to maturity; while in the body politic, the progress of those changes cannot, generally speaking, have any effect but the still further continuance of growth: it is the stoppage of that progress, and the commencement of retrogression, that alone would constitute decay. Bodies politic die, but it is of disease, or violent death: they have no old age."†

Fallacies of false analogy may be shown to be erroneous, by proving that there is no causative connection between the resemblance observed and the resemblance inferred; or, in other words, that it does not necessarily follow that they must always co-exist.

4°. *Fallacies from false generalisations.* Numerous causes exist, which lead us to infer universal propositions where only particular ones are warranted by the facts of the case. Memory itself is an active agent in promoting this error; as, for instance, in the case of predictions being verified, marvellous coincidences, and the like, we only remember those occurrences where the prediction was fulfilled, or where some result followed the coincidence, and entirely forget those of

* Mill's "Logic," book v. chap. v. § 6.
† Mill's "Logic," book v. chap. v. § 6.

the contrary nature. We then enumerate the remembered cases, and conclude that the prophet is a true one, and that the coincidence is an example of cause and effect.

This fallacy often assumes a dilemmatic form, and was in constant use among the ancient Greek logicians, when engaged in their disputative tournaments. A celebrated instance is the following, which endeavours to show, from the argument of necessity, that it is of no use to strive against any occurrence, fortunate or unfortunate.

If I ought to exert myself to effect a certain event, this event either must take place or it must not;

If it must take place, my exertion is superfluous; if it must not, my exertion is of no avail;

∴ On either alternative, my exertion is useless.

Here, in the major premiss, it is assumed that for the event to take place necessarily, and for it not to do so, are all the cases possible. But this enumeration is imperfect, as the event taking place may depend upon my own exertions; and therefore, the alternative member of the premiss should be, "This event must either take place through my own exertions, or through some other cause, or not at all."

Occasionally, the answer to a dilemma is to "retort" it; *i.e.*, to propose one which shall be correlative and reciprocal. The best known of these cases is called the *litigiosus*. Sir William Hamilton's account is as follows:—"It relates to an action between Protagoras, the prince of the sophists, and Euathlus, a young man, his disciple. The disciple had covenanted to give his master a large sum to accomplish him as a legal rhetorician; the one half of the sum was paid down, and the other was to be paid on the day when Euathlus should plead and gain his first cause. But when the scholar, after the due course of preparatory instruction, was not in the same hurry to commence pleader, as the master to obtain the remainder of his fee, Protagoras brought Euathlus into court, and addressed his opponent in the following reasoning:—'Learn, most foolish of young men, that however matters may turn up (whether the decision to-day be in your favour or against you), pay me my demand you

must. For, if the judgment be against you, I shall obtain the fee by decree of the court, and if in your favour, I shall obtain it in terms of the compact, by which it became due on the very day you gained your first cause. You thus must fail, either by judgment or by stipulation.' To this Euathlus rejoined:—'Most sapient of masters, learn from your own argument, that whatever may be the finding of the court, absolved I must be, from any claim by you. For, if the decision be favourable, I pay nothing by the sentence of the judges, but if unfavourable, I pay nothing in virtue of the compact, because, though pleading, I shall not have gained my cause.' 'The judges,' says Gellius, 'unable to find a *ratio decidendi*, adjourned the case to an indefinite day, and ultimately left it undetermined.'"

The "horned" dilemma is also a much-renowned fallacy. It consists of the question, "Have you cast your horns?" to which, if you answer "No," I reply, "Then you have them still:" if you answer "Yes," I reply, "Then you have had horns." The error here is the assumption that you must either have had horns and cast them, or have had them and retained them; whereas, another case is possible, viz., the fact that you have never had them.

Another example is the fallacy of continuous questioning, to which the name of *sorites* is often applied. It is thus employed:—The sophist asks whether a man with so many thousand hairs on his head is bald. You answer, "No;" and are next asked whether if he had one hair less he would be bald. The same reply being given, a further diminution of one hair takes place, and so on, until you are either forced to admit that you cannot distinguish between bald and not-bald, or that they differ by a single hair. The reasoning is based upon the supposition that a man must either be bald or not-bald, whereas he may be both: and this refutation does not involve a contradiction in terms, as at first it would seem to do, for "bald" and "not-bald" being relative terms, may, when their correlatives differ, be both applied to the same object. Of course, an *exact* method of evading the sophism would be to regard "bald" as meaning entire destitution of hair; in which case there would be no absurdity in

maintaining that a single hair constituted the difference between bald and not-bald.

These will serve as a specimen of the fallacies invented by the Greeks for purposes of recreation. We will now consider the practical forms in which false generalisation appears among the ordinary reasoning processes of philosophy and common life.

The *non causa pro causa* is an error of very wide extent, and consists in imagining a causal relation between two facts which happen to occur either at the same time, or within some short interval of one another. Thus, the ancients imagined that anything which apparently moved of itself was animated, since they had observed voluntary motion to be accompanied by life in many cases: accordingly, they assumed that the stars were animated. Here, from observing a coincidence, they inferred a causal relation, and so laid down a general law which, false in itself, was the parent of many kindred errors when applied to scientific speculations. So, too, from the fact that wars or pestilences have happened soon after the appearance of a comet, it has been held that heavenly bodies of like description are the causes, or at least precursors of great calamity. In this case, a sequence was considered as a relation of antecedent and *consequent;* the technical name for such a fallacy being *post hoc, ergo propter hoc*, while the former is called *cum hoc, ergo propter hoc.*

It is not, however, to be supposed that all examples of this fallacy are of such a simple description. Thus, a country is often said to be prosperous *because* it is rich, whereas in fact, it is rich because it is prosperous: or the government and constitution must be praiseworthy, because under them the country has flourished, the truth being that it has flourished *in spite* of them.

The want of sufficient investigation frequently leads to false generalisation: iron, for instance, was supposed to be rusted whenever it came into contact with water; recent experiments have, however, determined that air, and probably carbonic acid, are also necessary to the production of this effect. Oxygen, as is imported by its name, was considered the active principle of all acids, merely because it was a

constituent of such as were then known analytically: the doctrine was but short-lived, owing to the discovery that many acids contained no oxygen whatever. And this will always be the case, where efforts are alone directed to discover the points of similarity between various bodies, instead of the attempt being made to ascertain the properties wherein they differ.

"Experience" has also much to account for as an erroneous guide: no public vehicle had been made to run at more than ten or twelve miles the hour; therefore, to travel quicker by railway could never take place. A certain law has hitherto worked well; therefore, it will never require alteration: the swans that had been seen before the discovery of Australia were white; therefore, there were no black ones. No person had met with birds without wings; consequently, until the *apteryx* was found in New Zealand, the notion obtained that all birds were thus provided; and so on, the love of dogmatising from truths within our observation to facts beyond it, being irresistible.

Of a similar nature is the employment of general propositions as such, which are only the result of a majority of cases: estimates of national character, for instance, when applied to an individual case, cannot give a correct *inference*, although, of course, the conclusion may possibly be true. When I say the Hindoos are Pagans, I mean only that most of them are so; and, therefore, were I to declare that this man is a Pagan because he is a Hindoo, my syllogism would either be invalid, the middle being undistributed, or the major premiss would be unduly assumed.

5°. *Fallacies from a False Estimation of Probabilities.* A premiss which in itself is only probable, is not uncommonly assumed as certain; or, should it be just possible, it is taken as probable. The degrees of probability are also unduly increased in many arguments, more especially where the reasoning takes the form of a sorites or epicheirema. Thus, if we were to argue that since earthquakes are possibly caused by sudden formations of steam within the earth, and since the intrusion of fused rocks and other highly heated matter into cavities filled with water would probably occasion

such bursts of steam, therefore, the probable existence of internal lakes may be inferred, we should vastly over-estimate the chances involved. So, "one of the great fallacies of evidence is the disposition to dwell on the actual possibility of its being false; a possibility which must exist when it is not demonstrative. Counsel can bewilder juries in this way until they almost doubt their own senses. A man is shot, and another man, with a recently discharged pistol in his hand, is found hiding within fifty yards of the spot, and ten minutes of the time. It does not follow that the man so found committed the murder; and cases have happened, in which it has turned out that a person convicted upon evidence as strong as the above, has been afterwards found to be innocent. An astute defender makes these cases his prominent ones; he omits to mention that it is not one in a thousand against whom such evidence exists, except when guilty." *

The chance of deception in such cases must depend, in a great measure, upon the capacity of the parties to decide upon the proper weight to be given to each probability. If numerical values can be assigned to the various statements, the conclusion is merely a matter of arithmetical computation, but it would seldom be feasible to obtain the consent of an opponent to such a course. Accordingly, the best plan is to require that each proposition shall be expressed in one of these forms—"A is more likely than not, to be D," or, "A is less likely than not, to be D:" it is a simple matter then to arrive at a satisfactory result.

6°. *Fallacy of Reasoning in a Circle.* This fallacy arises whenever one of the premises is the same in sense with the conclusion, and it is scarcely necessary to point out that its unfairness consists in the fact of assuming as already proved (*i.e.* as a premiss) the very thing which you are about to prove, viz., the conclusion. An argument might, for example, be maintained in the following manner:—"Light is certainly material, for it adds to the weight of any body which absorbs it, although in so slight a degree as to escape perception by our most exact means of investigation.

* De Morgan's "Formal Logic," pp. 275-6.

And that it does so add to the weight results from the considerations that all matter is ponderable to some extent at least, and that when any substance is absorbed by another, the ponderosity of the former is necessarily added to that of the latter." If this train of reasoning were extended by a judicious introduction of illustrative examples of each statement, with elaborate analyses of the various principles involved, it might very possibly escape the observation of many readers, that to mention in such connection the case of one *substance* being absorbed by another, is, in reality, to assume the conclusion, *i.e.*, that light is material.

7°. *Petitio Principii* is a modification of the foregoing, and occurs when the faulty premiss is "proved from the conclusion, or is such as the persons you are addressing are not likely to know, or to admit, except as an inference from it, as *e.g.*, if any one should infer the authenticity of a certain history, from its recording such and such facts, the reality of which rests on the evidence of that history." *

This fallacy is more dangerous than that of reasoning in a circle, from the circumstance that the premiss merely *depends upon*, and does not *explicitly state* the conclusion; consequently, it often requires a minute and searching investigation to detect the error. Hence we cannot be surprised upon discovering that many philosophers whose acuteness and intellectual power stand almost unrivalled, have yet fallen into the snare of *petitio principii*, or, in other words, have "begged the question" at issue. "Plato, in the "Sophistes," attempts to prove that things may exist which are incorporeal by the argument that justice and wisdom are incorporeal, and justice and wisdom must be something. Here, if by *something* be meant, as Plato did in fact mean, a thing capable of existing in and by itself, and not as a quality of some other thing, he begs the question in asserting that justice and wisdom must be something." †

It has, indeed, been urged that every syllogism is a case of the *petitio principii*, since the truth of the major premiss

* Whately's "Logic," book iii. § 13.
† Mill's "Logic," book v. chap. vii. § 2.

depends upon the truth of the conclusion. Thus, in this argument—

All horses are quadrupedal,
Bucephalus is a horse;
∴ Bucephalus is quadrupedal;—

it is objected that before we can assert *all* horses to be quadrupedal, it must be true that Bucephalus is so. To discuss the question involved would here, however, be out of place; but those students who may wish for any further information upon the subject will find such in the Appendix, Article D.

A common method of expressing the *petitio principii* is to employ words, which, although synonymous, are yet of different etymology and derivation. A happily-chosen example is thus given by Archbishop Whately: "To allow every man an unbounded freedom of speech must always be, on the whole, advantageous to the state; for it is highly conducive to the interests of the community, that each individual should enjoy a liberty perfectly unlimited, of expressing his sentiments."

The remedy for the last-mentioned fallacies consists in cutting down the chains of reasoning as much as possible, so as to bring the erroneous premiss and the conclusion into close juxtaposition, when it will not be a matter of any difficulty to discern their relation and inter-dependence.

§ 6. *Material Fallacies. Ignoratio Elenchi.*

1°. *Argumenta ad hominem, &c.* The passions and prejudices of men having an enormous influence over their reasoning powers, a skilful sophist will often, by appealing to some particular bias, convince his hearers that such and such a proposition is perfectly correct, and then maintain that being so it must be received as universally true. Now, in doing this he has merely proved the conclusion partially, *i.e.*, in so far only as his hearers are concerned; whereas he should have proved it generally, and as applicable to all classes. Accordingly, he is guilty of an ignorance or evasion of the required proof (*elenchus*), this being the distinguish-

ing characteristic of the class of errors at present under examination.

There are three principal heads contained under the first division of this class, viz., the *Argumentum ad hominem*, the *Argumentum ad verecundiam*, and the *Argumentum ad populum*. Of these, the first consists in unfairly appealing to the opinions, &c., of the individual addressed; the second, in similarly addressing the reverence entertained for old institutions and the like; the third, in apparently determining the question by exciting the passions and fancies of the populace. Thus, I might go to one man whom I knew to be a disbeliever in the results of geological science, and compel him to admit that coal could not have required vast ages for its production, by arguing that the world itself had only existed for six thousand years; this would be an appeal *ad hominem*. Again, I might go to another, and succeed in establishing the same conviction, by reminding him that surely he would never think of setting his opinion up against what had been maintained by men of such learning and genius as so and so, and so and so; here I should address my argument *ad verecundiam*. Or, I might carry this point with a mob, by telling them that the contrary opinion was only upheld by those men who were always endeavouring to deceive the poor, and to take the bread out of the labourer's mouth by new-fangled inventions, which would be an *argumentum ad populum*.

2°. *Substituting a Part for the Whole.* When a universal proposition cannot be established, it often gains admittance by the proof of its corresponding particulars. Thus, with regard to the various sciences it is frequently urged that *none* of the principles are trustworthy, *because* there has always been a difference of opinion as to facts and theory between even the most renowned philosophers. Here the assertion is true in a measure, for *some* facts and theories have undoubtedly given rise to continual discussion; but, then, we must not lose sight of the fact that investigators of all parties and shades of opinion are in perfect agreement as regards the *major portion* of the respective sciences. And this form of *ignoratio elenchi* has a still commoner modification, viz., the assumption which persons frequently make, that upon *their own* preconceived

opinions, men of science are at variance, because controversy exists as to other doctrines; this being, not an inference of the whole from a part, but of one part from another. As might be expected from its recent development, the science of geology is greatly exposed to these mistaken notions; and in reference thereto, Sir Roderick Murchison has made the following valuable observations:—"In all the grand leading *data* on which the history of geology is based, we [himself and Sir C. Lyell] are *completely united;* whether it be in recording the regular succession of formations from the oldest to the youngest, the progression from lower to higher types of life, the enormously long periods which must have elapsed in the formation of deposits, and their frequent change into crystalline conditions by that metamorphism which he has so skilfully expounded; or, lastly, in the evidences he has brought together to show that man must have coexisted with some of the great fossil mammalia. On all these subjects I hold the same opinions as himself; and I have ventured to make this explanation because it seems to me essential that the public should not run away with the idea that *because geologists occasionally disagree on points of theory, that there exists among them any divergence of opinion as to the great foundation stones on which their science has been reared.*"

In the refutation of an argument we frequently meet with examples of this fallacy: the objector shows that his opponent is mistaken upon one point, and thence concludes that the whole of his reasoning is unsound even though it may in nowise depend upon the erroneous statement. "Hence the danger of ever advancing more than can be well maintained, since the refutation of *that* will often quash the whole. . . . . Thus, also, a guilty person may often escape by having too much laid to his charge; so he may also, by having too much evidence against him, *i.e.*, some that is not in itself satisfactory. Accordingly, a prisoner may sometimes obtain acquittal by showing that one of the witnesses against him is an infamous informer and spy; though, perhaps, if that part of the evidence had been omitted, the rest would have been sufficient for conviction."*

* Whately's "Logic," book iii. § 18.

There may often be a combination of the *ignoratio elenchi* with other kinds of fallacies. Thus, instead of proving the *impossibility* of space being finite, philosophers are accustomed to prove its *inconceivability;* and the same thing occurs with regard to any limit of duration: both of these errors arising from the *à priori* belief that the conclusion proved, and the conclusion required, were in each case of equivalent import. So, too, if a supposed cause can be shown as sufficient to produce a certain effect, its existence is inferred, when the real question is, have we any grounds to warrant the supposition itself. Until, for example, Torricelli had succeeded in producing the vacuum to which his name is given, men of science were all agreed upon the statement that "Nature abhors a vacuum," a supposition which was sufficient to account for the difficulty they experienced in making a void space. The illustrious Newton himself adopted the opinion that an interstellar ether existed, not on account of those facts which have led modern philosophers to the same belief, such as the variation observable in the course of comets, and similar reasons; but because he conceived that the effects of gravity might be explained by such an assumption. In the same manner he was obliged to suppose various arbitrary properties of different kinds of matter, in order that his preconceived theory of light should be accordant with the respective phenomena of colour; but yet it must not be imagined that hypotheses are not often of very great service in scientific investigations; for when cautiously applied, and only admitted as provisional, until a more extended knowledge is attained, they form a most valuable instrument of reflection and observation. That such is the case will be at once apparent upon a mere mention of the atomic theory, which found chemistry a scattered, disjointed collection of isolated facts, and gathering the members into one organic whole, left it endowed with vitality, self-impulsive, and possessed of unfathomable power.

The fallacy of "shifting ground" should properly be ranked under this head, and occurs whenever a fresh point is raised before the former one is decided. This is also called "beating about the bush;" it chiefly happens in conversational argu-

ments, and some very good examples may be found in the "Dialogues" of Plato. For instance, in the following passage from the "Gorgias" an *ignoratio elenchi* is finely exposed by Socrates; the question being what name should be applied to Gorgias, the famous orator of Leontium :—

Chæ. But now, since he is skilled in a certain art, what can we properly call him?

Pol. Chærephon, there are many arts among men by experience experimentally discovered; for experience causes our life to proceed according to art, but inexperience according to chance. Of each of these, different persons partake of different arts in different manners; but the best of the best; in the number of whom is Gorgias here, who possesses the finest of the arts.

Soc. Polus appears, Gorgias, to be very well prepared for speaking; but he does not do what he promised Chærephon.

Gor. How so, Socrates?

Soc. He does not appear to me to answer the question that was asked.

Gor. Do you, then, if you please, ask him.

Soc. No, but if yourself would be willing to answer me, I would much rather ask you. For it is evident to me that Polus, from what he has said, has studied more what is called rhetoric than conversation.

Gor. Why so, Socrates?

Soc. Because, Polus, when Chærephon asked you in what art Gorgias was skilled, you praised his art as if some one had blamed it, but you did not say what the art itself is.

In all these cases the only plan of arriving at a satisfactory result is to come to a distinct understanding with regard to the question under debate: and if every proposition admitted or proved be closely compared with the conclusion required, it will be found that very little danger exists of sophistry proving successful.

§ 7. *Conclusion.*

Here, then, terminates our investigation of the several fallacies which most frequently occur; and by a careful study of their various natures, together with the import of the rules laid down for their treatment, we shall find ourselves in a great measure secure against the common forms of error at least; but it will easily be understood that much depends

upon the extent of individual ability, for however perfect an instrument may be, it yet requires a directing intelligence in order to perform its work, and the more ably it is guided the better it will act. Logic can offer no *panacea* against the spread of deception.

The preceding analysis has then enabled us, as far as rules go, to discover whether a given argument be fallacious or the reverse. Accordingly, we are now in a position to understand what true reasoning is, since we know what it is *not;* and we may proceed with some certainty to the consideration of the various processes which are employed in the discovery of truth. In speaking of these processes, I of course allude to those operations which form the especial province of Logic, for although the formal laws of thought must be obeyed in every possible case of observation and reflection, yet there are certain actions of the mind in which they are more particularly concerned. These will form the subject of our next chapter.

CHAPTER VI.

OF LOGIC AS PRACTICALLY APPLIED.

§ 1. *Introductory Remarks.*

THE object of all science is the acquisition of truth, a subject which has as yet occupied but little of our attention; indeed, it would have been impossible to have arrived at any accurate results respecting the *laws* of thinking, if we had not abstracted from these the matter upon which they operate. Now, however, that we have obtained, as I trust, clear and accurate notions of the *mode* in which the natural constitution of our minds influences the operation of all thought, we shall be quite prepared to investigate the *results* of such influence, and to ascertain its practical effects. To do this successfully we must continually bear in mind the various principles which have been enounced during our survey of formal Logic: these relate to the three processes of apprehension, judgment, and inference, teaching us—first, that our objects of thought must be either the ideas of individuals or of classes; secondly, that any assertion concerning these ideas must take the form of a quantitative comparison; and, thirdly, that no reasoning is correct which does not conform to the syllogistic rules, which are proximate applications of the inherent mental canon. But the most transcendent product of our researches has been the firm establishment of the fact that the greatest instrument by which the mind works is *system;* it invariably strives to *arrange* the facts which it gathers, and to erect them into some connected structure; the peculiar office of Logic as a science being to secure the symmetrical adjustment of parts which compose the fabric. This truth, I make bold to say, is the indispensable key to a proper understand-

ing of the nature and working of the reflective faculties; it may be seen to underlie each separate step of our inquiries hitherto; and no explanation of the mysteries involved in the mind's search after truth can be complete unless it enters as an essential element.

Thus much premised, it will readily be imagined that unless our researches conform *strictly* to the natural laws of the intellect, we can only arrive at confusion and contradiction, instead of at truth; for, although we must always in some degree be regulated by the inherent forms of thinking, yet in many cases a considerable deviation takes place, in consequence of an imperfect acquaintance with, and analysis of the principles which should be universally prevalent. This it is which occasions the necessity for an *applied* Logic; that is to say, a science which shall point out the proper method of interweaving the laws developed by formal Logic, with the web of facts that constantly come under our notice, in such a manner that we may attain to the most perfect and correct knowledge of them. And hence it will be apparent that in so doing these laws will require various modifications, in order that they may be accommodated to the respective circumstances of the case; for it must not be forgotten that in treating upon the formal aspect of thought no account was taken of the phases into which reflection would fall when concerned with the *truth* and *falsity* of propositions. So, too, with the mathematical sciences; the principles involved are analysed upon a partial consideration only of the facts to which they are ultimately applied. In geometry, for instance, points are regarded as possessing no magnitude, lines as without breadth, circles as perfectly uniform; although for any practical purposes we must always make allowance for the many departures from theoretical supposition, which must invariably occur. And, paradoxical as it may seem, it is this very disregard of actual truth which confers upon mathematics and Logic the rigid exactness attending all their investigations; the reason being, that by removing all disturbing influences, the attention is concentrated upon such points alone as are of vital importance to the laws which regulate the existence of the science.

Accordingly, we shall find that there is not that precise distinction between the several branches of applied Logic which we found to exist in the subjects about which formal Logic is conversant. The operations run, as it were, hand in hand, presenting such an appearance of simultaneity, that it is often a matter of considerable difficulty to ascertain the exact nature of their mutual dependence and relation. They may, however, be grouped under two heads, Observation and Reflection; the first of these being amenable to the laws of conception and judgment; the second, to those of inference; while connecting them is the motive power of classification, concerning which I have so often spoken. At the same time, it will be impossible, within the present limits, to do more than indicate the best method of studying the vast subject of applied Logic; which, comprehending as it does, the generic features of all the sciences existent and to come, has required the combined efforts of the world's greatest philosophers to attain its present development; and which gives such promise of future progress as to warrant our most sanguine anticipations of results which shall excel by far all that has hitherto been accomplished.

§ 2. *Observation.*

The process of observation naturally presents itself before us as having the prior claim upon our attention; for it is evident that it must always precede reflection, as without objects to think about there would be no thought. And here it behoves us to determine more explicitly than heretofore the import which attaches to the phrase "objects of thought;" as otherwise some ambiguity of expression would be likely to occur in consequence of the idea generally attached to the word "object." This, in ordinary parlance, is held to imply some substance or existence which produces an impression upon our minds, but, when used philosophically, may also signify the impression itself. If, for instance, I say, "Heat is a most mysterious thing," I may either mean the *sensation* of heat, or the *cause* of that sensation; and it is with words of this description that confusion commonly arises. Thus, in Mr. Mill's elaborate and masterly "System of Logic," from

which I have often had occasion to quote, there is the following passage: "But from these and similar generalisations countenance and currency have been given to attempts to resolve, not motion into motion, but heat into motion, light into motion, sensation itself into motion;" where "heat" and "light" would appear to mean the outward *causes* of the respective sensations, and not the *sensations* themselves; for otherwise there needs to be no distinction drawn between "heat," "light," and "*sensation;* but yet, a few lines further on, we read, "All I insist upon . . . is, that it shall not be supposed that by proving these things [*i.e.*, "that certain motions in the particles of bodies are among the *conditions* of the production of heat or light"] one step would be made towards a real explanation of heat, light, or sensation. . . . Let it be shown, for instance, that the most complex series of physical causes and effects succeed one another in the eye and in the brain to produce a sensation of colour; . . . still, at the end of these motions, there is something which is not motion, there is a feeling or sensation of colour." Here, indisputably, Mr. Mill is combating the supposition that the *sensation* of heat, light, &c., is motion, a proceeding, however, altogether irrelevant to the question in hand (as at first stated), viz., whether motion is the *cause* (or "among the *conditions*") of such sensations. An example of this nature is the more instructive, as it will be easily supposed that when so acute and profound a philosopher is led into a confusion of *expression* (for one cannot imagine that there is any confusion of *thought*) by the ambiguity above-mentioned, multitudes of inferior writers will continually mistake the point to be proved, and will involve their arguments accordingly.

Now the word "phenomena" would appear to be better adapted than any other for expressing the notion intended to be conveyed by the phrase "objects of thought;" it being seldom used but in a strictly philosophical sense. We shall, therefore, in the first place, ascertain the nature of those phenomena concerning which our thoughts are occupied, having in view the determination between such as are, and such as are not, the subjects of direct observation.

Every phenomenon is either subjective or objective; either

a condition or state of our mind, or a condition of something apart from our mind. Any knowledge that we may possess of the former must obviously be the result of intuition or immediate perception; but as regards the latter, the operation is by no means so simple, even in the most familiar and, apparently, incomplex cases. Thus, when I touch a piece of iron and say, "This iron is hot," the train of thought from which the judgment results is of the following character:—I look in a certain direction, and am immediately impressed with those sensations of sight, which, from prior experience, I have concluded to be always produced by a series of phenomena termed "iron." I extend my hand in the same direction, and receive two sets of sensations, one consisting of "hardness," &c., thus corroborating the evidence of my eyes as to the existence of "iron," and the other reminding me of sensations similar to those antecedently produced by cases of "heat." I, therefore, feel certain that a series of phenomena exists before me, which resembles a large class of other series in its capacity of raising up a particular sensation, known by the name of "heat;" a conviction which I express by saying, "This iron is hot." Here, then, a process which would be commonly called an act of observation, is seen to consist of two steps: first, the perception of certain sensations, and secondly, an inference based upon the existence of these sensations; consequently, the truth of the statement must depend upon the correctness of the reasoning. Nor is this analysis by any means unimportant, for it frequently happens that a supposed, but non-existent, fact is taken for granted, merely because it has been *observed;* whereas the truth is that it was *inferred.* There is, for example, a beautiful experiment in optics, where a revolving wheel is rendered visible by means of flashes of light, so adjusted that the wheel is once illuminated during each revolution; the effect of this being that although the wheel revolves at the rate of several hundred times a minute, it yet appears to be standing perfectly still; and so perfect is the illusion, that even to imagine it as such is almost impossible. The explanation of this is, that the means employed in the experiment produce sensations which are indistinguishable from those produced by a wheel standing perfectly still,

and this latter phenomenon we accordingly infer to be the case; an instance of fallacious *à priori* reasoning, where the supposition that an effect has but one cause is unduly assumed.

Accordingly, we find that the only phenomena which can be the subject of direct observation, and concerning which we may arrive at *truth* by means of direct observation, are subjective; that is to say, the *existence of certain sensations* is the only thing of which we can be sure when the observing faculties are alone employed. At the same time, it would serve no useful end if we were to push this doctrine to its extreme limits, and more especially in a treatise like the present, which cannot enter very minutely into the ultimate processes of thought; suffice it, therefore, to have called the attention of the student to a point so interesting and essential, as by so doing it may be reasonably hoped that he will have been put sufficiently on his guard to prevent any chance of error arising from this cause. In future, then, I shall not care to be rigidly precise when making use of expressions which involve the process of observation; but I shall still hope to be philosophically exact, for, as we formerly saw when treating upon the parallel case of the so-called immediate reasoning compared with syllogistic inference, a preliminary examination and subsequent neglect of some mental operations is by no means incompatible with a correct exposition of logical science.

Assuming, then, that a comparatively loose sense may be attached to the notion of observation, we have next to inquire into the nature of the process as logically required for the purposes of science; and, as science is merely concerned with the acquirement of truth, it follows that the end of logical observation should be the formation of correct conceptions with reference to those phenomena which are the objects of thought.

Now, the first requisite is that our notions should be *clear;* that is to say, that they should be determinedly fixed; and as the method of arriving at general conceptions, or, in other words, the process of abstraction, has already been described as regards its formal aspect, it now remains to introduce the element of material truth. The main feature of the process consists in comparing together a number of individual objects

with a view to ascertain their points of resemblance, and then conceiving a class composed of any number of objects which might happen to possess those points; and this duplicate operation can only be correctly performed by attending to the following considerations. Let us endeavour, for example, to trace the formation of the conception "metals." We meet with certain individual objects, say gold, silver, and tin, and we wish to obtain such a general notion as may enable us to remember the sensations produced equally by each one of them, and by no other thing. We accordingly analyse the complex impression of each individual, *i.e.*, we concentrate our attention successively upon each separate one of the sensations, and note those which were produced indifferently by gold, silver, or tin. Extending our language a little, we may describe ourselves when so doing as observing the attributes which were possessed in common by the three objects, gold, silver, and tin. Suppose us, therefore, to remark that they all possess weight and hardness; we might here pause and give the name of "metal" to the combination of those two attributes, but were we to do so, we should find that such an idea was not complex enough to distinguish gold, silver, and tin from many other objects, such as stone, wood, &c.; that is to say, we should not have formed a *clear* and *distinct* idea of a metal. We, consequently, resort to observation again and again, until we have abstracted such a combination of attributes, that gold, silver, and tin are the only objects which we know to possess it; we can then *clearly* recall the sensations produced by a "metal." This capability, however, would only belong to ourselves, who had performed the above process; and were we to employ the name in communicating with other persons, it would be necessary for us, in the first place, to define exactly what we mean by the term, as otherwise they might attach a different signification to it, and might include the notions of things totally different from gold, silver, and tin. Here, then, we have two sources of obscurity, imperfect abstraction, and imperfect definition; the remedy for the former being renewed observation; for the latter, those rules which were laid down when treating upon definition in the second chapter of this work.

The second requisite for correct conception is that our notions should be *appropriate;* that is to say, that they should have a proper relation to the question in hand. There can, of course, be no general rule laid down as to what this relation must be in every case, for that can only be settled by the specific end which we propose to ourselves; but yet it may be remarked that the attributes observed should all have some distinct reference to the principle of division adopted in the particular science under investigation. Thus, in the example chosen above, our notion of "metal" would include such marks as hardness, weight, ductility, and malleability, if we were occupied with mechanical researches; to these would be added the capability of forming a base by union with oxygen, if chemistry were our object; while the study of physics would necessitate the inclusion of "great conductive powers" among the metallic attributes.

If, therefore, we take care that our conceptions are clear and appropriate, ascertaining at the same time that our senses do not deceive us as to the real existence of the properties observed, we shall so far be in the possession of truth, and our consequent reflections will rest upon a sound basis. This is all that can be done by observation, and as the nature, conditions, and end of this process have now been described, it would appear that nothing further remains to be added: before, however, I quit this portion of my subject, it may be advisable to offer a few remarks upon the *mode* of observing.

We have already seen that, strictly speaking, subjective facts only can be *directly* observed; but that no inaccuracy need result if we admit the application of the process to certain objective phenomena. It is these latter which will now be considered. And, first, we must note that observation may be direct or indirect; that is to say, we may either employ our unaided senses, or we may make use of instruments to assist us. In the former case, the chief truths at which we arrive are those of quality; in the latter, of quantity. Thus, by making use of the eye alone, we can form an approximate notion as regards the height of an object, and this will be nearer to the truth according as our practical experience is greater; but to know it exactly, we must employ some

measure. Here, in one case, we could merely be sure that the object possessed *some* height; in the other, we could tell the exact *amount*. Or again, a ray of light appears to ordinary observation as perfectly homogeneous and white; Saturn, too, is a mere luminous point; but the application of a prism reveals the existence of various colours in the sunbeam, while a telescope discloses the vision of a far-off world encircled with a glittering belt; and with the perfection of the instrument advances, *pari passu*, our powers of observation. In the solar spectrum, for instance, Fraunhofer was just able to ascertain the duplex nature of the line D, but, recently, Mr. Gassiot, with his magnificent spectroscope, has resolved it into at least sixteen distinctly defined lines. And the same thing took place with regard to Saturn; the employment of a higher telescopic power showed that what at first seemed to be but one belt, was in reality two. It will thus be seen that when the capability of *exact* admeasurement by means of instruments is asserted, all that can be strictly understood is our power of fixing definite limits in one direction at least; and hence we gather that the best method of forming correct conceptions is by observing as precisely as possible, both the *nature* and *amount* of the properties wherein bodies resemble or differ from each other. We must, however, bear in mind the fact that although two attributes differ very much in quantity, yet, if they are alike in *quality*, they will produce exactly the same *kind* of sensation, although varying in degree; consequently, we must place them together in the same class. In our example of "metals," gold, silver, and tin all possess the mark of "weight," but in very different quantities, this difference being one of their distinguishing characters as individuals; and, therefore, if we were to meet with some other object, such as lead, and were to recognise in it the existence of the same kind of attributes as those which we abstracted from gold, silver, and tin, to constitute the notion of a metal, we should at once refer it to that class, although each mark might present a totally different appearance as regarded its amount.

Experiment may also be considered as an act of observation; for although usually the result of reflection, yet in itself

it differs not from the ascertainment of attributes or properties by means of an instrument. In the present place, therefore, we shall merely consider it from the latter point of view, and shall defer all inquiry into the motives for its performance until we come to treat upon the processes of which it is a necessary accompaniment. A *clear* notion then can only be obtained from experiment, by closely observing the nature and amount of the difference between the respective state of things before the commencement, and after the termination of the act; while as to what is an *appropriate* notion, must be wholly determined by the particular object for which we performed the experiment. Thus, if I wished to ascertain the mechanical effects of heat upon red glass, I should notice that the latter became *plastic* when very hot; but were I investigating its optical properties, I should confine my attention to the fact that its *colour* had changed from red to green.

And here it may be remarked that Logic can no more make men good observers than she can make them good reasoners, except in so far as the adherence to rules laid down in strict accordance with mental laws will tend to a healthy exercise and invigorating discipline of the intellect. It is a just saying that "practice makes perfect," but all the watering and attendance possible will never produce an oak from a thistle-seed; and so the most that can be done is to cultivate to the best advantage whatever has been originally implanted. Accordingly, the end of observation—*i.e.*, the attainment of correct notions—will be greatly promoted by the *habitual* exercise of the faculty in accordance with the suggestions given above; but it is necessary that a good observer should also possess a retentive memory and wide experience, as otherwise his ideas would soon become confused, or they would not accord so closely with actual truth as to be of much avail for practical purposes.

§ 3. *Reflection.*

1°. *Of Laws and Causes.* As yet our attention has been confined to the ascertainment of what amount of truth may be acquired by the employment of observation alone. We

have found that even when the widest latitude is allowed, the results so obtained are merely a collection of separate ideas, these ideas being composed of various resemblances and differences. But, numerous as such notions may be, they constitute a very small portion indeed of existent truth. We have certainly coasted along the shore, and surveyed its general features; the vast interior, however, still remains unexplored. That is to say, having collected the facts, we must now examine into their connection, and in so doing we shall perceive that the laws of inference are alone adequate to the task: therefore, without a previous knowledge of them, our labours would but terminate in confusion and disappointment.

The bare *existence* of phenomena has hitherto been the subject of our analysis; we must now endeavour to justly appreciate the *modes* in which they exist; and as the order of time is here alluded to, it will at once be seen that a list of these modes may be easily made; in fact, there are but two—*coexistence* and *sequence*, for phenomena must either occur together, or in succession. Which order obtains in any particular case is, of course, determined by observation; the right understanding of such order is the office of reflection.

Now, in our sphere of thought, we cannot but observe that a certain principle of *uniformity* prevails, more or less, in every occurrence which comes under our notice. Thus, a heavy body if unsupported falls to the ground; a pressure, when not sufficiently opposed, is followed by motion in the object pressed; death invariably succeeds the infliction of certain wounds; the explosion of gunpowder is always accompanied by the extrication of heat and light. All these facts must impress themselves strongly upon our attention. But in other cases the uniformity is by no means so general; it is only some men, for instance, who have black hair; it is only occasionally that we meet with natural springs whose waters are more highly heated than the surrounding earth; it is not always that a west wind is accompanied by rain. These considerations lead us to a distinction between uniformities, which we accordingly regard as necessary, or casual; as invariably occurring, or happening, as it were, by chance. The grounds upon which this distinction may be correctly

made will shortly be explained; at present we are concerned simply with the fact as it stands.

The impression produced upon our minds by the regularity with which many phenomena recur is that nature works according to some uniform necessity, this being termed a *law;* and, consequently, we speak of certain uniformities as being *laws of nature.* Thus, we say that for matter to possess weight as one of its attributes is a natural law; that the orderly constitution of nature renders it necessary for water to tend to find its level; that motion unopposed must continue for ever. It is, however, only to truths of this ultimate description that the term "laws of nature" is applied; many uniformities which at first sight might appear of the same description, being in reality *results* of the former. Thus, that the moon should revolve about the earth as a centre, would, from the perfect uniformity of the revolution, seem to be a natural law; but closer investigation shows that the motion takes place in obedience to three separate laws applied under certain circumstances. In fact, we might predict *à priori* such an effect as resulting from given conditions, but we could not predict the conditions themselves antecedently to experience.

And this leads us to a cognate consideration of great importance; the determination of what is implied by the expression "resulting." Here, of course, the cases are limited to uniformities of sequence—that is to say, those phenomena which we always observe to occur in regular succession. The names usually applied to any duplicate set of this description are *cause* and *effect;* reference being made to a law of nature, which must now be explained, viz., the law of universal causation. Some idea of the mode in which we arrive at this law may be thus given: we observe throughout nature that whenever anything occurs there have always existed some antecedent conditions; and we also observe that certain conditions are invariably followed by definite consequents. If I feel unwell I know that some abnormal state of my body has previously supervened; if I thrust my hand into the fire I know that sharp pain will immediately succeed; when rain falls we feel certain that the suspension of water in the air

preceded the storm; or, should we pass a strong current of electricity through a piece of thin platinum wire, we are assured that the latter will speedily become red-hot. Experience of this nature leads us to the conclusion that if anything have a beginning it has also a *cause;* that is to say, some condition, or group of conditions, must have previously existed, in virtue of which existence the phenomenon in question was produced.

But we must not suppose that *all* uniformities of sequence, how universal soever they may be, are cases in which the law of causation operates; for it will have been observed that the name of *cause* is only applied to those conditions *in virtue of whose existence* the effect *necessarily* follows—to those phenomena without which other phenomena would not occur, but which being once posited the other *must* spring into being. Therefore, when the sequence is merely casual, and there is no connection of necessity between the events, we cannot refer them to the law of causation: for example, when summer invariably follows spring; autumn, summer; and winter, autumn; it could not be said that one season was the *cause* of the next, for then the two requisites of cause and effect would be violated; it being possible for a perpetual summer to exist, or for winter to immediately succeed summer without the intervention of autumn, in consequence of some change taking place in the earth's position with regard to the sun, or in the present physical configuration of the earth.

Nor must any mere arbitrary limit be placed upon the signification of "cause;" we must not make a selection from the conditions upon which an event depends. It is true that this is almost invariably done, as when the prick of a needle is said to be the *cause* of the pain which I feel; or when iron is said to be dissolved *because* sulphuric acid is poured on it; or, again, when the metamorphism of certain rocks is said to be produced by the action of fire. In all these cases there is an omission of necessary particulars. Thus, in the first I should not feel pain from the prick unless I were alive, and possessed a certain organisation, &c.; in the second, the iron would not be dissolved if, in addition to the mere presence of the acid, there did not exist a certain attraction between

oxygen and iron, oxide of iron and sulphuric acid; while in the third, some physical properties of matter, such as polarity, &c., are equally essential with heat to the production of the effect. Also, in every case there must necessarily exist a negative condition, besides those which are positive; this being the absence of counteracting causes, that is, those conditions which tend to produce a contrary effect. Thus, in the present state of the solar system, the earth keeps at a certain distance from the sun; but were the latter body and his attendant planets in their common motion through space to enter some resisting medium, the earth, although acted upon by all its former influences, would yet fall into the sun by reason of the new condition preventing the old causes from producing their wonted effects.

Accordingly, the vulgar sense of the word *cause* does not express its philosophical import; and this ambiguity it will be necessary to bear in mind, as, from the convenience attaching to limited notions, it is often expedient for the attainment of the purpose in hand to consider *that* the cause, which really is but a portion of the conditions requisite for the production of the effect. For instance, when heat is said to cause the expansion of a bar of iron, we mean that heat is the condition whose introduction amongst other conditions gives rise to the change in volume; or, in the example given above, the resisting medium would be said to cause the earth's fall into the sun, not because it could produce such an effect when acting alone, but on account of its enabling gravitation to act under less opposition from centrifugal force.

It will now be seen that a *law of nature* is nothing more nor less than the expression of the relation existing between any single cause and its effect. By applying this doctrine to the truths first cited as natural laws, we may obtain a clear notion of its application. That matter possesses weight, then, means that wherever the entity termed matter exists it will possess the attribute of weight; but it may be said that matter would not be matter without possessing weight, and that, therefore, weight would be simultaneous in its existence with matter. This, of course, opens up the question as to all cases of cause and effect, for who can say that the conse-

quent does not commence to exist at the selfsame moment that its conditioning antecedents are complete; so that the argument, if valid, would show that there is no such thing as sequence in any case of causation. Now I am very far from denying the cogency of such reasoning, but this I do say, that for all practical purposes we may safely admit the notion of succession. As, therefore, "weight" is but the attraction subsisting between material bodies, we may assume that were some new matter to be created it would have no weight *until* it attracted, and had been attracted by other matter; this operation taking place by virtue of a natural law that renders its occurrence a matter of necessity. And so with the second and third laws; whenever a gravitating fluid exists there results an equal pressure in all directions, this fact being expressed by the statement that water tends to find its own level; or, lastly, whenever motion exists alone, it continues for ever. In all these cases the antecedents are the causes, the consequents are the effects, and the necessary connections between the respective pairs of phenomena are the laws.

2°. *Of Induction.* When speaking of observation, I had occasion to remark, that the existence of objective facts was a matter of inference based upon our "experience" of subjective phenomena; and again, in the preceding division, we found that the distinction between necessary and casual uniformities, was also originated by the accumulations of observation, *i.e.*, by "experience." What is the meaning of this phrase must now, therefore, be discussed.

We have just synonymised "experience" by the expression "accumulation of observations;" but when we say that a certain proposition is warranted by experience, we do not mean that our inference rests upon the whole mass of observations which we have ever made, but that a consideration of such observations as relate to the fact in question, has disposed us to infer, as a general truth, the uniformity which constitutes the judgment. That is to say, by reflecting upon certain separate observations, we are induced to believe in the existence of some law. The operation of the mind by which this result is produced, has been named Induction, and may be defined as the process of assigning causes for effects.

Now, as it is by induction that we arrive at laws and causes, which, as shown above, constitute by far the major portion of existent truth, it follows that in an exposition of applied Logic this operation of the mind must occupy the most important position. And, accordingly, it will be advisable to treat as fully as our limits of space will allow, upon the nature and method of correct induction; or, in other words, upon the mental laws which impel us to generalise from experience, and upon the quantity and quality of that experience, which these laws render necessary for the establishment of a correct inference.

Let us, then, in the first place, retrace the steps by which we have arrived at any proposition, and endeavour to ascertain upon what fundamental ground they all rest. Suppose we take this judgment, "The earth is a globe;" the question then comes, what are the premises from which such a conclusion was derived? These we know to be "every body which in certain positions would cast such and such a shadow upon the moon, and which could be circumnavigated, &c., is a globe" (U) for the major, and "the earth possesses these attributes" for a minor; and as the latter is the direct product of observation (loosely), it remains to be considered how the former was obtained—that is to say, we must next examine our grounds for stating that *all* globes possess the properties in question. This judgment cannot, of course, be the direct product of observation, for even had we been able to examine every globe at present existing, the proposition directly resulting would not be equivalent to the one above stated, which, being universal, must apply to all globes which have ever existed, or will exist henceforth, in addition to those of present entity. It must, consequently, depend upon reflection, *i.e.*, upon a process of reasoning from observed facts; and as we have seen in formal Logic, that all reasoning whatever may be reduced to syllogisms, it results that the judgment, "all globes possess such and such properties," is a conclusion drawn from previously established premises. Of these Observation gives one, viz., "This, that, and the other globe, have been found to possess the attributes above mentioned;" and, therefore, since the syllogism is valid, the other

must be to this effect, "Whatever may be predicated of this, that, and the other globe, may be predicated of *all* globes;" which means, "Whatever attributes are found to accompany this, that, and the other globe, will be found to equally accompany every other globe." Pursuing a similar course, we next arrive at the following syllogism:—

A case of a certain particular uniformity is a case of the corresponding general uniformity,

The case of this, that, and the other globe being found to possess the attributes in question, is such a case of particular uniformity;

∴ The case of this, that, and the other globe being found to possess certain attributes, is a case of *all* globes being similarly marked.

Now beyond this we cannot go; that is to say, we cannot assign any premises which would necessitate as a conclusion the last-mentioned major-premiss. Accordingly, for all purposes of Logic, we must assume the principle thus stated to be a fundamental law of the mind, by which, from ascertaining one truth, we are compelled to believe another. Its enunciation in the above syllogism is manifestly of a very partial character, as a due comprehension of its import would necessitate a complete explication of the phrase, "a *certain* particular uniformity;" but this is the province of inductive *method*, and is foreign to our immediate purpose, viz., the treatment of inductive *elements*. To firmly establish these, we must next show that the law at which we have just arrived, is really of the nature claimed for it, *i.e.*, fundamental. At the same time, it will not be necessary to proceed any further with an investigation of the mind's ultimate constitution, as to do this would be to intrench upon the domain of metaphysics. But we must rather endeavour to show, that all other principles of reasoning, or axioms, are merely differentiations of the foregoing law. And as so wide a subject could not be entirely discussed in our limited space, it will be sufficient if we confine our attention to the axiomatic "law of causation," and to any one of the mathematical principles; say, "if equals be added to equals, the wholes are equal."

We have already taken occasion to remark that the first of

these axioms is the result of experience,—that it is our observation of *some* cases of antecedence which induces us to believe that *all* events are the effects of causes. But unless there existed some necessary mental law to legitimatize this inference, we should obviously be unable to rely upon its correctness, as then the only conclusion that could possibly be trustworthy, would be that resulting from an inductive syllogism of the kind mentioned in Formal Logic; in other words, we should be unable to proceed beyond the limits of our actual experience. Consequently, our observations of various instances of cause and effect require the aid of the inductive law before we can deduce any such general statement as that under consideration, and which is often termed "the assertion of nature's uniformity."

The second axiom, although usually considered fundamental, is, strictly speaking, of more complex derivation than the law of causation; for the latter is but one step removed from the inductive principle, while the former is separated by two syllogisms. These may be thus expressed:—

1°. Certain particular uniformities legitimatize the inference of the corresponding general uniformities,
Some cases of equal magnitudes being the same number of coincident magnitudes, constitute the required particular uniformity;
∴ It is true that "all equal magnitudes are all coincident magnitudes."

2°. All equal magnitudes are coincident (U),
All sums of equals are coincident;
∴ All sums of equals are equal.

I have stated the second argument as a simple syllogism, although it would be possible to show that it is of an epicheirematic nature, the minor premiss being a conclusion based upon the major. But this matters not in the present place, where we are only concerned with proving that the canon, "if equals be added to equals, the wholes are equal;" or, as otherwise expressed, "the sums of equals are equal," is dependent for its adoption upon the inductive law, and has *per se* no *locus standi*. An inspection of the above reasoning will show that we have effected our purpose, and that the

fundamental grounds of the mathematical axioms are observation conjoined with reflection; the knowledge acquired by experience being developed and increased by the laws which regulate our minds.*

It will be remembered that when treating upon syllogistic inference, we found the fundamental law of that process to be *directly* inapplicable to many forms of reasoning, insomuch that for practical purposes it was developed into a series of proximate rules, which were sufficient to test the validity of all arguments, without our being at the trouble of effecting a reduction to syllogisms of the first figure. The same thing occurs in Applied Logic. We must differentiate the law of induction to such an extent, that the proximate canons thus obtained may enable us to judge correctly as to the truth of the propositions at which we arrive, and may render any reference to original principles unnecessary. But since such a differentiation can only be accomplished by completely appreciating the meaning of the inductive law; it follows that the doctrine of inductive *method* will next claim our attention.

Now, the truths at which we arrive by means of induction, are of two kinds: either the statement of general laws, *i.e.*, an assertion of natural uniformities, without any exact discrimination of cause and effect, such as mathematical axioms, &c.; or the knowledge of special laws, which consists in the assignment of definite causes for definite effects, and *vice versâ*, as, for instance, the truths of astronomy or chemistry. And, first, we will inquire as to what kind of experience warrants us in concluding the latter class of truths.

The cause of any effect is, as already stated, the whole of the conditions which unite in producing it; but this definition being too wide for my present purpose, I shall in the following remarks understand by a *cause* "that circumstance which produces some definite change in a set of antecedent conditions:" thus, a bell while sounding remains in exactly the same state as when it was silent, with the exception that its particles are vibrating: this vibration, then, is termed the

* Some additional exposition of this subject will be found in Appendix D.

cause of the sound. So much being premised, I shall now investigate the mode in which we may determine the cause of any phenomenon.

It will of course be evident, that the cause must exist amongst the conditions which compose the phenomenon in its totality; for otherwise, there would not be that connection of necessity which we have seen is essential in every case of a sequence obeying a law. If, therefore, we have two or more instances of the effect which differ from each other in some things, but all agree in certain conditions, these latter are the only things which exist in every instance of the effect, and, accordingly, in them the cause must be sought. We thus obtain the canon of Agreement, which runs as follows:—

1°. The cause will be found among the circumstances in which two or more instances of the effect agree.

Or,

A uniformity which is observed in two or more instances, may be considered as invariable and necessary.

If, for example, we found that gold and silver both conducted heat, we might say that the cause of such a power was included in the possession of metallic attributes, since that would be the sole circumstance in which the instances agreed; or, in accordance with the above variation of the canon, it would be allowable to hold that every metal is capable of conducting heat. We can, however, only infer *absolute* laws, whether the observed effects be relative or absolute; thus, from gold and silver being heavier than water, we cannot conclude that all metals are so, as the phenomenon investigated was not precisely the same in each case, *i.e.*, the two metals differed in the amount by which they were heavier than water. But since they definitely agreed in possessing weight, we may affirm that property of all metals; indeed, it forms one of the purely metallic attributes.

The information acquired by means of the above canon is seldom satisfactory, as we are only able to ascertain the precise cause in those very rare cases where the phenomena agree but in *one* point; so that although truth is acquired, yet it is so vague and indefinite as to be oftentimes prac-

tically worthless. In the example just given, all that we can be sure of is, that the power of conducting heat is in some manner connected with the possession of metallic attributes. If, therefore, we would arrive at a clearer notion of causes, we must seek for some method of singling out the desired conditions from among the set which have been presented to us by the canon of agreement.

Now, as an effect necessarily follows from its cause, except where there is a counteracting cause (which would be a new condition), we may conclude, that when, of two cases, one contains the phenomenon under investigation, and the other does not, the cause is not to be sought among the conditions common to both. If, therefore, we observe a case which does not exhibit the phenomenon, but all of whose conditions are contained in the set pointed out by the canon of agreement, we shall be enabled to eliminate these conditions from the number among which the cause is to be found, and thus our limits of search will be much narrowed. A sufficient repetition of this process will eventually point out with definition and certainty the law which we are endeavouring to discover; and thus it may be seen that in this we possess a method of complete efficacy, in all cases susceptible of its application. The canon which regulates the operation, and which is termed the canon of Difference, may be enunciated in the following manner:—

2°. The cause will be found among the circumstances in which an instance, composed of a portion of the conditions set apart by the canon of agreement, but not containing the effect, differs from an instance which is composed of all such conditions.

The example chosen for exhibiting the method of agreement is not adapted to illustrate that of difference, for we are unable to select any body which is totally destitute of conductive powers as regards heat; we must consequently make use of some other instance, and leave this to be dealt with hereafter. Suppose we wished to discover the conditions upon which our hearing the sound of a bell depends: we should learn by the method of agreement that all bells, however they might differ in shape, size, tone, &c., yet, when sounding,

agreed in vibrating and in being placed in the atmosphere. Next, we should endeavour to obtain an instance of a bell being struck, and thus thrown into vibration, but under different circumstances, which might result in the sound being no longer heard. This would be effected by striking the bell in the exhausted receiver of an air-pump, when we should be unable to hear any sound; and the condition in which the instances differed, *i.e.*, the presence of an atmosphere, would consequently be the cause of sound being audible.

We have just seen, however, that the method of difference is always inapplicable when no instance of the phenomenon's non-occurrence can be obtained; a circumstance which would be a great hindrance towards the acquirement of truth, were we unable to find any remedy. But this is not impossible, for although the canon of difference is much more powerful than that of agreement, yet it is similarly restricted, as, by its means, we can only discover absolute laws, without any reference to quantity. Accordingly, we must now endeavour to obtain some knowledge of the means whereby the latter object may be accomplished.

Among the uniformities of invariable sequence which come within our observation, we cannot fail to remark the existence in most cases of a certain ratio between cause and effect; between antecedent and consequent. Thus, a small dose of arsenic produces no visible effect upon a man's constitution; a larger dose makes him ill; and a still greater quantity kills him; while beyond this limit no extension of its deadly effect can occur. Or, in blasting rocks, the work done is altogether dependent upon the weight of gunpowder used; assuming, of course, that the *modus operandi* remains the same. We are, consequently, led to the conclusion that the effect is always directly proportional to the cause, and that a variation in one is attendant on, or followed by, a corresponding variation in the other. But in one of the examples mentioned above, this law does not appear at first sight to be universally true, for we have said that however large the quantity of arsenic may be, it can do no more than produce death; and this leads us to the consideration that, for practical purposes, apparent limits are often assigned to the law

in question, a cause being still regarded as the same with reference to the effect, although some condition has disappeared. In the case alluded to, it is evident that the complete antecedent of death is composed of the poison capable of acting upon some organism, together with the organism itself in a *state of life;* but it is equally evident that when death has supervened, the conditions existing are such as not to be capable of producing a similar effect, for the object to be destroyed no longer exists. The law is, therefore, seen to be universal, when we adopt the strict signification of "cause" as formerly explained; but at present we may safely assign those limits which are rendered necessary by our immediate apprehension of "invariable sequence."

The canon then of Proportional Variation runs thus:—

3°. Whenever a phenomenon varies proportionately to the variation of some condition, there exists a uniformity of necessary sequence between them.

The employment of this doctrine will enable us to arrive at truths which would otherwise be inaccessible. Take, for instance, the determination of the properties which cause metals to conduct heat. We find that no two possess equal conductive powers, and, also, that no two possess similar molecular constitution; in like manner we ascertain that any variation in the arrangement of the particles in a single metal occasions a corresponding variation of its conductive power; but as our means of observation do not at present enable us to assign any distinct ratio between the variations of each separate mode of constitution, and the induced variations of conductivity, we can only conclude that some uniformity of dependence exists, without attempting to fix its precise law. I have purposely chosen an example of this extreme nature, as by it is shown that the canons of induction will at all times suffice to assure us of the right path to pursue, even in cases where the imperfect state of science precludes our attaining any immediate proximity to ultimate truth.

We have now discussed the three principal canons of induction; there are, however, various practical corollaries and rules which spring from them, and as it would be impossible to consider each of these separately in a treatise like the

present, I think it best to proceed at once to the investigation of the other processes employed in the attainment of truth, and then to give an account of some scientific discoveries which will exhibit in a concrete form the development and application of such doctrines as we have examined.

3°. *Of Deduction, Hypothesis, and Verification.* By *induction* we are enabled to arrive at general truths. When these are employed for the ascertainment of any particular truth not previously established we are said to *deduce.* Thus, induction has taught us that all beings which possess the attributes of humanity are mortal; therefore, when a fresh nation is discovered in Central Africa, we may with certainty predict that they are subject to death. Or, from the laws which have been found to regulate the respective motions of the bodies forming the solar system, astronomers can accurately foretell eclipses and other results of the changes that continually take place in the relative positions of the sun and its attendant planets. These judgments are the product of deduction based upon prior induction, and it is, therefore, commonly maintained that the sole and ultimate foundation for all our knowledge of truth is experience, *i.e.*, our observation of particular facts. This view, however, we have shown to be but partially correct, as the primary operation to which we traced the process of induction, consisted of a deduction from observation referred to a general principle—of a syllogism, in fact, and, as such, amenable to the laws of mediate inference. Formal Logic, therefore, is the ultimate judge of all the mental operations with which thought is concerned; and deduction is the first step made in our search after truth. Consequently, the title of the present division of Reflection must be held to refer to a secondary and derivative process of deduction, employed for the purpose of utilising the laws determined by the original *deductive* operation which, on account of its strongly marked and distinguishing features, has received the name of Induction.

In all scientific inquiries it is seldom found that single causes are in operation; but as the inductive method is better adapted for the ascertainment of individual than of general laws, it usually makes us alone conversant with the relation

subsisting between solitary cases of antecedents and consequents. Here, then, we have the special province of deduction pointed out, viz., the determining of the effects necessarily resulting from a combination of causes. And as this is done by a series of syllogistic reasonings, it will not require analysis in the present place, as we have already considered these at full length in the chapter upon syllogisms. I may, however, remark that the finest examples of the deductive method will be found in the mathematical sciences, such as geometry and algebra, where the vast body of general truths are all derived from a proper union of a few simple laws.

I have said that by induction we usually arrive at individual laws, *i.e.*, at laws which are applicable to single or to few phenomena. By this I would be understood to mean, that the laws thus acquired will, in general, merely suffice to explain the sequence in the cases under direct consideration, or in cases essentially similar, being quite unserviceable when we attempt to extend their sphere. Thus, the phenomena of falling bodies led at first to the inference that it was the *nature* of most terrestrial matter to move downwards; and a consideration of the planetary motions resulted in the conclusion that orbits were circular, because of the perfection supposed to inhere in that species of curve. And even when more correct notions prevailed, laws were for long entertained, which assumed different sequences of causation as existing between celestial and terrestrial motions, it being reserved for Sir Isaac Newton to point out by a process of deduction, that the one law of gravitation was the regulating principle of the solar system, extending its influence from the determination of the cosmical cycles, to the least important of the movements taking place upon the earth's surface.

It is not, however, always possible at the first blush to obtain such laws by induction, as may suffice when developed by the deductive method, for the full appreciation of the phenomena under investigation. In such cases the resort of the philosopher is hypothesis, which, when properly employed, will often suggest those observations that are capable of affording the grounds required by induction; but as regards the formation of hypotheses, all rules are of little avail, for

success must entirely depend upon that natural sagacity, the possession of which is in a great measure the characteristic of genius. At the same time, it is quite possible to indicate the manner in which a hypothesis should be treated, and to point out the purposes it will best serve.

A hypothesis, then, is the supposition of some law which shall serve to explain such sequences as have become the objects of observation. It is, therefore, employed when the cases in question are incapable of the particular collation required by the inductive canons, or their corollaries; that is to say, when the facts cannot of themselves lead to any determined truth; and when once the hypothesis has been framed it should be used deductively; first, with a view to ascertain if the results thence arising correspond with the actual instances observed; and in the next place, to infer the existence of new phenomena, which may then be sought for, and which, if discovered, will render probable the truth of the supposition. This duplicate process is termed verification, but, as just described, cannot be considered complete; the hypothesis being spoken of, as thereby shown to be "probably," not "certainly," true. In many cases, however, an extension of verification may amount to a perfect induction, for if we first prove that the supposed law is of such a nature as to account for the phenomena already observed, and to predict the occurrence of fresh examples; and, then, in addition, show that no other supposition could offer a similar explanation, we shall satisfy the requirements of the canons of agreement and difference, thus establishing the hypothesis as a true law.

It will also be seen that in verification we have a most important adjunct of deduction, for when the latter process has, from the results of induction, arranged a system of laws, we may test the accuracy of these by employing them to explain observed phenomena, and to foretell facts that yet remain to be discovered; and if in this manner we are led to satisfactory conclusions, we shall be enabled to strengthen the primary induction by means of the additional evidence thus obtained. Experiment is perhaps the most common method of verification, and deals exclusively with the prediction of sequences; in fact, every operation of practical life

is an experiment by which we confirm afresh the laws deduced by the various sciences. Our ships and buildings are all constructed in accordance with the principles of mechanics; the art of agriculture is successful proportionately as it conforms to chemical laws; the safety of every sailor depends upon a special application of mathematics; and thus we continually become more and more convinced of our ability to attain truth by means of a strict adherence to those mental laws which it is the office of Logic to discover and explain.

4°. *Of Analogy.* The framing of any hypothesis is never a work of chance, *i.e.*, a mere guess, in the strictest sense of the word, but is usually suggested by some circumstances of the observed phenomenon. Of these circumstances, the only one which it will be necessary to mention here, is analogy, which, it will be borne in mind, has already required our attention, when we were discussing the subject of fallacies. It was then described as the similarity of relations, and arguments both false and true were noticed as being founded thereupon. We must not, however, suppose that complete certainty may be attained by analogical reasoning; as at the best, one can only infer a very strong degree of probability for the law deduced; this being treated hypothetically, *i.e.*, as a *provisional* principle, until fully verified, when it of course assumes the position of an established truth. It will, therefore, be obvious, that the cogency of any argument from analogy must depend altogether upon the special features of the case; and, accordingly, I shall not attempt to give an exposition of the various analogical methods. The student may, however, gain a very good idea of analogy in general, by carefully considering the following *résumé* of a celebrated problem, viz., whether the planets are inhabited.

In the first place, it is requisite that we should be put in possession of a certain number of facts, upon the basis of which we may found our argument. And, for reasons which will shortly appear, these facts should consist of similarities observed to exist between the earth and the other planets. Accordingly, a judicious use of the telescope has enabled us to accumulate the truths which follow. We find that Mercury,

Venus, and Mars, are each provided with an atmosphere; and so distinctly is this visible, that we can clearly perceive the morning and evening twilight on Venus; we find, too, that clouds exist in these atmospheres, thus showing the existence of meteorological phenomena, such as rain, hail, snow, winds, &c., upon the respective planets. Again, it is ascertained that Mercury, Venus, and Mars revolve upon their axes, giving rise to the regular production of night and day, the respective lengths of these differing only by a few minutes from that which obtains upon the earth; and, as the axis of Mars is inclined to the plane of his orbit at an angle very similar to the obliquity of the terrestrial ecliptic, it follows that as far as the sun is concerned, the seasons in both planets do not vary to any great extent, while very good reasons exist for supposing the same thing to occur in Mercury and Venus also. Nor does much variety obtain in the supply of light and heat to the four bodies of which we are speaking, whether reference be made to its uniformity or intensity; and, as regards the effect of gravity, it is found that the weights of bodies upon the surface of Venus are very similar to those upon the earth, and that weights upon Mercury and Mars are about half as heavy. Lastly, the existence of continents and seas has been observed upon Mars; his polar regions being eternally covered with snow, the limits of which extend in winter and contract in summer.

Having thus found that certain similarities exist between the earth and its neighbouring planet, we must, in the next place, ascertain what bearing these conditions have upon the phenomena of life. Nor does this require a lengthened investigation, for it will be immediately apparent, that on the earth all life is exactly adapted to, and depends upon, such physical circumstances as the existence of light, heat, air, water, night, day, the succession of the seasons, the surface configuration of land and sea, &c., &c. Now, in their relation to life such as ours, the physical conditions of Mercury, Venus, and Mars, may be considered as identical with those of the earth, and, accordingly, we form the following syllogism based upon analogy, or, in other words, upon a similarity of relations :—

Terrestrial phenomena are accompanied by life (A),
Terrestrial phenomena are the phenomena of Mercury, Venus, and Mars (U);
∴ The phenomena of Mercury, Venus, and Mars, are accompanied by life (A).

If the premises are here granted, the argument is perfectly true, for A U A is a valid mood, and the proper method of refuting the syllogism would be to show the falsity of the minor premiss, which asserts, that as far as the present argument is concerned, the physical phenomena of Mars, Venus, and Mercury are the same as those of the earth.

With reference to Jupiter, Saturn, Uranus, and Neptune, the argument is of less force, as although they possess atmospheres, alternations of day, night, and the seasons, together with water, &c., yet a consideration of their bulk, and other reflections, show that if life does exist upon them, it must differ considerably from terrestrial being: at the same time, it may be proved that there need be no greater variation between the life upon those planets and that upon the earth, than exists between the inhabitants of our torrid and frigid zones. Accordingly, the analogical relation is much weaker, thus casting greater doubt upon the admissibility of the minor premiss.

5°. *Of Chance and Probability.* In the preceding remarks occasion has been taken to introduce the subject of probability; and as absolute certainty is of very rare occurrence in practice, it would not be advisable to close this notice of the reflective processes, without adding a few words upon the amount of belief which may be attached to certain judgments.

This leads us to consider a certain restriction which attends the application of the canon of agreement. Its enunciation, it will be remembered, is as follows:—"A uniformity which is observed in two or more instances, may be considered as invariable and necessary;" this referring to a law of causation existing between the common antecedent and consequent of the instances in question. Now it is evident that, for anything we can tell to the contrary, it may be necessary for the *whole* of such antecedent to exist before the phenomenon can be produced; and therefore, at the best, we can only generalize

as to cases precisely similar in every respect to the observed instances. The law thus induced is termed an empirical law, and is of no use for the explanation of phenomena. But then again, it may happen that an effect is capable of being produced by a variety of causes; that is to say, that the common conditions of the instances may co-operate successively with the respective points of difference in giving rise to the same effect, assuming, of course, that we know of no connection between the various instances, all of them being equally independent. In such a case the effect would be termed the result of chance, as distinguished from law; this meaning that we see no reason why the common conditions should be joined to any particular antecedent, or why, if so joined, the phenomenon should occur.

It, therefore, becomes a matter of some interest to discover under what circumstances we are entitled to infer a *causal* instead of a *casual* uniformity, when the canon of agreement is alone used, and when, consequently, we are ignorant of any relation subsisting between the instances except such as are by this means discovered. These circumstances are usually determined in the following manner:—

Suppose a series of instances among which we know none of the causes in operation, nor any necessary connection whatever; as for instance, the case of a box containing balls similar in every respect but colour, these being drawn out separately by a person blindfolded. The question comes as to what probability there is for any one colour to be drawn rather than another. Now the supposition being that any one ball is as likely to be drawn as any other, it follows that if there were only two, black and white, the chances would be equal; and so, in like manner, would it be if there were two of each colour, or three, or four, or, in fact, any number. But suppose there were two white to one black, then it is evident that of all the drawings possible, two would be in favour of white, and only one in favour of black, so that the "chances" are two to one against black; and in general it will be found that, as far as mere casualty is concerned, the probability of any event occurring may be measured by the proportion of the number of cases in favour of such event to the total number

possible; thus, in the first of our examples the probability of white was one-half, or one out of two; in the second it was two-thirds, or two out of three.

By similar investigations mathematicians have determined that the chance against any particular casual event *recurring* a given number of times in succession, is as the number of possible events raised to a corresponding power to unity. Thus, four to one are the odds that heads will not be thrown twice in succession when a coin is tossed; nine to one that heads will not occur three times successively, and so on. Also it has been shown that the chance of an event already observed again occurring may be represented by a fraction whose numerator is composed of the instances observed, increased by one, and whose denominator is the same number increased by two; the chance against recurrence being that fraction, which, together with the chance for, would amount to unity. If, for example, I knew nothing of astronomy, and were to observe a comet appear for six successive nights in a certain portion of the sky, I might reasonably conclude that the chances for the phenomenon being again apparent on the next night were as seven-eighths to one-eighth, *i.e.*, as seven to one.

Thus it will be seen that every increase in the number of times of observing the uniformity under similar conditions lends a vast amount of additional weight to the belief that there is some law concerned, and that the phenomenon is not a product of chance; accordingly, it is considered generally requisite that before an empirical law can be laid down as such there must have been a sufficient number of instances observed to have eliminated chance; that is to say, the uniformity must have occurred a greater number of times than can be accounted for by the operation of chance.

The importance of these considerations will be at once evident, when we reflect that the law of causation and all axiomatic principles are the products of the canon of agreement alone, and are, so far, but empirical laws. As, however, their limits of space and time comprehend all that we, as human beings, are concerned with, we may act upon them with a perfect assurance of their certitude.

6°. *Examples of Reflection. a. The Discovery of Neptune.* I shall take for my first concrete illustration of the reflective process that most stupendous achievement of modern astronomy, the discovery of the planet Neptune, which, presenting as it does one of the completest triumphs of the human intellect, is pre-eminently calculated to display the vast accession of power which original sagacity acquires by the proper development of the reasoning faculties.

The process of verification first led to the above-mentioned discovery, and in the following manner. The Newtonian law of gravity, together with the laws of motion, had been found sufficient for the explanation and prediction of planetary movements until, in 1781, Uranus was discovered by Sir W. Herschel. This afforded a fresh test of those laws, and astronomers were not slow in availing themselves of the opportunity; for not only did they compute tables, and construct ephemerides by which the future places of Uranus might be predicted, but they also calculated the positions which it had occupied in past times, and so were enabled to identify it with a supposed fixed star that had previously been observed at various periods by Flamsteed, Bradley, Mayer, and Lemonnier. At the same time, however, it was found that the planet had not occupied the *exact* positions which were deduced from the above-mentioned laws, as its observed places deviated sensibly from the calculated ones; it, therefore, became a matter of importance to ascertain the cause of such deviations; and for this there were two hypotheses open—either the deviations were caused by chance, such as errors of observation, or by the operation of some definite and regular law. Accordingly, it was not until about 1840 that a sufficient number of observations had been accumulated so as to eliminate chance, and then the facts stood as follows. The planet was known to move in obedience to three causes—the laws of motion, the attraction of the sun, and the perturbations induced by the proximity of Jupiter and Saturn; but a deduction from these failed to explain the whole of Uranus's movements, for from 1795 to 1822 the observed places continued, year by year to be in advance of those calculated, while from 1822 to 1830-1 a regression took place until the

tabular and observed positions agreed; and this regression uniformly continued in the years succeeding 1830-1, so that the hypothesis of some regular disturbing cause was the only one tenable, chance being eliminated, and the planetary deviations being too small to cast any doubt upon the validity of the gravitative and dynamical laws. At this point it was that Messrs. Le Verrier and Adams took up the question simultaneously, each, strangely enough, being in complete ignorance of the other's investigations; and their first resort was to analogy; for, knowing that the irregularities in the orbital movements of other planets were referable to the perturbing effects of mutual attraction, they concluded that the same thing obtained with regard to Uranus; that is to say, they inferred that all those disturbances which could not be accounted for by the influence of Jupiter and Saturn were caused by some planet hitherto unknown. But this was by no means sufficient, as mathematical considerations proved that any one of an infinite number of planets, varying in mass, distance, &c., would be capable of producing the deviations in question, so that the problem admitted of numberless solutions. It, therefore, became necessary still further to limit the question before any hope of arriving at a satisfactory answer could be entertained; and this was done by a wider application of analogy. It was assumed that the unknown planet resembled those already discovered, in the plane of its orbit being nearly the same, in the direction of its motion being similar, in its orbit being an ellipse differing but little from a circle, and in its mean distance from the sun agreeing with Bode's law of progression. Also, as it was assumed to be a planet of the solar system, it was supposed to move in accordance with Kepler's laws, and from all these hypothetical conditions, the mass of the planet sought, together with the elements of its orbit, could be calculated very precisely. This was accordingly done, and the results possessed a very high degree of probability, in consequence of the cogent analogical reasoning upon which they were based; so much so, indeed, that until something further could be obtained, the deduction might be assumed as true for all practical purposes. But it will at once be evident that the ques-

tion was susceptible of a complete settlement, as it was only necessary to calculate the position which the supposed planet would occupy on any given night, and then to look for it in that place, when, if the hypothesis were correct, the planet would be immediately *seen*. Consequently, "on the 23rd of September, 1846, Dr. Galle, one of the astronomers of the Royal Observatory at Berlin, received a letter from M. Le Verrier, announcing to him that the longitude of the sought planet must then be 326°, and requesting him to look for it. Dr. Galle, assisted by Professor Encke, accordingly did 'look for it,' and found it that very night. It appeared as a star of the eighth magnitude, having the longitude of 326° 52′, and consequently only 52′ from the place assigned by M. Le Verrier. The calculations of Mr. Adams, reduced to the same date, give for its apparent place 329° 19′, being 2° 27′ from the place where it was actually found." Thus the elimination of chance, combined with analogy, suggested a hypothesis, which assumed the rank of an established truth when the deductions from it received a complete verification.

b. Kirchhoff's Researches on the Solar Spectrum. In this case the phenomenon observed was the occurrence of various dark lines in the spectrum of a sunbeam, and to discover the cause of these constituted the question at issue. The method of Difference was first employed by showing that solid or liquid bodies, when heated to incandescence, emit rays which produce spectra differing only from the solar spectrum in the absence of dark lines: the inference drawn from this fact being that the cause of such lines must be sought among the conditions in which the two cases differed. Now it was evident that both kinds of rays proceeded from incandescent bodies, and also passed through the terrestrial atmosphere, but the solar rays, in addition to this, had to pass through the sun's atmosphere, and, therefore, in this latter condition the sought cause should be found; a conclusion which received additional strength from the analogical arguments of Sir David Brewster and Dr. Gladstone. In the next place, it had been found by experience that all transparent bodies emit, when incandescent, only those rays which they absorb when cold; thus, red glass if strongly heated appears green, yellow glass

appears purple, &c. It was also known that the spectra of incandescent *vapours* consisted simply of bright lines upon a dark ground; so, combining the two facts together, Kirchhoff conjectured that vapours comparatively cold would absorb the rays corresponding to such bright lines. Accordingly, he tried the experiment by causing the rays from a solid luminous body to pass through the vapour of sodium, and obtained a spectrum similar in every respect to that produced when no vapour was interposed, with the exception of two dark lines; these were found to be identical in position with the two yellow lines composing the spectrum of luminous sodium vapour. But, on examining the solar spectrum, two dark lines were therein perceived which corresponded exactly with those resulting from the absorptive power of vapourised sodium, and, therefore, it was evident that the presence of such a body was one of the conditions of the solar atmosphere. In a similar manner it has been ascertained that iron, nickel, calcium, magnesium, barium, copper, &c., all surround the sun in a state of vapour, and thus produce those dark lines which formed the subject of investigation. The argument may be thus thrown into a train of syllogistic inference:—

1. The facts observed being the production of uniform spectra by incandescent solids, and spectra with dark lines by the solar rays, we have the inductive syllogism, U U U:—

The difference of conditions is the cause of the difference of phenomena,

The solar atmosphere is the difference of conditions;

∴ The solar atmosphere causes the difference of the phenomena, viz., the dark lines.

2. A deduction from a law previously established, A A A:—

All transparent bodies when cold will absorb those rays which they emit when incandescent,

Sodium vapour is a transparent body;

∴ Sodium vapour when cold absorbs those rays which it emits when luminous.

3. This last conclusion is verified by experiment, and the facts now observed being the presence of two dark lines, both in the spectra from solar rays, and in those from incandescent

solids surrounded with sodium vapour, we construct a deductive syllogism in A A I, Fig. 3, based upon the two former :—

The cause of the two dark lines is sodium vapour,

The cause of the two dark lines is the solar atmosphere ;

∴ Some portion of the solar atmosphere is sodium vapour.

I may mention that I have here purposely abstained from the consideration of more causes than one being capable of producing the same effect, as, otherwise, the argument would become too perplexed for my present intention, viz., to give an example of simple logical processes when practically applied.

It would be easy to adduce many more instances of scientific discoveries, but the above, if thoroughly studied with a due recollection of the principles discussed in this treatise, will suffice to exhibit the method of analysing a complex argument into its logical elements ; and the student will be able to select for himself such other events in the history of philosophy as are well adapted for this purpose, thus putting his knowledge of mental laws to the test, and discovering what those particulars are which will be most advantageous for his individual pursuits.

§ 4. *Conclusion.*

Having now reached the end of our subject, it may not be amiss if we briefly consider the results which ought to flow from the study of a dissertation upon Logic. In the first place, we should be able to grasp the science as an organic whole, distinctly apprehending the nature of those inherent principles which compel the mind to think in one uniform manner, and forming a clear notion of the dependence which exists between them and our every act of acquiring knowledge. Secondly, we should have become accustomed to concentrate our attention upon the *process* of thought, without any reference to the matters about which it is employed. And, lastly, we should have learnt so to apply the practical principles which are deduced from a consideration of the primary mental laws, that without yielding to the blandishments of error, we may certainly attain the great temple of truth.

But I shall have written to very little purpose, if the reader be not in a position to recognise that great fact, the unity of philosophy, which, when once fully understood, lends a significance to all scientific truths, such as they otherwise would not possess; for it is the office of Logic to show that every ramification of our knowledge, however diverse, may ultimately be traced back to one parent stem; and, so far from the various sciences differing as regards their nature, it becomes a question as to whether the subjects concerning which they treat have any more than an apparent incompatibility. Therefore, he who would act in a truly philosophical spirit, must not remain satisfied with a crude, empirical acquaintance with isolated groups of facts, but should endeavour to obtain such general principles as may embrace them all; for then, not only would he obtain a more perfect knowledge of those facts themselves, but he would be enabled to gather many new truths, which, by any other method, must be lost for ever. And this may be observed in all the branches of learning: while the various facts are looked at in themselves, and by themselves, no great progress can be made; but immediately that laws, even of a comparatively limited nature, are discovered and borne in mind, then a vast impulse is given, the effects of which will speedily become apparent. At the same time, we should remember the intimate connection of reflection with observation, and endeavour not to cultivate one at the expense of the other.

Logic, then, may be considered as abstract philosophy, that system of which all other sciences are but the concrete manifestations; and, therefore, he alone can be justly termed a philosopher who has made himself acquainted with the laws that regulate the working of his own thoughts. But a mere acquaintance, in the ordinary sense of the word, will by no means suffice; for, as Archbishop Thomson observes, 'philosophy does not exist until the mind of the student begins to work for itself with the principles it receives historically; to decompose and to compose anew, to criticise the arguments employed, to essay at least to push the confines of truth farther into the wilds of error and ignorance, and to leave her a wider territory." In other words, we should not

become accustomed to acquiesce as a matter of course in the assertions with which we meet, nor to imagine that the subject is capable of no further development; but, by actively applying the powers of our own minds to the elucidation of the question, we should endeavour to ascertain the precise amount of truth which inheres in the principles laid down, and to add something however small, to the previously accumulated store of knowledge.

The end, accordingly, at which all should aim who desire the proper cultivation of their intellects, is rectification and progression—the correct adjustment of opinions already entertained, and the establishment of views more wide and lofty; for, as this can only be done by a recourse to the latent powers of their own understandings, it will assuredly result both in a surprising accession of vigour to the individual mind, and in great benefits to the world at large. Nor can it be doubted that the practice of thought, when duly controlled by the regular operation of its formal laws, must highly conduce in the promotion of mental calmness and sobriety: no longer led astray by the influence of passion, or deceived by the representations of the senses, the well-ordered intellect, secure and undisturbed, reviews by the light of necessary truth those facts which come under its notice, and delivers judgment in strict accordance with the immutable laws of nature.

In conclusion, I would remark that by far the noblest subject of human investigation is the human mind. The science of astronomy may give rise to emotions of awe and sublimity as we contemplate the vast infinitude of space, with its myriads of worlds and systems of worlds; geology may astonish us with its record of the marvellous forms of life which have successively inhabited the earth; the physical sciences may endue us with power so prodigious, as to become almost miraculous; but yet, the fascination which attends every inquiry into the nature of our own being, must always cause the study of mental philosophy to take its place as the most mysterious and attractive object of all our speculations.

APPENDIX.

A.

On Judgments.

In the body of this treatise, I have (p. 27) described judgment as "the act of determining by comparison, whether one idea is or is not included within another," and have referred it to the motive faculty of classification. But as the subject is one of great importance, and has much influence upon a due appreciation of logical science, I deem it advisable to append some further observations which shall enable the student to form a completer notion of the import which attaches to predication.

Now the most useful manner of introducing such remarks will be to criticise the most important objections which have been made to the above views; and for this purpose I shall select the following passage from Mr. Mill's "System of Logic," (vol. i. p. 104). "This theory appears to me a signal example of a logical error very often committed in logic, that of *ὕστερον προτέρον*, or explaining a thing by something which presupposes it. When I say that snow is white, I may and ought to be thinking of snow as a class, because I am asserting a proposition as true of all snow: but I am certainly not thinking of white objects as a class; I am thinking of no white object whatever except snow, but only of that, and of the sensation of white which it gives me. When, indeed, I have judged or assented to the propositions, that snow is white, and that several other things are also white, I gradually begin to think of white objects as a class, including snow and those other things. But this is a conception which followed, not preceded, those judgments, and

therefore cannot be given as an explanation of them. Instead of explaining the effect by the cause, this doctrine explains the cause by the effect, and is, I conceive, founded on a latent misconception of the nature of classification."

In the expression "when I say that snow is white," Mr. Mill evidently alludes to the formation of such a judgment *before* the conception of a class of white objects, for he says shortly after, "This [white objects as a class] is a conception which *followed*" the establishment of similar propositions; and as this is the ground upon which he charges the classificatory doctrine of judgment with error, his argument will be sufficiently refuted by showing that it is impossible to form the proposition "snow is white," before recognising white objects as a *class*.

And first, let Mr. Mill himself be brought forward as a witness: he says (vol. i. p. 30), "When we say snow is white, milk is white, linen is white, we do not mean it to be understood, that snow, or linen, or milk, is a colour. We mean that they are *things* having the colour." Therefore the meaning of the proposition is, so far, that snow is a white object. It must next be shown that we cannot think of "*a* white object," by itself, but that we always think of "*some* (or all) white objects," that is, of a class; and this may be done by a reference to the process of abstraction. For, as was seen at an early stage of our logical studies, it is necessary that such a process should be completed before we are able to possess any common notion or abstract term; and, therefore, the idea "white" is the result of comparison, reflection, abstraction, generalisation, and denomination, the first four of these being simultaneous, a fact which will become evident upon pushing our analysis a little further. Thus, suppose we had never obtained the idea of "white," or of any other common notion, and that we met with the object "snow:" the impression produced upon our senses would be a combination of such sensations as solidity, granular structure, absence of what is commonly termed colour, &c., but we should find it altogether impossible to separate this compound idea into its various parts; consequently, the only notion obtained would be an *intuition*, and we should be unable to form any other judgment than that "snow is snow." Immediately, however, that we met with any other intuition, say "milk," we should receive an immense acquisition to our knowledge; we should instinctively, as it were, compare them, and thus

perceive that although the two objects resembled each other in some respects, yet that they differed in others; that, for example, in one object a solution of molecular continuity was easily observable, while in the other such a condition did not obtain; that snow offered some resistance to a change of shape, while milk did not; but also that the intuitions produced by both were partly indistinguishable. This fact would compel us to recognise that the idea ("snow") which we had previously considered as simple, was in reality compound; or, in other words, that it was capable of division: for we should have sensible evidence that a part of it could exist without the remainder. Accordingly, we should see that snow and milk were separate objects, but yet, as far as our minds were concerned, partially identical; that is to say, we should recognise a *class* composed of two individuals. Now the whole of the preceding mental action would take place in equal progression, for with the commencement and advance of comparison, would commence and advance, *pari passu*, reflection, abstraction, and generalisation. But after this was concluded as far as would suit our more immediate purpose, we should take some measure to prevent our forgetting its results, and this would be the imposition of an abstract term, together with its correlative concrete. In the present case we should term that sensation in which both intuitions agreed, "whiteness," and then we should form the proposition "snow and milk are white objects;" or, in more detail, we should say, "snow is white, and milk is white." Therefore, it will be evident that no judgment (excluding such as are tautologous) can be formed without the conception of a class composed of at least two individuals; although, in most cases, a general name cannot be imposed until after the comparison of many objects, and the recognition of a proportionately larger class. But it must here be borne in mind, that when once we have gone beyond the idea of unity, there is no definite limit which we can impose upon our powers of imagination; and, accordingly, no sooner is a general notion conceived, than we regard the class as hypothetically infinite. This hint will, I hope, prove sufficient to prevent the opinion being entertained that classification is *merely* "an arrangement and grouping of *definite* and *known* individuals;" and that the doctrine above stated implies the theory, "that when names were imposed, mankind took into consideration all the individual objects in the universe, distributed them into parcels

or lists, and gave to the objects of each list a common name, repeating this operation *toties quoties*, until they had invented all the general names of which language consists." (Mill's "Logic," vol. i. p. 105.)

It has now, I apprehend, been irrefragably demonstrated that the classificatory doctrine of predication rests upon valid grounds, and that the objections considered above are untenable. Indeed, so simple and natural is the theory, that even Mr. Mill himself, when not engaged in actual combat therewith, implicitly affords his support to it, as witness the following passage:—"A child learns the meaning of the words *man* or *white*, by hearing them applied to a *variety* of individual objects, and finding out, by a process of *generalisation* and *analysis* of which he is but imperfectly conscious, what those different objects have in common." (Vol. i. p. 39.) If this mean that an abstract notion and its concrete cannot be formed from the observation of a single object—and certainly neither from the passage itself, nor from the context can I suppose any other signification intended—then the whole question at issue is granted, since the idea of a class is merely the conception of two or more individuals resembling each other in certain respects.*

I have already taken occasion to protest against Archbishop Thomson's exposition of judgment, but my remarks must not be held to refer to anything beyond the terminology employed, as it is possible that the doctrine so ambiguously put forth, may, in all essential points, be that of classification. Thus, speaking of the proposition "All men are animals," Dr. Thomson says, "We mean by our judgment, not that men and animals are just the same things, but that men are *contained in* [*sic*] the wider class animals." ("Outlines," p. 151.)

And as regards my own statement (p. 28) that the copula of a proposition signifies "the identicality of the subject and predicate, such *identicality* being, however, *limited* by the form of the proposition," I must refer the reader for a more complete explication of its import, to the foregoing analysis of the manner in which common terms are formed.

* It may be proper to observe that in the above quotations many of the italics are my own.

B.

On the so-called Immediate Inferences.

These are such arguments as were discussed under the heads of opposition, conversion, and coincident junction; and since a universal misconception appears to exist regarding their real nature, it may be worth while to present the reader with some additional information upon this point.

And first, it will be necessary to prove that an *inference* takes place in these processes, for many logicians exclude them altogether from the sphere of reasoning. Now, I cannot do this better than by adopting the words of Archbishop Thomson, a philosopher to whom the science of Logic is under very great obligations; and therefore, without further apology, I proceed to quote the following remarks:—

"Some logicians refuse the name of inference to this and similar processes [those named above], on the ground that 'there is in the conclusion no new truth, nothing but what was already asserted in the premises, and obvious to whoever apprehends them.' That the conclusion is *virtually* asserted in the premises, is true not only of these immediate inferences but of all syllogisms whatever; even in the inductive, the mere consequence—the act of concluding—brings in nothing which is not known potentially as soon as we have the whole grounds before us. So that the objection proves too much; as it would disqualify a set of inferences which no one thinks of rejecting. If, however, there is absolutely nothing new—if the concession of the premiss is not only a virtual, but an actual and express declaration of the conclusion, there is no inference, but mere repetition. But who can say that 'no unjust rulers are good' is a bare repetition of 'all good rulers are just?' In the one we affirm, in the other deny; in the one the subject of thought is 'good rulers,' in the other, 'unjust rulers.' They are, in these two points at least, distinct judgments, and as the passing of the one makes it possible, without further observation or decision upon facts, to collect the other, there is an inference. In many such cases, it is true, the inference is so obvious, so certain to occur upon the first glance at the premiss, that it seems needless to draw it out; but all the inferences we are about to specify are used from time to time, and this entitles them to our consideration."

The above passage will suffice for the establishment of the arguments in question as inferences; it now remains to prove that they are *mediate* inferences. And here it may be remarked as somewhat singular, that so acute a thinker as Dr. Thomson should have made such a near approach to the whole truth, and yet should have grasped but a portion; for it will be observed that although he clearly perceives the conclusion to result from a process of reasoning, he still maintains that it is dependent upon one premiss only; a doctrine which probably arises from the very fact that arrests his attention, viz., the obviousness and transparency of the inference—this rendering him loth to suppose the existence of a syllogistic deduction in so simple an operation, as, in like manner, it prevented the older logicians from admitting the presence of any reasoning whatever, no matter how supposedly direct it might be.

I shall, accordingly, proceed to enunciate the several principles upon which the validity of the inferred propositions rests; and if they are obviously essential, the doctrine here advocated must be admitted as established.

1. Opposition:—

a. Contradictory. *Any two classes must be either mutually and wholly exclusive or mutually and partially inclusive.* This canon is necessitated by the laws which regulate our thoughts, and therefore, as far as Logic is concerned, must be considered fundamental. Its meaning is that we cannot think of any two classes, except in one of the manners stated; and from it are developed these judgments:—"If E be true, I is false;" "If E be false, I is true;" "If I be true, E is false;" and "If I be false, E is true;" which respectively serve as major propositions in any particular case where this kind of opposition may be employed, the judgment operated upon serving as a minor. Thus, admitting the fact that "no men have wings," we must also admit that the statement "some men have wings" is false; for,

If E be true, I is false,
E ("no men have wings") is true;
∴ I ("some men have wings") is false.

Now, a moment's inspection will show that unless the major be here assumed, there can be no inference.

b. Contrary. *Neither the mutual and total exclusion of two classes, nor their mutual and partial inclusion, can be thought at the same time with their mutual and total inclusion.* By

development from this canon we obtain such majors as may be required, varying with the form of the original proposition; for example, if the position of A be employed as a minor premiss we may conclude that E, U, O, and Y are false, by employing the major "If A be true, then E, U, O, and Y are all false."

c. Subaltern. *Whatever relation exists between two classes, the same exists between any portions of those classes.* Here will be observed a modification of Aristotle's *dictum;* for when we assert that the whole of one class is or is not contained in another, we must also be able to assert that a portion of it is similarly characterised; and so on, to a full exposition of the canon, with its resulting majors.

d. Subcontrary. *Any two classes must be either mutually and wholly exclusive* (*when, by the last canon, we may assert them as mutually and partially exclusive*), *or they must be mutually and partially inclusive.* This canon is at once seen to be a corollary from the first and third; it can only refer to cases of I and O, the majors being respectively, "If I be false, O is true;" and "If O be false, I is true."

2. Conversion:—

a. Simple. *Those magnitudes which coincide are equal.* This canon, common both to geometry and logic, will hardly be questioned. The explication of its present import is that when two classes, or parts of classes, comprise the same objects, or when two individuals comprise the same ideas, they may at pleasure replace each other as subject and predicate in any form of proposition. We are, therefore, entitled to assume for majors, "If A be true, the corresponding Y is," etc.

b. Privative. *Every object of thought must be either a positive idea or its correlate privative.* Now, since these ideas are mutually and wholly exclusive, we are manifestly enabled to infer the presence of one from the absence of the other, and *vice versâ.* From this development of the canon, we must educe such majors as may be required from time to time; thus —

No immaterialities are material,
All forces are immaterialities;
∴ No force is material.

3. Coincident Junction:—

The canon of this doctrine is, "*Whatever is joined to one of two or more inseparable ideas, is joined to all.*" That is to

say, if we must always think simultaneously of two objects, and we think of one of these at the same time with a third, the other must in like manner be conceived. Accordingly, we may construct as many syllogisms as we please of the following form :—

Whatever may be added to the subject of an admitted proposition may at the same time be added to its predicate,

"Red" may be added to the subject of the admitted proposition, "metals are solids;"

∴ It may be added at the same time to the predicate —*e.g.*, "red metals are red solids."

Thus have I shown that every so-called immediate inference is, in reality, of a syllogistic nature; for let any of the above-mentioned majors be denied, and the conclusion is no longer valid. The object with which I set out is, therefore, attained; but ere I conclude, it will be useful to make a few brief observations upon some detached portions of the subject.

I have then to remark that as regards simple conversion, it must not be thought of as only applicable to tautologous judgments; for, as shown by the table given in page 45, every possible proposition may be simply converted. Nor must it be held that the convertend and its converse are the expressions of the same operations of thought; for confessedly, the respective *subjects* about which we think are different. Therefore, when, speaking of conversion, Sir William Hamilton states ("Logic," Appendix, V. c.) that "it is of no consequence, in a logical point of view, which of the notions collated" are "subject or predicate," he would appear either to have been bestowing too little attention upon the *process* of thinking, or to have expressed himself ambiguously.

I may also mention that Mr. Mill, who repudiates the notion of inference when applied to the above processes, has himself made a remark which affords a key to the whole question. He is alluding to "such considerations as these, that contrary propositions may both be false, but cannot both be true; that subcontrary propositions may both be true, but cannot both be false," etc., etc.; which the reader will immediately recognise as modifications of the canons above given; and says that "in this respect [*i.e.*, as involving general principles], these *axioms* of Logic are on a level with those of mathematics." He also implicitly terms them "elementary generalisations," but yet does not see that any one operation of opposition, etc.,

is as regular a deduction from a "general truth" as is any reasoning of geometry or algebra, which depends upon precisely similar axioms. (Compare Mill's "Logic," Book ii. chap. 1, § 2.)

C.

On the Dictum de Omni et Nullo

This canon I have enunciated (p. 8) in the following terms:—"Whatever is affirmed or denied altogether of any whole, may in like manner be affirmed or denied of any individual part belonging to, or comprehended in that whole;" and I have here used the word "whole" (the customary term being "class") in order that the principle might be more *obviously* applicable to syllogisms having singular terms. It will, however, be necessary to present in this place a more explicit view of the *dictum* than I have hitherto done; for otherwise, the objections frequently urged against that law might possibly be considered as unanswerable.

We have seen already (article A) that the notion of a class, or a "common notion," is the complex idea of an indefinite number of individual members all possessing the same characteristic, and also that the notion of an individual, or a "singular notion," is the complex idea of an indefinite number of attributes, most of them being class-characteristics, and all possessing the same unity of connection. Therefore, as a "class" and its "members" are, for all present purposes, precisely equipollent with an "individual" and its "attributes," I shall use the terms "whole" and "parts," which will serve equally well to represent either of the former pairs.

We are now able to perceive a fact which lies at the very root of the question, viz., that a "whole" is not composed merely of its "parts," but that it contains in addition the "unity" which obtains among them. And also—as was shown in the sections of this treatise which discussed the subjects of *formal* induction, deduction, extension and comprehension—we know that it is possible to direct at pleasure the major part of our attention upon either of the above con-

stituents of a "whole," upon the "unity," or upon the "parts."

Thus much premised, I have next to point out a very important distinction, viz., the relative powers of conceiving the "unity" and the "parts." The "unity" is obviously a *single* object of thought; the "parts" are, on the contrary, not merely a numerous, but an indefinitely numerous *collection* of such objects: therefore, while it is possible to form a clear and precise notion of the "unity," we can only obtain a vague and indefinite idea of the "parts." Hence it results that we can always direct a greater portion of our attention upon the "unity," than upon the "parts;" for that which we can perform more easily, we can perform better; and as a corollary, we see that the natural disposition of the mind is to regard the "unity" as pre-eminent, the "parts" as subordinate.

The *dictum* results from the facts thus proved: it asserts that whatever is recognised as belonging to, or excluded from, the "whole," when principally looked upon as the "unity," will be found to hold the same relation, not to the "parts" in a body—for they, although vaguely conceived, yet form an essential constituent of the "whole," and are at least *co-extensive* with "unity"—but to any *one* of the "parts," no matter whether it be already known as individually existing, or whether it have yet to be rescued from the depths of indefinity. And as I have formerly shown that all judgments are classifications (Appendix A), and that all reasoning whatever may be exhibited in syllogisms (*passim*)—these doctrines, taken in connection with the proof just now afforded, that the *dictum* is a necessary law of thought, will, I apprehend, make it evident that the Stagirite's canon is the organic principle of all inference.

That the above remarks were not altogether uncalled for, I shall show by quoting the following passage from Mr. Mill's "Logic" (Book ii. chap. ii. § 2); my reason for selecting this author being that he is one of the ablest and best known of the logicians adopting similar views:—

"Now, however, when it is known that a class, an universal, a genus or species, is not an entity *per se*, but neither more nor less than the individual substances themselves which are placed in the class, and that there is nothing real in the matter except those objects, a common name given to them, and common attributes indicated by the name; what, I should

be glad to know, do we learn by being told, that whatever can be affirmed of a class, may be affirmed of every object contained in the class? The class *is* nothing but the objects contained in it; and the *dictum de omni* merely amounts to the identical proposition, that whatever is true of certain objects, is true of each of those objects. If all ratiocination were no more than the application of this maxim to particular cases, the syllogism would indeed be what it has so often been declared to be, solemn trifling. The *dictum de omni* is on a par with another truth, which in its time was also reckoned of great importance, 'Whatever is, is.' To give any real meaning to the *dictum de omni*, we must consider it not as an axiom, but as a definition; we must look upon it as intended to explain, in a circuitous and paraphrastic manner, the meaning of the word *class*." The italics here are Mr. Mill's.

In what points the above passage differs from the doctrine previously advocated, and which view is supported by the more weighty arguments, are questions that must be left for each reader to decide for himself. Suffice it if a clear statement of the facts involved has been put forward.

I have frequently spoken of Aristotle's *dictum* as being the fundamental law of inference; but I should here wish to qualify that expression by stating that I do not use the word "fundamental" in its most explicit sense; that is to say, I do not imply the non-existence of some more recondite and general principle. My only meaning is, that for all logical purposes, it will be sufficient to consider the *dictum*, *i.e.*, the practical law by which the motive faculty of classification works, as the ultimate principle of thought as thought: to the end that we may not be compelled to encroach upon metaphysical ground.

In this connection it may be useful to mention that by many writers the fundamental laws of thought have been given as follows:—

1. The Law of Identity. "A concept is equal to all its characters," or, "A thing is equal to itself."

2. The Law of Contradiction. "What is contradictory is unthinkable."

3. The Law of Exclusion. "Either a given judgment must be true, or its contradictory; there is no middle course."

4. The Law of Sufficient Reason. "Whatever exists or is true, must have a sufficient reason why the thing or proposition should be as it is, and not otherwise."

I shall content myself with having called the reader's attention to these laws, and shall not attempt to discuss them in the present place. I may, however, refer to Sir William Hamilton's fifth and sixth lectures upon Logic, as containing an able analysis of the principles in question.

D.

On the Syllogism considered as a Petitio Principii.

The form which this objection to the syllogism generally assumes is thus stated by Mr. Mill :—

"It must be granted that in every syllogism, considered as an argument to prove the conclusion, there is a *petitio principii*. When we say,

All men are mortal,
Socrates is a man ;
Therefore,
Socrates is mortal ;

it is unanswerably urged by the adversaries of the syllogistic theory, that the proposition, Socrates is mortal, is pre-supposed in the more general assumption, All men are mortal: that we cannot be assured of the mortality of all men, unless we are already certain of the mortality of every individual man: that if it be still doubtful whether Socrates, or any other individual you choose to name, be mortal or not, the same degree of uncertainty must hang over the assertion, All men are mortal: that the general principle, instead of being given as evidence of the particular case, cannot itself be taken for true without exception, until every shadow of doubt which could affect any case comprised with it, is dispelled by evidence *aliundè*, and then what remains for the syllogism to prove? That, in short, no reasoning from generals to particulars can, as such, prove anything; since from a general principle we cannot infer any particulars, but those which the principle itself assumes as known."

"This doctrine," Mr. Mill goes on to add, "appears to me irrefragable," and the mode of issuing from the difficulty which he adopts, is to deny that the syllogism as such is an

inference. He asserts that the same evidence which enabled us to infer the general truth "All men are mortal," would equally enable us to draw the particular conclusion "Socrates is mortal;" and that a true representation of the reasoning process which takes place, would be to say that as Solon, Lycurgus, Pisistratus, and other individuals possessed the attribute mortality, and as Socrates resembles those individuals in his possession of the attribute humanity, he will therefore resemble them in being mortal. This "type of ratiocination," says Mr. Mill, "does not claim, like the syllogism, to be conclusive from the mere form of expression; nor can it possibly be so. . . . . Whether, from the attributes in which Socrates resembles those men who have heretofore died, it is allowable to infer that he resembles them also in being mortal, is a question of induction; and is to be decided by the principles or canons which we shall hereafter recognise as tests of the correct performance of that great mental operation."

It will thus be seen that in refusing the name of inference (strictly speaking) to syllogistic reasoning, and in referring it to induction, Mr. Mill evidently considers the latter as altogether different in nature from the syllogism. It would not be difficult to quote other passages to the same effect, thus—"This was induction, but bad induction; just as a vicious syllogism is reasoning, but bad reasoning," where the processes of induction and syllogism are contrasted. Consequently, the theory of induction maintained in the body of this treatise, is directly at variance with the views just stated; for I have endeavoured to show that the inductive process is merely a peculiar species of deductive (syllogistic) inference, and depends altogether upon reasonings which assume the form of syllogisms. It is necessary, then, to produce some considerations which shall serve to establish the fact that Mr. Mill is mistaken in supposing induction to be independent of syllogism.

Now this point may, I think, be proved by using Mr. Mill's own words. First, as regards inductions in general, I find the following statement:—"It hence appears that if we throw the whole course of any inductive argument into a series of syllogisms, we shall arrive, by more or fewer steps, at an ultimate syllogism, which will have for its major premiss the principle, or axiom, of the uniformity of the course of nature." A passage like this might apparently be held as

an admission of all that I require to prove; I shall, however, push the matter a little further, and ask, Upon what does Mr. Mill rest his "ultimate major premiss?" The answer I find to be, "We arrive at this universal law, by generalisation from many laws of inferior generality." But here another step presents itself, which leads us to inquire what it is that gives validity to this last-mentioned "generalisation," which is described in another place as being an "induction by simple enumeration—in other words, generalisation of an observed fact from the mere absence of any known instance to the contrary;" or, to vary the expression, what makes us certain that the conclusion to which this generalisation conducts is true? The only approach to a reply which Mr. Mill gives, is as follows:—

"The considerations which, as I apprehend, give, at the present day, to the proof of the law of uniformity of succession, as true of all phenomena without exception, this character of completeness and conclusiveness, are the following:—First, that we now know it directly to be true of far the greatest number of phenomena; that there are none of which we know it not to be true, the utmost that can be said being that of some we cannot positively from direct evidence affirm its truth; while phenomenon after phenomenon, as they become better known to us, are constantly passing from the latter class into the former; and in all cases in which that transition has not yet taken place, the absence of direct proof is accounted for by the rarity or obscurity of the phenomena, our deficient means of observing them, or the logical difficulties arising from the complication of the circumstances in which they occur; insomuch that, notwithstanding as rigid a dependence on given conditions as exists in the case of any other phenomenon, it was not likely that we should be better acquainted with those conditions than we are."

Accordingly, the *observed* ground for the conclusion that all phenomena have a cause, is the fact that *some* have; but there is no reason assigned for such an inference being valid. I can therefore only suppose that Mr. Mill implies the existence of some mental law which assures us of a particular uniformity so characterised being sufficient to warrant the truth of the corresponding general uniformity. And this view is borne out by such statements as this—"The unprompted tendency of the mind is to generalise its experience provided this points all in one direction," which are to be

frequently met with in the work quoted. The result, then, at which we finally arrive, is that the mind supplies a general law, according to which, if certain facts are ascertained by observation, a fixed conclusion must be obtained. Let us state this mental law, the observed facts, and the conclusion in the order named, thus :—

A case of a certain particular uniformity is a case of the corresponding general uniformity,
The case of some phenomena being caused is such a particular uniformity ;
∴ The case of some phenomena being caused is a case of all phenomena being caused.

This evidently is nothing but a syllogism, and indeed is precisely the same syllogism as that to which, in the body of this treatise, I traced all induction. A comparison of the investigation then followed out, with that just concluded, will thus show that Mr. Mill implicitly, and myself explicitly, are agreed in considering induction as but a species of syllogistic inference.

It now remains to prove that the syllogism is not obnoxious to the charge of depending upon a *petitio principii ;* and this may, I think, be done in two ways. First, making use of the fact recently established, that all reasoning whatever is syllogistic, it can fairly be maintained, that even if it were impossible to directly point out any flaw in the argument supporting the charge ; yet there must of necessity be one somewhere, or otherwise no valid inference could ever exist. But, secondly, the alleged fallacy may be disposed of, in the following manner, by a reference to the simple processes of thought.

Taking the example already used, *i. e.*, "All men are mortal, Socrates is a man ; therefore, Socrates is mortal," let us consider whether or not the major premiss *alone* contains the conclusion. The subject is the class "man" taken universally, that is, as a whole, and accordingly, the object which occupies our thoughts is composed principally of the unity "humanity." The predicate is the class "mortal things," considered mainly with reference to a portion of its "parts ;" and the import of the entire judgment is that "humanity" is one of the unities possessing "mortality," and that the parts which are connected together by humanity form a complex portion of the parts connected by mortality. Now the only assertion which is here made respecting individual objects is

that any case of "*humanity*" is a case of "mortality," and therefore it is *not* implied that any *intuition* such as Socrates, Plato, or Junius, is mortal, *until* such intuition has been analysed and found to contain "humanity." Then, indeed, I grant, the major premiss implies the conclusion; *but then*, it must be borne in mind, we are also in possession of the *minor premiss, without which the conclusion would not be so implied.* Accordingly, the major tells us that the *general notion* "man" forms a portion of the general notion "mortal things;" the minor, that the *intuition* Socrates forms a portion of the general notion "man;" the conclusion, that the *intuition* Socrates forms a portion of the general notion "mortal things." And thus it will also be seen, that both the major and minor premises *separately* contain the conclusion *when* both are admitted; but that, unless this be the case, *neither* of them does. Therefore, as *both* premises are essential to the conclusion, there is no *petitio principii.*

The above is necessarily but a mere outline of the argument by which the syllogistic theory, as ordinarily, and I apprehend, justly received, may be defended. The full details cannot here be set forth, and therefore I must ask the reader to supply them himself, a task which will be easy when once he is in possession of the key to the whole question, viz., when he perceives the distinction which must be made between an *intuition as an intuition*, and an *intuition resolved into its constituting general notions.*

In this article, the work quoted from is Mr. Mill's "Logic," and I annex a list of the passages referred to, in the order of their occurrence above.

Propositions, formation of, 27; classification of, 33; table of possible, 33; quantity of, 30; quality of, 30.
Propositions, affirmative and negative, 30; alternative or disjunctive, 29; ampliative, explicative, and tautologous, 35; attributive and substitutive, 32; categorical, 28; conditional or hypothetical, 29; partial-negative and total-negative, 32; particular and universal, 30.
Prosyllogism, 79.
Pure categoricals, 28.

Quality, 30.
Quantity, 30.

Reasoning in general, 38.
Reduction, 55.
Reflection, 126; examples of 148, 150.
Relation, 32.
Relative terms, 23.

Science, its object, 117.
Simple-apprehension, 14.
Singular terms, 11, 15.
Sorites, Aristotelian, 76; Goclenian, 77.
Species, 17; *infima*, 17.
Substitutive propositions, 32.
Syllogism, shown to be no *petitio principii*, 166.
Syllogisms, 39; valid, table of, 58; conditional, 67; reduction of conditional, 69.
Sir W. Hamilton's objections to reduction of conditional syllogisms refuted, 70.
Syllogisms, disjunctive, 72; reduction of, 72.
Syllogisms, incomplete, 75.
Syncategorematic terms, 24.

Tautologous propositions, 35.
Terms, distribution of, 31; relation of, 32; absolute and relative, 23; abstract and concrete, 23; attributive or connotative, 23; categorematic and syncategorematic, 24; common and singular, 11; compatible and opposite, 23; correlative, 23; definite and indefinite, 22; positive, privative, and negative, 20 univocal, equivocal, and analogous, 23.
Total-negative propositions, 32.

Universal propositions, 30.
Univocal terms, 23.

Verification, 142.

THE END.

PRINTED BY J. S. VIRTUE AND CO., LIMITED, CITY ROAD, LONDON.

Weale's Rudimentary Series.

LONDON, 1862.

THE PRIZE MEDAL

Was awarded to the Publishers of

"WEALE'S SERIES."

A NEW LIST OF

WEALE'S SERIES

RUDIMENTARY SCIENTIFIC, EDUCATIONAL, AND CLASSICAL.

Comprising nearly Three Hundred and Fifty distinct works in almost every department of Science, Art, and Education, recommended to the notice of Engineers, Architects, Builders, Artisans, and Students generally, as well as to those interested in Workmen's Libraries, Literary and Scientific Institutions, Colleges, Schools, Science Classes, &c., &c.

☞ "WEALE'S SERIES includes Text-Books on almost every branch of Science and Industry, comprising such subjects as Agriculture, Architecture and Building, Civil Engineering, Fine Arts, Mechanics and Mechanical Engineering, Physical and Chemical Science, and many miscellaneous Treatises. The whole are constantly undergoing revision, and new editions, brought up to the latest discoveries in scientific research, are constantly issued. The prices at which they are sold are as low as their excellence is assured."—*American Literary Gazette.*

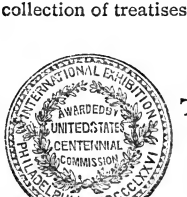
"Amongst the literature of technical education, WEALE'S SERIES has ever enjoyed a high reputation, and the additions being made by Messrs. CROSBY LOCKWOOD & SON render the series more complete, and bring the information upon the several subjects down to the present time."—*Mining Journal.*

"It is not too much to say that no books have ever proved more popular with, or more useful to, young engineers and others than the excellent treatises comprised in WEALE'S SERIES."—*Engineer.*

"The excellence of WEALE'S SERIES is now so well appreciated, that it would be wasting our space to enlarge upon their general usefulness and value."—*Builder.*

"The volumes of WEALE'S SERIES form one of the best collections of elementary technical books in any language."—*Architect.*

"WEALE'S SERIES has become a standard as well as an unrivalled collection of treatises in all branches of art and science."—*Public Opinion.*



PHILADELPHIA, 1876.

THE PRIZE MEDAL

Was awarded to the Publishers for

Books: Rudimentary, Scientific,

"WEALE'S SERIES," ETC.

CROSBY LOCKWOOD & SON,

7, STATIONERS' HALL COURT, LUDGATE HILL, LONDON, E.C.

WEALE'S RUDIMENTARY SCIENTIFIC SERIES.

*** The volumes of this Series are freely Illustrated with Woodcuts, or otherwise, where requisite. Throughout the following List it must be understood that the books are bound in limp cloth, unless otherwise stated; *but the volumes marked with a ‡ may also be had strongly bound in cloth boards for 6d. extra.*

N.B.—In ordering from this List it is recommended, as a means of facilitating business and obviating error, to quote the numbers affixed to the volumes, as well as the titles and prices.

CIVIL ENGINEERING, SURVEYING, ETC.

No.

31. *WELLS AND WELL-SINKING.* By JOHN GEO. SWINDELL, A.R.I.B.A., and G. R. BURNELL, C.E. Revised Edition. With a New Appendix on the Qualities of Water. Illustrated. 2s.

35. *THE BLASTING AND QUARRYING OF STONE,* for Building and other Purposes. By Gen. Sir J. BURGOYNE, Bart. 1s. 6d.

43. *TUBULAR, AND OTHER IRON GIRDER BRIDGES,* particularly describing the Britannia and Conway Tubular Bridges. By G. DRYSDALE DEMPSEY, C.E. Fourth Edition. 2s.

44. *FOUNDATIONS AND CONCRETE WORKS,* with Practical Remarks on Footings, Sand, Concrete, Béton, Pile-driving, Caissons, and Cofferdams, &c. By E. DOBSON. Seventh Edition. 1s. 6d.

60. *LAND AND ENGINEERING SURVEYING.* By T. BAKER, C.E. Fifteenth Edition, revised by Professor J. R. YOUNG. 2s.‡

80*. *EMBANKING LANDS FROM THE SEA.* With examples and Particulars of actual Embankments, &c. By J. WIGGINS, F.G.S. 2s.

81. *WATER WORKS,* for the Supply of Cities and Towns. With a Description of the Principal Geological Formations of England as influencing Supplies of Water, &c. By S. HUGHES, C.E. New Edition. 4s.‡

118. *CIVIL ENGINEERING IN NORTH AMERICA,* a Sketch of. By DAVID STEVENSON, F.R.S.E., &c. Plates and Diagrams. 3s.

167. *IRON BRIDGES, GIRDERS, ROOFS, AND OTHER* WORKS. By FRANCIS CAMPIN, C.E. 2s. 6d.‡

197. *ROADS AND STREETS.* By H. LAW, C.E., revised and enlarged by D. K. CLARK, C.E., including pavements of Stone, Wood, Asphalte, &c. 4s. 6d.‡

203. *SANITARY WORK IN THE SMALLER TOWNS AND IN* VILLAGES. By C. SLAGG, A.M.I.C.E. Revised Edition. 3s.‡

212. *GAS-WORKS, THEIR CONSTRUCTION AND ARRANGEMENT;* and the Manufacture and Distribution of Coal Gas. Originally written by SAMUEL HUGHES, C.E. Re-written and enlarged by WILLIAM RICHARDS, C.E. Eighth Edition, with important additions. 5s. 6d.‡

213. *PIONEER ENGINEERING.* A Treatise on the Engineering Operations connected with the Settlement of Waste Lands in New Countries. By EDWARD DOBSON, Assoc. Inst. C.E. 4s. 6d.‡

216. *MATERIALS AND CONSTRUCTION;* A Theoretical and Practical Treatise on the Strains, Designing, and Erection of Works of Construction. By FRANCIS CAMPIN, C.E. Second Edition, revised. 3s.‡

219. *CIVIL ENGINEERING.* By HENRY LAW, M.Inst. C.E. Including HYDRAULIC ENGINEERING by GEO. R. BURNELL, M.Inst. C.E. Seventh Edition, revised, with large additions by D. KINNEAR CLARK, M.Inst. C.E. 6s. 6d., Cloth boards, 7s. 6d.

268. *THE DRAINAGE OF LANDS, TOWNS, & BUILDINGS.* By G. D. DEMPSEY, C.E. Revised, with large Additions on Recent Practice in Drainage Engineering, by D. KINNEAR CLARK, M.I.C.E. Second Edition, Corrected. 4s. 6d.‡

☞ *The ‡ indicates that these vols. may be had strongly bound at 6d. extra.*

MECHANICAL ENGINEERING, ETC.

33. *CRANES*, the Construction of, and other Machinery for Raising Heavy Bodies. By JOSEPH GLYNN, F.R.S. Illustrated. 1s. 6d.
34. *THE STEAM ENGINE*. By Dr. LARDNER. Illustrated. 1s. 6d.
59. *STEAM BOILERS:* their Construction and Management. By R. ARMSTRONG, C.E. Illustrated. 1s. 6d.
82. *THE POWER OF WATER*, as applied to drive Flour Mills, and to give motion to Turbines, &c. By JOSEPH GLYNN, F.R.S. 2s.‡
98. *PRACTICAL MECHANISM*, the Elements of; and Machine Tools. By T. BAKER, C.E. With Additions by J. NASMYTH, C.E. 2s. 6d.‡
139. *THE STEAM ENGINE*, a Treatise on the Mathematical Theory of, with Rules and Examples for Practical Men. By T. BAKER, C.E. 1s. 6d.
164. *MODERN WORKSHOP PRACTICE*, as applied to Steam Engines, Bridges, Ship-building, &c. By J. G. WINTON. New Edition. 3s. 6d.‡
165. *IRON AND HEAT*, exhibiting the Principles concerned in the Construction of Iron Beams, Pillars, and Girders. By J. ARMOUR. 2s. 6d.‡
166. *POWER IN MOTION:* Horse-Power, Toothed-Wheel Gearing, Long and Short Driving Bands, and Angular Forces. By J. ARMOUR, 2s.‡
171. *THE WORKMAN'S MANUAL OF ENGINEERING* DRAWING. By J. MAXTON. 7th Edn. With 7 Plates and 350 Cuts. 3s. 6d.‡
190. *STEAM AND THE STEAM ENGINE*, Stationary and Portable. By J. SEWELL and D. K. CLARK, C.E. 3s. 6d.‡
200. *FUEL*, its Combustion and Economy. By C. W. WILLIAMS. With Recent Practice in the Combustion and Economy of Fuel—Coal, Coke, Wood, Peat, Petroleum, &c.—by D. K. CLARK, M.I.C.E. 3s. 6d.‡
202. *LOCOMOTIVE ENGINES*. By G. D. DEMPSEY, C.E.; with large additions by D. KINNEAR CLARK, M.I.C.E. 3s.‡
211. *THE BOILERMAKER'S ASSISTANT* in Drawing, Templating, and Calculating Boiler and Tank Work. By JOHN COURTNEY, Practical Boiler Maker. Edited by D. K. CLARK, C.E. 100 Illustrations. 2s.
217. *SEWING MACHINERY:* Its Construction, History, &c., with full Technical Directions for Adjusting, &c. By J. W. URQUHART, C.E. 2s.‡
223. *MECHANICAL ENGINEERING*. Comprising Metallurgy, Moulding, Casting, Forging, Tools, Workshop Machinery, Manufacture of the Steam Engine, &c. By FRANCIS CAMPIN, C.E. Second Edition. 2s. 6d.‡
236. *DETAILS OF MACHINERY*. Comprising Instructions for the Execution of various Works in Iron. By FRANCIS CAMPIN, C.E. 3s.‡
237. *THE SMITHY AND FORGE;* including the Farrier's Art and Coach Smithing. By W. J. E. CRANE. Illustrated. 2s. 6d.‡
238. *THE SHEET-METAL WORKER'S GUIDE;* a Practical Handbook for Tinsmiths, Coppersmiths, Zincworkers, &c. With 94 Diagrams and Working Patterns. By W. J. E. CRANE. Third Edition, revised. 1s. 6d.
251. *STEAM AND MACHINERY MANAGEMENT:* with Hints on Construction and Selection. By M. POWIS BALE, M.I.M.E. 2s. 6d.‡
254. *THE BOILERMAKER'S READY-RECKONER*. By J. COURTNEY. Edited by D. K. CLARK, C.E. 4s.

*** *Nos.* 211 *and* 254 *in One Vol., half-bound, entitled* "THE BOILERMAKER'S READY-RECKONER AND ASSISTANT." By J. COURTNEY and D. K. CLARK. 7s.

255. *LOCOMOTIVE ENGINE-DRIVING*. A Practical Manual for Engineers in charge of Locomotive Engines. By MICHAEL REYNOLDS, M.S.E. Ninth Edition. 3s. 6d., limp; 4s. 6d. cloth boards.
256. *STATIONARY ENGINE-DRIVING*. A Practical Manual for Engineers in charge of Stationary Engines. By MICHAEL REYNOLDS, M.S.E. Fourth Edition. 3s. 6d. limp; 4s. 6d. cloth boards.
260. *IRON BRIDGES OF MODERATE SPAN:* their Construction and Erection. By HAMILTON W. PENDRED, C.E. 2s.

☞ *The* ‡ *indicates that these vols. may be had strongly bound at* 6*d. extra.*

MINING, METALLURGY, ETC.

4. *MINERALOGY*, Rudiments of; a concise View of the General Properties of Minerals. By A. RAMSAY, F.G.S., F.R.G.S., &c. Fourth Edition, revised and enlarged. Illustrated. 3s. 6d.‡

117. *SUBTERRANEOUS SURVEYING*, with and without the Magnetic Needle. By T. FENWICK and T. BAKER, C.E. Illustrated. 2s. 6d.‡

135. *ELECTRO-METALLURGY;* Practically Treated. By ALEXANDER WATT. Tenth Edition, enlarged, with additional Illustrations, and including the most recent Processes. 3s. 6d.‡

172. *MINING TOOLS*, Manual of. For the Use of Mine Managers, Agents, Students, &c. By WILLIAM MORGANS. 2s. 6d.

172*. *MINING TOOLS, ATLAS* of Engravings to Illustrate the above, containing 235 Illustrations, drawn to Scale. 4to. 4s. 6d.

176. *METALLURGY OF IRON.* Containing History of Iron Manufacture, Methods of Assay, and Analyses of Iron Ores, Processes of Manufacture of Iron and Steel, &c. By H. BAUERMAN, F.G.S. Sixth Edition, revised and enlarged. 5s.‡

180. *COAL AND COAL MINING.* By the late Sir WARINGTON W. SMYTH, M.A., F.R.S. Seventh Edition, revised. 3s. 6d.‡

195. *THE MINERAL SURVEYOR AND VALUER'S COMPLETE GUIDE.* By W. LINTERN, M.E. Third Edition, including Magnetic and Angular Surveying. With Four Plates. 3s. 6d.‡

214. *SLATE AND SLATE QUARRYING*, Scientific, Practical, and Commercial. By D. C. DAVIES, F.G.S., Mining Engineer, &c. 3s.‡

264. *A FIRST BOOK OF MINING AND QUARRYING*, with the Sciences connected therewith, for Primary Schools and Self Instruction. By J. H. COLLINS, F.G.S. Second Edition, with additions. 1s. 6d.

ARCHITECTURE, BUILDING, ETC.

16. *ARCHITECTURE—ORDERS*—The Orders and their Æsthetic Principles. By W. H. LEEDS. Illustrated. 1s. 6d.

17. *ARCHITECTURE—STYLES*—The History and Description of the Styles of Architecture of Various Countries, from the Earliest to the Present Period. By T. TALBOT BURY, F.R.I.B.A., &c. Illustrated. 2s.

*** ORDERS AND STYLES OF ARCHITECTURE, *in One Vol., 3s. 6d.*

18. *ARCHITECTURE—DESIGN*—The Principles of Design in Architecture, as deducible from Nature and exemplified in the Works of the Greek and Gothic Architects. By E. L. GARBETT, Architect. Illustrated. 2s.6d.

*** *The three preceding Works, in One handsome Vol., half bound, entitled* "MODERN ARCHITECTURE," *price 6s.*

22. *THE ART OF BUILDING*, Rudiments of. General Principles of Construction, Materials used in Building, Strength and Use of Materials, Working Drawings, Specifications, and Estimates. By E. DOBSON, 2s.‡

25. *MASONRY AND STONECUTTING:* Rudimentary Treatise on the Principles of Masonic Projection and their application to Construction. By EDWARD DOBSON, M.R.I.B.A., &c. 2s. 6d.‡

42. *COTTAGE BUILDING.* By C. BRUCE ALLEN, Architect. Eleventh Edition, revised and enlarged. With a Chapter on Economic Cottages for Allotments, by EDWARD E. ALLEN, C.E. 2s.

45. *LIMES, CEMENTS, MORTARS, CONCRETES, MASTICS,* PLASTERING, &c. By G. R. BURNELL, C.E. Fourteenth Edition. 1s. 6d.

57. *WARMING AND VENTILATION.* An Exposition of the General Principles as applied to Domestic and Public Buildings, Mines, Lighthouses, Ships, &c. By C. TOMLINSON, F.R.S., &c. Illustrated. 3s.

111. *ARCHES, PIERS, BUTTRESSES, &c.:* Experimental Essays on the Principles of Construction. By W. BLAND. Illustrated. 1s. 6d

☞ *The ‡ indicates that these vols. may be had strongly bound at 6d. extra.*

Architecture, Building, etc., *continued.*

116. *THE ACOUSTICS OF PUBLIC BUILDINGS;* or, The Principles of the Science of Sound applied to the purposes of the Architect and Builder. By T. ROGER SMITH, M.R.I.B.A., Architect. Illustrated. 1s. 6d.

127. *ARCHITECTURAL MODELLING IN PAPER*, the Art of. By T. A. RICHARDSON, Architect. Illustrated. 1s. 6d.

128. *VITRUVIUS—THE ARCHITECTURE OF MARCUS VITRUVIUS POLLO.* In Ten Books. Translated from the Latin by JOSEPH GWILT, F.S.A., F.R.A.S. With 23 Plates. 5s.

130. *GRECIAN ARCHITECTURE*, An Inquiry into the Principles of Beauty in; with an Historical View of the Rise and Progress of the Art in Greece. By the EARL OF ABERDEEN. 1s.

*** *The two preceding Works in One handsome Vol., half bound, entitled* "ANCIENT ARCHITECTURE," *price* 6s.

132. *THE ERECTION OF DWELLING-HOUSES.* Illustrated by a Perspective View, Plans, Elevations, and Sections of a pair of Semi-detached Villas, with the Specification, Quantities, and Estimates, &c. By S. H. BROOKS. New Edition, with Plates. 2s. 6d ‡

156. *QUANTITIES & MEASUREMENTS* in Bricklayers', Masons', Plasterers', Plumbers', Painters', Paperhangers', Gilders', Smiths', Carpenters' and Joiners' Work. By A. C. BEATON, Surveyor. Ninth Edition. 1s. 6d.

175. *LOCKWOOD'S BUILDER'S PRICE BOOK FOR* 1895. A Comprehensive Handbook of the Latest Prices and Data for Builders, Architects, Engineers, and Contractors. Re-constructed, Re-written, and further Enlarged. By FRANCIS T. W. MILLER, A.R.I.B.A. 800 pages. 4s., cloth boards.

182. *CARPENTRY AND JOINERY*—THE ELEMENTARY PRINCIPLES OF CARPENTRY. Chiefly composed from the Standard Work of THOMAS TREDGOLD, C.E. With a TREATISE ON JOINERY by E. WYNDHAM TARN, M.A. Fifth Edition, Revised. 3s. 6d.‡

182*. *CARPENTRY AND JOINERY. ATLAS* of 35 Plates to accompany the above. With Descriptive Letterpress. 4to 6s.

185. *THE COMPLETE MEASURER;* the Measurement of Boards, Glass, &c.; Unequal-sided, Square-sided, Octagonal-sided, Round Timber and Stone, and Standing Timber, &c. By RICHARD HORTON. Fifth Edition. 4s.; strongly bound in leather, 5s.

187. *HINTS TO YOUNG ARCHITECTS.* By G. WIGHTWICK. New Edition. By G. H. GUILLAUME. Illustrated. 3s. 6d.‡

188. *HOUSE PAINTING, GRAINING, MARBLING, AND SIGN WRITING:* with a Course of Elementary Drawing for House-Painters, Sign-Writers, &c., and a Collection of Useful Receipts. By ELLIS A. DAVIDSON. Sixth Edition. With Coloured Plates. 5s. cloth limp; 6s. cloth boards.

189. *THE RUDIMENTS OF PRACTICAL BRICKLAYING.* In Six Sections: General Principles; Arch Drawing, Cutting, and Setting; Pointing; Paving, Tiling, Materials; Slating and Plastering; Practical Geometry, Mensuration, &c. By ADAM HAMMOND. Eighth Edition. 1s. 6d.

191. *PLUMBING.* A Text-Book to the Practice of the Art or Craft of the Plumber. With Chapters upon House Drainage and Ventilation. Sixth Edition. With 380 Illustrations. By W. P. BUCHAN. 3s. 6d.‡

192. *THE TIMBER IMPORTER'S, TIMBER MERCHANT'S,* and BUILDER'S STANDARD GUIDE. By R. E. GRANDY. 2s.

206. *A BOOK ON BUILDING, Civil and Ecclesiastical,* including CHURCH RESTORATION. With the Theory of Domes and the Great Pyramid, &c. By Sir EDMUND BECKETT, Bart., LL.D., Q.C., F.R.A.S. 4s. 6d.‡

226. *THE JOINTS MADE AND USED BY BUILDERS* in the Construction of various kinds of Engineering and Architectural Works. By WYVILL J. CHRISTY, Architect. With upwards of 160 Engravings on Wood. 3s.‡

228. *THE CONSTRUCTION OF ROOFS OF WOOD AND IRON.* By E. WYNDHAM TARN, M.A., Architect. Third Edition, revised. 1s. 6d.

☞ *The ‡ indicates that these vols. may be had strongly bound at 6d. extra.*

Architecture, Building, etc., *continued.*

229. *ELEMENTARY DECORATION:* as applied to the Interior and Exterior Decoration of Dwelling-Houses, &c. By J. W. FACEY. 2s.

257. *PRACTICAL HOUSE DECORATION.* A Guide to the Art of Ornamental Painting. By JAMES W. FACEY. 2s. 6d.

*** *The two preceding Works, in One handsome Vol., half-bound, entitled* "HOUSE DECORATION, ELEMENTARY AND PRACTICAL," *price* 5s.

230. *A PRACTICAL TREATISE ON HANDRAILING.* Showing New and Simple Methods. By G. COLLINGS. Second Edition, Revised, including A TREATISE ON STAIRBUILDING. Plates. 2s. 6d.

247. *BUILDING ESTATES:* a Rudimentary Treatise on the Development, Sale, Purchase, and General Management of Building Land. By FOWLER MAITLAND, Surveyor. Second Edition, revised. 2s.

248. *PORTLAND CEMENT FOR USERS.* By HENRY FAIJA, Assoc. M. Inst. C.E. Third Edition, corrected. Illustrated. 2s.

252. *BRICKWORK:* a Practical Treatise, embodying the General and Higher Principles of Bricklaying, Cutting and Setting, &c. By F. WALKER. Third Edition, Revised and Enlarged. 1s. 6d.

23. *THE PRACTICAL BRICK AND TILE BOOK.* Comprising:
189. BRICK AND TILE MAKING, by E. DOBSON, A.I.C.E.; PRACTICAL BRICKLAY-
265. ING, by A. HAMMOND; BRICKCUTTING AND SETTING, by A. HAMMOND. 534 pp. with 270 Illustrations. 6s. Strongly half-bound.

253. *THE TIMBER MERCHANT'S, SAW-MILLER'S, AND* IMPORTER'S FREIGHT-BOOK AND ASSISTANT. By WM. RICHARDSON. With Additions by M. POWIS BALE, A.M.Inst.C.E. 3s.‡

258. *CIRCULAR WORK IN CARPENTRY AND JOINERY.* A Practical Treatise on Circular Work of Single and Double Curvature. By GEORGE COLLINGS. Second Edition, 2s. 6d.

259. *GAS FITTING:* A Practical Handbook treating of every Description of Gas Laying and Fitting. By JOHN BLACK. 2s. 6d.‡

261. *SHORING AND ITS APPLICATION:* A Handbook for the Use of Students. By GEORGE H. BLAGROVE. 1s. 6d.

265. *THE ART OF PRACTICAL BRICK CUTTING & SETTING.* By ADAM HAMMOND. With 90 Engravings. 1s. 6d.

267. *THE SCIENCE OF BUILDING:* An Elementary Treatise on the Principles of Construction. By E. WYNDHAM TARN, M.A. Lond. Third Edition, Revised and Enlarged. 3s. 6d.‡

271. *VENTILATION:* a Text-book to the Practice of the Art of Ventilating Buildings. By W. P. BUCHAN, R.P., Sanitary Engineer, Author of "Plumbing," &c. 3s. 6d.‡

272. *ROOF CARPENTRY;* Practical Lessons in the Framing of Wood Roofs. For the Use of Working Carpenters. By GEO. COLLINGS, Author of "Handrailing and Stairbuilding," &c. 2s.

273. *THE PRACTICAL PLASTERER:* A Compendium of Plain and Ornamental Plaster Work. By WILFRED KEMP. 2s. [*Just published.*

SHIPBUILDING, NAVIGATION, ETC.

51. *NAVAL ARCHITECTURE.* An Exposition of the Elementary Principles. By J. PEAKE. Fifth Edition, with Plates. 3s. 6d.‡

53*. *SHIPS FOR OCEAN & RIVER SERVICE,* Elementary and Practical Principles of the Construction of. By H. A. SOMMERFELDT. 1s. 6d.

53**. *AN ATLAS OF ENGRAVINGS* to Illustrate the above. Twelve large folding plates. Royal 4to, cloth. 7s. 6d.

54. *MASTING, MAST-MAKING, AND RIGGING OF SHIPS,* Also Tables of Spars, Rigging, Blocks; Chain, Wire, and Hemp Ropes, &c., relative to every class of vessels. By ROBERT KIPPING, N.A. 2s.

☞ *The ‡ indicates that these vols. may be had strongly bound at 6d. extra.*

Shipbuilding, Navigation, Marine Engineering, etc., *cont.*

54*. *IRON SHIP-BUILDING.* With Practical Examples and Details. By JOHN GRANTHAM, C.E. Fifth Edition. 4s.

55. *THE SAILOR'S SEA BOOK:* a Rudimentary Treatise on Navigation. By JAMES GREENWOOD, B.A. With numerous Woodcuts and Coloured Plates. New and enlarged edition. By W. H. ROSSER. 2s. 6d.‡

80. *MARINE ENGINES AND STEAM VESSELS.* By ROBERT MURRAY, C.E. Eighth Edition, thoroughly Revised, with Additions by the Author and by GEORGE CARLISLE, C.E. 4s. 6d. limp; 5s. cloth boards.

83*bis*. *THE FORMS OF SHIPS AND BOATS.* By W. BLAND. Ninth Edition, with numerous Illustrations and Models. 1s. 6d.

99. *NAVIGATION AND NAUTICAL ASTRONOMY*, in Theory and Practice. By Prof. J. R. YOUNG. New Edition. 2s. 6d.

106. *SHIPS' ANCHORS*, a Treatise on. By G. COTSELL, N.A. 1s. 6d.

149. *SAILS AND SAIL-MAKING.* With Draughting, and the Centre of Effort of the Sails; Weights and Sizes of Ropes; Masting, Rigging, and Sails of Steam Vessels, &c. 13th Edition. By R. KIPPING, N.A., 2s. 6d.‡

155. *ENGINEER'S GUIDE TO THE ROYAL & MERCANTILE* NAVIES. By a PRACTICAL ENGINEER. Revised by D. F. M'CARTHY. 3s.

55 & 204. *PRACTICAL NAVIGATION.* Consisting of The Sailor's Sea-Book. By JAMES GREENWOOD and W. H. ROSSER. Together with the requisite Mathematical and Nautical Tables for the Working of the Problems. By H. LAW, C.E., and Prof. J. R. YOUNG. 7s. Half-bound.

AGRICULTURE, GARDENING, ETC.

61*. *A COMPLETE READY RECKONER FOR THE ADMEASUREMENT OF LAND*, &c. By A. ARMAN. Fourth Edition, revised and extended by C. NORRIS, Surveyor, Valuer, &c. 2s.

131. *MILLER'S, CORN MERCHANT'S, AND FARMER'S* READY RECKONER. Second Edition, with a Price List of Modern Flour-Mill Machinery, by W. S. HUTTON, C.E. 2s.

140. *SOILS, MANURES, AND CROPS.* (Vol. 1. OUTLINES OF MODERN FARMING.) By R. SCOTT BURN. Woodcuts. 2s.

141. *FARMING & FARMING ECONOMY*, Notes, Historical and Practical, on. (Vol. 2. OUTLINES OF MODERN FARMING.) By R. SCOTT BURN. 3s.

142. *STOCK; CATTLE, SHEEP, AND HORSES.* (Vol. 3. OUTLINES OF MODERN FARMING.) By R. SCOTT BURN. Woodcuts. 2s. 6d.

145. *DAIRY, PIGS, AND POULTRY*, Management of the. By R. SCOTT BURN. (Vol. 4. OUTLINES OF MODERN FARMING.) 2s.

146. *UTILIZATION OF SEWAGE, IRRIGATION, AND* RECLAMATION OF WASTE LAND. (Vol. 5. OUTLINES OF MODERN FARMING.) By R. SCOTT BURN. Woodcuts. 2s. 6d.

*** *Nos.* 140-1-2-5-6, *in One Vol., handsomely half-bound, entitled* "OUTLINES OF MODERN FARMING." By ROBERT SCOTT BURN. *Price* 12s.

177. *FRUIT TREES*, The Scientific and Profitable Culture of. From the French of DU BREUIL. Revised by GEO. GLENNY. 187 Woodcuts. 3s. 6d.‡

198. *SHEEP; THE HISTORY, STRUCTURE, ECONOMY, AND* DISEASES OF. By W. C. SPOONER, M.R.V.C., &c. Fifth Edition, enlarged, including Specimens of New and Improved Breeds. 3s. 6d.‡

201. *KITCHEN GARDENING MADE EASY.* By GEORGE M. F. GLENNY. Illustrated. 1s. 6d.‡

207. *OUTLINES OF FARM MANAGEMENT, and the Organization of Farm Labour.* By R. SCOTT BURN. 2s. 6d.‡

208. *OUTLINES OF LANDED ESTATES MANAGEMENT.* By R. SCOTT BURN. 2s. 6d.

*** *Nos.* 207 & 208 *in One Vol., handsomely half-bound, entitled* "OUTLINES OF LANDED ESTATES AND FARM MANAGEMENT." By R. SCOTT BURN. *Price* 6s.

☞ *The ‡ indicates that these vols. may be had strongly bound at 6d. extra.*

Agriculture, Gardening, etc., *continued.*

209. *THE TREE PLANTER AND PLANT PROPAGATOR.* A Practical Manual on the Propagation of Forest Trees, Fruit Trees, Flowering Shrubs, Flowering Plants, &c. By SAMUEL WOOD. 2s.

210. *THE TREE PRUNER.* A Practical Manual on the Pruning of Fruit Trees, including also their Training and Renovation; also the Pruning of Shrubs, Climbers, and Flowering Plants. By SAMUEL WOOD. 1s. 6d.

*** *Nos.* 209 *&* 210 *in One Vol., handsomely half-bound, entitled* "THE TREE PLANTER, PROPAGATOR, AND PRUNER." By SAMUEL WOOD. *Price* 3s. 6d.

218. *THE HAY AND STRAW MEASURER:* Being New Tables for the Use of Auctioneers, Valuers, Farmers, Hay and Straw Dealers, &c. By JOHN STEELE. Fifth Edition. 2s.

222. *SUBURBAN FARMING.* The Laying-out and Cultivation of Farms, adapted to the Produce of Milk, Butter, and Cheese, Eggs, Poultry, and Pigs. By Prof. JOHN DONALDSON and R. SCOTT BURN. 3s. 6d.‡

231. *THE ART OF GRAFTING AND BUDDING.* By CHARLES BALTET. With Illustrations. 2s. 6d.‡

232. *COTTAGE GARDENING;* or, Flowers, Fruits, and Vegetables for Small Gardens. By E. HOBDAY. 1s. 6d.

233. *GARDEN RECEIPTS.* Edited by CHARLES W. QUIN. 1s. 6d.

234. *MARKET AND KITCHEN GARDENING.* By C. W. SHAW, late Editor of "Gardening Illustrated." 3s.‡

239. *DRAINING AND EMBANKING.* A Practical Treatise, embodying the most recent experience in the Application of Improved Methods. By JOHN SCOTT, late Professor of Agriculture and Rural Economy at the Royal Agricultural College, Cirencester. With 68 Illustrations. 1s. 6d.

240. *IRRIGATION AND WATER SUPPLY.* A Treatise on Water Meadows, Sewage Irrigation, and Warping; the Construction of Wells, Ponds, and Reservoirs, &c. By Prof. JOHN SCOTT. With 34 Illus. 1s. 6d.

241. *FARM ROADS, FENCES, AND GATES.* A Practical Treatise on the Roads, Tramways, and Waterways of the Farm; the Principles of Enclosures; and the different kinds of Fences, Gates, and Stiles. By Professor JOHN SCOTT. With 75 Illustrations. 1s. 6d.

242. *FARM BUILDINGS.* A Practical Treatise on the Buildings necessary for various kinds of Farms, their Arrangement and Construction, with Plans and Estimates. By Prof. JOHN SCOTT. With 105 Illus. 2s.

243. *BARN IMPLEMENTS AND MACHINES.* A Practical Treatise on the Application of Power to the Operations of Agriculture; and on various Machines used in the Threshing-barn, in the Stock-yard, and in the Dairy, &c. By Prof. J. SCOTT. With 123 Illustrations. 2s.

244. *FIELD IMPLEMENTS AND MACHINES.* A Practical Treatise on the Varieties now in use, with Principles and Details of Construction, their Points of Excellence, and Management. By Professor JOHN SCOTT. With 138 Illustrations. 2s.

245. *AGRICULTURAL SURVEYING.* A Practical Treatise on Land Surveying, Levelling, and Setting-out; and on Measuring and Estimating Quantities, Weights, and Values of Materials, Produce, Stock, &c. By Prof. JOHN SCOTT. With 62 Illustrations. 1s. 6d.

*** *Nos.* 239 *to* 245 *in One Vol., handsomely half-bound, entitled* "THE COMPLETE TEXT-BOOK OF FARM ENGINEERING." By Professor JOHN SCOTT. *Price* 12s.

250. *MEAT PRODUCTION.* A Manual for Producers, Distributors, &c. By JOHN EWART. 2s. 6d.‡

266. *BOOK-KEEPING FOR FARMERS & ESTATE OWNERS.* By J. M. WOODMAN, Chartered Accountant. 2s. 6d. cloth limp; 3s. 6d. cloth boards.

☞ *The* ‡ *indicates that these vols. may be had strongly bound at* 6d. *extra.*

MATHEMATICS, ARITHMETIC, ETC.

32. *MATHEMATICAL INSTRUMENTS*, a Treatise on; Their Construction, Adjustment, Testing, and Use concisely Explained. By J. F. HEATHER, M.A. Fourteenth Edition, revised, with additions, by A. T. WALMISLEY, M.I.C.E., Fellow of the Surveyors' Institution. Original Edition, in 1 vol., Illustrated. 2s.‡

*** *In ordering the above, be careful to say, "Original Edition" (No. 32), to distinguish it from the Enlarged Edition in 3 vols. (Nos. 168-9-70.)*

76. *DESCRIPTIVE GEOMETRY*, an Elementary Treatise on; with a Theory of Shadows and of Perspective, extracted from the French of G. MONGE. To which is added, a description of the Principles and Practice of Isometrical Projection. By J. F. HEATHER, M.A. With 14 Plates. 2s.

178. *PRACTICAL PLANE GEOMETRY:* giving the Simplest Modes of Constructing Figures contained in one Plane and Geometrical Construction of the Ground. By J. F. HEATHER, M.A. With 215 Woodcuts. 2s.

83. *COMMERCIAL BOOK-KEEPING*. With Commercial Phrases and Forms in English, French, Italian, and German. By JAMES HADDON, M.A., Arithmetical Master of King's College School, London. 1s. 6d.

84. *ARITHMETIC*, a Rudimentary Treatise on: with full Explanations of its Theoretical Principles, and numerous Examples for Practice. By Professor J. R. YOUNG. Twelfth Edition. 1s. 6d.

84*. A KEY to the above, containing Solutions in full to the Exercises, together with Comments, Explanations, and Improved Processes, for the Use of Teachers and Unassisted Learners. By J. R. YOUNG. 1s. 6d.

85. *EQUATIONAL ARITHMETIC*, applied to Questions of Interest, Annuities, Life Assurance, and General Commerce; with various Tables by which all Calculations may be greatly facilitated. By W. HIPSLEY. 2s.

86. *ALGEBRA*, the Elements of. By JAMES HADDON, M.A. With Appendix, containing miscellaneous Investigations, and a Collection of Problems in various parts of Algebra. 2s.

86*. A KEY AND COMPANION to the above Book, forming an extensive repository of Solved Examples and Problems in Illustration of the various Expedients necessary in Algebraical Operations. By J. R. YOUNG. 1s. 6d.

88. *EUCLID*, THE ELEMENTS OF: with many additional Propositions
89. and Explanatory Notes: to which is prefixed, an Introductory Essay on Logic. By HENRY LAW, C.E. 2s. 6d.‡

*** *Sold also separately, viz.:—*

88. EUCLID, The First Three Books. By HENRY LAW, C.E. 1s. 6d.
89. EUCLID, Books 4, 5, 6, 11, 12. By HENRY LAW, C.E. 1s. 6d.

90. *ANALYTICAL GEOMETRY AND CONIC SECTIONS*, By JAMES HANN. A New Edition, by Professor J. R. YOUNG. 2s.‡

91. *PLANE TRIGONOMETRY*, the Elements of. By JAMES HANN, formerly Mathematical Master of King's College, London. 1s. 6d.

92. *SPHERICAL TRIGONOMETRY*, the Elements of. By JAMES HANN. Revised by CHARLES H. DOWLING, C.E. 1s.

*** *Or with "The Elements of Plane Trigonometry," in One Volume, 2s.* 6d.

93. *MENSURATION AND MEASURING*. With the Mensuration and Levelling of Land for the Purposes of Modern Engineering. By T. BAKER, C.E. New Edition by E. NUGENT, C.E. Illustrated. 1s. 6d.

101. *DIFFERENTIAL CALCULUS*, Elements of the. By W. S. B. WOOLHOUSE, F.R.A.S., &c. 1s. 6d.

102. *INTEGRAL CALCULUS*, Rudimentary Treatise on the. By HOMERSHAM COX, B.A. Illustrated. 1s.

136. *ARITHMETIC*, Rudimentary, for the Use of Schools and Self-Instruction. By JAMES HADDON, M.A. Revised by A. ARMAN. 1s. 6d.

137. A KEY TO HADDON'S RUDIMENTARY ARITHMETIC. By A. ARMAN. 1s. 6d.

☞ *The ‡ indicates that these vols. may be had strongly bound at 6d. extra.*

Mathematics, Arithmetic, etc., *continued.*

168. *DRAWING AND MEASURING INSTRUMENTS.* Including—I. Instruments employed in Geometrical and Mechanical Drawing, and in the Construction, Copying, and Measurement of Maps and Plans. II. Instruments used for the purposes of Accurate Measurement, and for Arithmetical Computations. By J. F. HEATHER, M.A. Illustrated. 1s. 6d

169. *OPTICAL INSTRUMENTS.* Including (more especially) Telescopes, Microscopes, and Apparatus for producing copies of Maps and Plans by Photography. By J. F. HEATHER, M.A. Illustrated. 1s. 6d.

170. *SURVEYING AND ASTRONOMICAL INSTRUMENTS.* Including—I. Instruments Used for Determining the Geometrical Features of a portion of Ground. II. Instruments Employed in Astronomical Observations. By J. F. HEATHER, M.A. Illustrated. 1s. 6d.

*** *The above three volumes form an enlargement of the Author's original work "Mathematical Instruments." (See No. 32 in the Series.)*

168.
169.
170. } *MATHEMATICAL INSTRUMENTS.* By J. F. HEATHER, M.A. Enlarged Edition, for the most part entirely re-written. The 3 Parts as above, in One thick Volume. With numerous Illustrations. 4s. 6d.‡

158. *THE SLIDE RULE, AND HOW TO USE IT;* containing full, easy, and simple Instructions to perform all Business Calculations with unexampled rapidity and accuracy. By CHARLES HOARE, C.E. Sixth Edition. With a Slide Rule in tuck of cover. 2s. 6d.‡

196. *THEORY OF COMPOUND INTEREST AND ANNUITIES;* with Tables of Logarithms for the more Difficult Computations of Interest, Discount, Annuities, &c. By FÉDOR THOMAN. Fourth Edition. 4s.‡

199. *THE COMPENDIOUS CALCULATOR;* or, Easy and Concise Methods of Performing the various Arithmetical Operations required in Commercial and Business Transactions; together with Useful Tables. By D. O'GORMAN. Twenty-seventh Edition, carefully revised by C. NORRIS. 2s. 6d., cloth limp; 3s. 6d., strongly half-bound in leather.

204. *MATHEMATICAL TABLES,* for Trigonometrical, Astronomical, and Nautical Calculations; to which is prefixed a Treatise on Logarithms. By HENRY LAW, C.E. Together with a Series of Tables for Navigation and Nautical Astronomy. By Prof. J. R. YOUNG. New Edition. 4s.

204*. *LOGARITHMS.* With Mathematical Tables for Trigonometrical, Astronomical, and Nautical Calculations. By HENRY LAW, M.Inst.C.E. New and Revised Edition. (Forming part of the above Work). 3s.

221. *MEASURES, WEIGHTS, AND MONEYS OF ALL NATIONS,* and an Analysis of the Christian, Hebrew, and Mahometan Calendars. By W. S. B. WOOLHOUSE, F.R.A.S., F.S.S. Seventh Edition, 2s. 6d.‡

227. *MATHEMATICS AS APPLIED TO THE CONSTRUCTIVE ARTS.* Illustrating the various processes of Mathematical Investigation, by means of Arithmetical and Simple Algebraical Equations and Practical Examples. By FRANCIS CAMPIN, C.E. Third Edition. 3s.‡

PHYSICAL SCIENCE, NATURAL PHILOSOPHY, ETC.

1. *CHEMISTRY.* By Professor GEORGE FOWNES, F.R.S. With an Appendix on the Application of Chemistry to Agriculture. 1s.

2. *NATURAL PHILOSOPHY,* Introduction to the Study of. By C. TOMLINSON. Woodcuts. 1s. 6d.

6. *MECHANICS,* Rudimentary Treatise on. By CHARLES TOMLINSON. Illustrated. 1s. 6d.

7. *ELECTRICITY;* showing the General Principles of Electrical Science, and the purposes to which it has been applied. By Sir W. SNOW HARRIS, F.R.S., &c. With Additions by R. SABINE, C.E., F.S.A. 1s. 6d.

7*. *GALVANISM.* By Sir W. SNOW HARRIS. New Edition by ROBERT SABINE, C.E., F.S.A. 1s. 6d.

8. *MAGNETISM;* being a concise Exposition of the General Principles of Magnetical Science. By Sir W. SNOW HARRIS. New Edition, revised by H. M. NOAD, Ph.D. With 165 Woodcuts. 3s. 6d.‡

☞ *The ‡ indicates that these vols. may be had strongly bound at 6d. extra.*

Physical Science, Natural Philosophy, etc., *continued.*

11. *THE ELECTRIC TELEGRAPH;* its History and Progress; with Descriptions of some of the Apparatus. By R. SABINE, C.E., F.S.A. 3s.
12. *PNEUMATICS,* including Acoustics and the Phenomena of Wind Currents, for the Use of Beginners By CHARLES TOMLINSON, F.R.S. Fourth Edition, enlarged. Illustrated. 1s. 6d.
72. *MANUAL OF THE MOLLUSCA;* a Treatise on Recent and Fossil Shells. By Dr. S. P. WOODWARD, A.L.S. Fourth Edition. With Plates and 300 Woodcuts. 7s. 6d., cloth.
96. *ASTRONOMY.* By the late Rev. ROBERT MAIN, M.A. Third Edition, by WILLIAM THYNNE LYNN, B.A., F.R.A.S. 2s.
97. *STATICS AND DYNAMICS,* the Principles and Practice of; embracing also a clear development of Hydrostatics, Hydrodynamics, and Central Forces. By T. BAKER, C.E. Fourth Edition. 1s. 6d.
173. *PHYSICAL GEOLOGY,* partly based on Major-General PORTLOCK'S "Rudiments of Geology." By RALPH TATE, A.L.S., &c. Woodcuts. 2s.
174. *HISTORICAL GEOLOGY,* partly based on Major-General PORTLOCK'S "Rudiments." By RALPH TATE, A.L.S., &c. Woodcuts. 2s. 6d.
173 & 174. *RUDIMENTARY TREATISE ON GEOLOGY,* Physical and Historical. Partly based on Major-General PORTLOCK'S "Rudiments of Geology." By RALPH TATE, A.L.S., F.G.S., &c. In One Volume. 4s. 6d.‡
183 & 184. *ANIMAL PHYSICS,* Handbook of. By Dr. LARDNER, D.C.L., formerly Professor of Natural Philosophy and Astronomy in University College, Lond. With 520 Illustrations. In One Vol. 7s. 6d., cloth boards.

*** *Sold also in Two Parts, as follows :—*

183. ANIMAL PHYSICS. By Dr. LARDNER. Part I., Chapters I.—VII. 4s.
184. ANIMAL PHYSICS. By Dr. LARDNER. Part II., Chapters VIII.—XVIII. 3s.

269. *LIGHT:* an Introduction to the Science of Optics, for the Use of Students of Architecture, Engineering, and other Applied Sciences. By E. WYNDHAM TARN, M.A. 1s. 6d.

FINE ARTS.

20. *PERSPECTIVE FOR BEGINNERS.* Adapted to Young Students and Amateurs in Architecture, Painting, &c. By GEORGE PYNE. 2s.
40 *GLASS STAINING, AND THE ART OF PAINTING ON GLASS.* From the German of Dr. GESSERT and EMANUEL OTTO FROMBERG. With an Appendix on THE ART OF ENAMELLING. 2s. 6d.
69. *MUSIC,* A Rudimentary and Practical Treatise on. With numerous Examples. By CHARLES CHILD SPENCER. 2s. 6d.
71. *PIANOFORTE,* The Art of Playing the. With numerous Exercises & Lessons from the Best Masters. By CHARLES CHILD SPENCER. 1s.6d.
69-71. *MUSIC & THE PIANOFORTE.* In one vol. Half bound, 5s.
181. *PAINTING POPULARLY EXPLAINED,* including Fresco, Oil, Mosaic, Water Colour, Water-Glass, Tempera, Encaustic, Miniature, Painting on Ivory, Vellum, Pottery, Enamel, Glass, &c. With Historical Sketches of the Progress of the Art by THOMAS JOHN GULLICK, assisted by JOHN TIMBS, F.S.A. Sixth Edition, revised and enlarged. 5s.‡
186. *A GRAMMAR OF COLOURING,* applied to Decorative Painting and the Arts. By GEORGE FIELD. New Edition, enlarged and adapted to the Use of the Ornamental Painter and Designer. By ELLIS A. DAVIDSON. With two new Coloured Diagrams, &c. 3s.‡
246. *A DICTIONARY OF PAINTERS, AND HANDBOOK FOR* PICTURE AMATEURS; including Methods of Painting, Cleaning, Relining and Restoring, Schools of Painting, &c. With Notes on the Copyists and Imitators of each Master. By PHILIPPE DARYL. 2s. 6d.‡

☞ *The ‡ indicates that these vols. may be had strongly bound at 6d. extra.*

INDUSTRIAL AND USEFUL ARTS.

23. *BRICKS AND TILES*, Rudimentary Treatise on the Manufacture of. By E. DOBSON, M.R.I.B.A. Illustrated, 3s.‡

67. *CLOCKS, WATCHES, AND BELLS*, a Rudimentary Treatise on. By Sir EDMUND BECKETT, LL.D., Q.C. Seventh Edition, revised and enlarged. 4s. 6d. limp; 5s. 6d. cloth boards.

83**. *CONSTRUCTION OF DOOR LOCKS.* Compiled from the Papers of A. C. HOBBS, and Edited by CHARLES TOMLINSON, F.R.S. 2s. 6d.

162. *THE BRASS FOUNDER'S MANUAL;* Instructions for Modelling, Pattern-Making, Moulding, Turning, Filing, Burnishing, Bronzing, &c. With copious Receipts, &c. By WALTER GRAHAM. 2s.‡

205. *THE ART OF LETTER PAINTING MADE EASY.* By J. G. BADENOCH. Illustrated with 12 full-page Engravings of Examples. 1s. 6d.

215. *THE GOLDSMITH'S HANDBOOK*, containing full Instructions for the Alloying and Working of Gold. By GEORGE E. GEE, 3s.‡

225. *THE SILVERSMITH'S HANDBOOK*, containing full Instructions for the Alloying and Working of Silver. By GEORGE E. GEE. 3s.‡

*** *The two preceding Works, in One handsome Vol., half-bound, entitled* "THE GOLDSMITH'S & SILVERSMITH'S COMPLETE HANDBOOK," 7s.

249. *THE HALL-MARKING OF JEWELLERY PRACTICALLY CONSIDERED.* By GEORGE E. GEE. 3s.‡

224. *COACH BUILDING*, A Practical Treatise, Historical and Descriptive. By J. W. BURGESS. 2s. 6d.‡

235. *PRACTICAL ORGAN BUILDING.* By W. E. DICKSON, M.A., Precentor of Ely Cathedral. Illustrated. 2s. 6d.‡

262. *THE ART OF BOOT AND SHOEMAKING.* By JOHN BEDFORD LENO. Numerous Illustrations. Third Edition. 2s.

263. *MECHANICAL DENTISTRY:* A Practical Treatise on the Construction of the Various Kinds of Artificial Dentures, with Formulæ, Tables, Receipts, &c. By CHARLES HUNTER. Third Edition. 3s.‡

270. *WOOD ENGRAVING:* A Practical and Easy Introduction to the Study of the Art. By W. N. BROWN. 1s. 6d.

MISCELLANEOUS VOLUMES.

36. *A DICTIONARY OF TERMS used in ARCHITECTURE, BUILDING, ENGINEERING, MINING, METALLURGY, ARCHÆOLOGY, the FINE ARTS, &c.* By JOHN WEALE. Sixth Edition. Revised by ROBERT HUNT, F.R.S. Illustrated. 5s. limp; 6s. cloth boards.

50. *LABOUR CONTRACTS.* A Popular Handbook on the Law of Contracts for Works and Services. By DAVID GIBBONS. Fourth Edition, Revised, with Appendix of Statutes by T. F. UTTLEY, Solicitor, 3s. 6d. cloth.

112. *MANUAL OF DOMESTIC MEDICINE.* By R. GOODING, B.A., M.D. A Family Guide in all Cases of Accident and Emergency 2s.

112*. *MANAGEMENT OF HEALTH.* A Manual of Home and Personal Hygiene. By the Rev. JAMES BAIRD, B.A. 1s.

150. *LOGIC*, Pure and Applied. By S. H. EMMENS. 1s. 6d.

153. *SELECTIONS FROM LOCKE'S ESSAYS ON THE HUMAN UNDERSTANDING.* With Notes by S. H. EMMENS. 1s. 6d.

154. *GENERAL HINTS TO EMIGRANTS.* 2s.

157. *THE EMIGRANT'S GUIDE TO NATAL.* By R. MANN. 2s.

193. *HANDBOOK OF FIELD FORTIFICATION.* By Major W. W. KNOLLYS, F.R.G.S. With 163 Woodcuts. 3s.‡

194. *THE HOUSE MANAGER:* Being a Guide to Housekeeping, Practical Cookery, Pickling and Preserving, Household Work, Dairy Management, &c. By AN OLD HOUSEKEEPER. 3s. 6d.‡

194, 112 & 112*. *HOUSE BOOK (The).* Comprising:—I. THE HOUSE MANAGER. By an OLD HOUSEKEEPER. II. DOMESTIC MEDICINE. By R. GOODING, M.D. III. MANAGEMENT OF HEALTH. By J. BAIRD. In One Vol., half-bound, 6s.

☞ *The ‡ indicates that these vols may be had strongly bound at 6d. extra.*

EDUCATIONAL AND CLASSICAL SERIES.

HISTORY.

1. **England, Outlines of the History of;** more especially with reference to the Origin and Progress of the English Constitution. By WILLIAM DOUGLAS HAMILTON, F.S.A., of Her Majesty's Public Record Office. 4th Edition, revised. 5s.; cloth boards, 6s.

5. **Greece, Outlines of the History of;** in connection with the Rise of the Arts and Civilization in Europe. By W. DOUGLAS HAMILTON, of University College, London, and EDWARD LEVIEN, M.A., of Balliol College, Oxford. 2s. 6d.; cloth boards, 3s. 6d.

7. **Rome, Outlines of the History of:** from the Earliest Period to the Christian Era and the Commencement of the Decline of the Empire. By EDWARD LEVIEN, of Balliol College, Oxford. Map, 2s. 6d.; cl. bds. 3s. 6d.

9. **Chronology of History, Art, Literature, and Progress,** from the Creation of the World to the Present Time. The Continuation by W. D. HAMILTON, F.S.A. 3s.; cloth boards, 3s. 6d.

ENGLISH LANGUAGE AND MISCELLANEOUS.

11. **Grammar of the English Tongue,** Spoken and Written. With an Introduction to the Study of Comparative Philology. By HYDE CLARKE, D.C.L. Fifth Edition. 1s. 6d.

12. **Dictionary of the English Language,** as Spoken and Written. Containing above 100,000 Words. By HYDE CLARKE, D.C.L. 3s. 6d.; cloth boards, 4s. 6d.; complete with the GRAMMAR, cloth bds., 5s. 6d.

48. **Composition and Punctuation,** familiarly Explained for those who have neglected the Study of Grammar. By JUSTIN BRENAN. 18th Edition. 1s. 6d.

49. **Derivative Spelling-Book:** Giving the Origin of Every Word from the Greek, Latin, Saxon, German, Teutonic, Dutch, French, Spanish, and other Languages; with their present Acceptation and Pronunciation. By J. ROWBOTHAM, F.R.A.S. Improved Edition. 1s. 6d.

51. **The Art of Extempore Speaking:** Hints for the Pulpit, the Senate, and the Bar. By M. BAUTAIN, Vicar-General and Professor at the Sorbonne. Translated from the French. 8th Edition, carefully corrected. 2s. 6d.

53. **Places and Facts in Political and Physical Geography,** for Candidates in Examinations. By the Rev. EDGAR RAND, B.A. 1s.

54. **Analytical Chemistry,** Qualitative and Quantitative, a Course of. To which is prefixed, a Brief Treatise upon Modern Chemical Nomenclature and Notation. By WM. W. PINK and GEORGE E. WEBSTER. 2s.

THE SCHOOL MANAGERS' SERIES OF READING BOOKS,

Edited by the Rev. A. R. GRANT, Rector of Hitcham, and Honorary Canon of Ely; formerly H.M. Inspector of Schools.

LESSONS FROM THE BIBLE. Part I. Old Testament. 1s.

LESSONS FROM THE BIBLE. Part II. New Testament, to which is added THE GEOGRAPHY OF THE BIBLE, for very young Children. By Rev. C. THORNTON FORSTER. 1s. 2d. *** Or the Two Parts in One Volume. 2s.

FRENCH.

24. French Grammar. With Complete and Concise Rules on the Genders of French Nouns. By G. L. STRAUSS, Ph.D. 1s. 6d.
25. French-English Dictionary. Comprising a large number of New Terms used in Engineering, Mining, &c. By ALFRED ELWES. 1s. 6d.
26. English-French Dictionary. By ALFRED ELWES. 2s.
25,26. French Dictionary (as above). Complete, in One Vol., 3s.; cloth boards, 3s. 6d. *** Or with the GRAMMAR, cloth boards, 4s. 6d.
47. French and English Phrase Book: containing Introductory Lessons, with Translations, several Vocabularies of Words, a Collection of suitable Phrases, and Easy Familiar Dialogues. 1s. 6d.

GERMAN.

39. German Grammar. Adapted for English Students, from Heyse's Theoretical and Practical Grammar, by Dr. G. L. STRAUSS. 1s. 6d.
40. German Reader: A Series of Extracts, carefully culled from the most approved Authors of Germany; with Notes, Philological and Explanatory. By G. L. STRAUSS, Ph.D. 1s.
41-43. German Triglot Dictionary. By N. E. S. A. HAMILTON. In Three Parts. Part I. German-French-English. Part II. English-German-French. Part III. French-German-English. 3s., or cloth boards, 4s.
41-43 & 39. German Triglot Dictionary (as above), together with German Grammar (No. 39), in One Volume, cloth boards, 5s.

ITALIAN.

27. Italian Grammar, arranged in Twenty Lessons, with a Course of Exercises. By ALFRED ELWES. 1s. 6d.
28. Italian Triglot Dictionary, wherein the Genders of all the Italian and French Nouns are carefully noted down. By ALFRED ELWES Vol. 1. Italian-English-French. 2s. 6d.
30. Italian Triglot Dictionary. By A. ELWES. Vol. 2. English-French-Italian. 2s. 6d.
32. Italian Triglot Dictionary. By ALFRED ELWES. Vol. 3. French-Italian-English. 2s. 6d.
28,30, 32. Italian Triglot Dictionary (as above). In One Vol., 7s. 6d. Cloth boards.

SPANISH AND PORTUGUESE.

34. Spanish Grammar, in a Simple and Practical Form. With a Course of Exercises. By ALFRED ELWES. 1s. 6d.
35. Spanish-English and English-Spanish Dictionary. Including a large number of Technical Terms used in Mining, Engineering, &c. with the proper Accents and the Gender of every Noun. By ALFRED ELWES 4s.; cloth boards, 5s. *** Or with the GRAMMAR, cloth boards, 6s.
55. Portuguese Grammar, in a Simple and Practical Form. With a Course of Exercises. By ALFRED ELWES. 1s. 6d.
56. Portuguese-English and English-Portuguese Dictionary. Including a large number of Technical Terms used in Mining, Engineering, &c., with the proper Accents and the Gender of every Noun. By ALFRED ELWES. Third Edition, Revised, 5s.; cloth boards, 6s. *** Or with the GRAMMAR, cloth boards, 7s.

HEBREW.

46*. Hebrew Grammar. By Dr. BRESSLAU. 1s. 6d.
44. Hebrew and English Dictionary, Biblical and Rabbinical; containing the Hebrew and Chaldee Roots of the Old Testament Post-Rabbinical Writings. By Dr. BRESSLAU. 6s.
46. English and Hebrew Dictionary. By Dr. BRESSLAU. 3s.
44,46. Hebrew Dictionary (as above), in Two Vols., complete, with 46*. the GRAMMAR, cloth boards, 12s.

LATIN.

19. **Latin Grammar.** Containing the Inflections and Elementary Principles of Translation and Construction. By the Rev. THOMAS GOODWIN, M.A., Head Master of the Greenwich Proprietary School. 1s. 6d.

20. **Latin-English Dictionary.** By the Rev. THOMAS GOODWIN, M.A. 2s.

22. **English-Latin Dictionary;** together with an Appendix of French and Italian Words which have their origin from the Latin. By the Rev. THOMAS GOODWIN, M.A. 1s. 6d.

20,22. **Latin Dictionary** (as above). Complete in One Vol., 3s. 6d. cloth boards, 4s. 6d. *** Or with the GRAMMAR, cloth boards, 5s. 6d.

LATIN CLASSICS. With Explanatory Notes in English.

1. **Latin Delectus.** Containing Extracts from Classical Authors, with Genealogical Vocabularies and Explanatory Notes, by H. YOUNG. 1s. 6d.

2. **Cæsaris Commentarii de Bello Gallico.** Notes, and a Geographical Register for the Use of Schools, by H. YOUNG. 2s.

3. **Cornelius Nepos.** With Notes. By H. YOUNG. 1s.

4. **Virgilii Maronis Bucolica et Georgica.** With Notes on the Bucolics by W. RUSHTON, M.A., and on the Georgics by H. YOUNG. 1s. 6d.

5. **Virgilii Maronis Æneis.** With Notes, Critical and Explanatory, by H. YOUNG. New Edition, revised and improved With copious Additional Notes by Rev. T. H. L. LEARY, D.C.L., formerly Scholar of Brasenose College, Oxford. 3s.

5* ——— Part 1. Books i.—vi., 1s. 6d.

5** ——— Part 2. Books vii.—xii., 2s.

6. **Horace;** Odes, Epode, and Carmen Sæculare. Notes by H. YOUNG. 1s. 6d.

7. **Horace;** Satires, Epistles, and Ars Poetica. Notes by W. BROWNRIGG SMITH, M.A., F.R.G.S. 1s. 6d.

8. **Sallustii Crispi Catalina et Bellum Jugurthinum.** Notes, Critical and Explanatory, by W. M. DONNE, B.A., Trin. Coll., Cam. 1s. 6d.

9. **Terentii Andria et Heautontimorumenos.** With Notes, Critical and Explanatory, by the Rev. JAMES DAVIES, M.A. 1s. 6d.

10. **Terentii Adelphi, Hecyra, Phormio.** Edited, with Notes, Critical and Explanatory, by the Rev. JAMES DAVIES, M.A. 2s.

PREFACE.

THE object which I have proposed to myself in writing this Treatise on Logic, is the combination of a brief but complete account of the Aristotelian system, with some of Kant's philosophical views of the nature and divisions of the science. With respect to the first-mentioned part of my task, I have endeavoured to give a strictly *à priori* character to the derivation of the fundamental laws of syllogism, and the results of their combination in the various forms of reasoning. This is attempted, partly by employing a method in the derivation of these laws of a rather more exhaustive character than that which has usually been adopted by logicians,

and partly by introducing mathematical analysis, for the exhibition of the symmetry in their forms. Symbolical representation is also employed in the second section of the Introduction, for the purpose of explaining the nature of abstract conceptions, and the method of thinking some of them purely, or independently of sense.

I have derived from the *deductio ad absurdum* the grounds for a division of the twenty-four categorical syllogisms into eight systems of three each. By means of this arrangement, which to the best of my knowledge is entirely new, the equality of the number of sound moods in the first three figures, and several other properties of categorical syllogism, may be demonstrated *à priori* without the assistance of symbolical reasoning. And although these results admit of no immediate application to practice, yet are they useful in giving the student such firm hold upon the fundamental principles of the science, that they will never afterwards desert him. Besides, it should be considered a sufficient merit that they add a theoretical completeness to the science, which it can never obtain when the symmetry of

its results is arrived at by empirical methods alone.

There is another subject which has been very much neglected in all the works on Logic with which I am acquainted. Aristotle's Analytics is the only book in which I have discovered any attempt at a theory of the modality of syllogism, and on this particular point he appears to me to have failed. I have accordingly devoted an entire section to the consideration of this subject, at the end of the second book, in which I have endeavoured to expose the fallacious nature of his reasoning. It must, moreover, be remembered, that this subject is one of the most important connected with Logic, for any misconception respecting it may give birth to fallacies of a very complicated nature, and extremely difficult to detect. Perhaps not a few of the errors on the nature of the will might be ultimately traced to this source.

I will now mention as briefly as may be the extent to which I am indebted to Kant, or rather his translators, for it is by their means alone that I have had any access to his works.

The division of the science into Transcendental and Universal, (for the latter of which terms I have substituted 'Formal' as being more generally intelligible) is adopted from the Criticism, and cannot perhaps be entirely comprehended without a reference to that work. The first part of the second section in the Introduction, and a great part of the third, are little more than an abridged paraphrase of some portion of his Logic. There are also several other places throughout the Introduction which have at least originated in some idea derived from his works, though it is impossible individually to specify them here.

In the first book, which contains the merely formal analysis, I have adopted the opinion of Kant respecting the distinct nature of Categorical, Hypothetical, and Disjunctive propositions. But as the latter part of the first book is entirely opposed to his opinion on the philosophical correctness of the distinction of figures, it will be necessary to account for my having thought proper to retain the scholastic theory on that subject. Many other reasons might probably be urged

in favour of this view, but one alone is amply convincing to myself. The *deductio ad absurdum* can only be applied to some syllogisms in the first figure, by the introduction of those moods of other figures which cannot be reduced to the first by conversion; and the indirect proof of these syllogisms would only restore the original syllogisms in the first figure. There are one or two other points in which I have not followed Kant, and which are immediately consequent upon the adoption of the system of figures. These it is not necessary to specify here; for if the reader is acquainted with the works of that philosopher, he will readily detect them for himself; and if he is not, he would not understand my explanation.

Material fallacies, ambiguous terms, and many other similar subjects which are usually considered in works on this science, have found no place in the following pages. All these subjects have been already discussed by Dr. Whately in such a very able and lucid manner, that nothing more remains to be said about them. And even had this not been the case, my silence respecting them could not have

been considered an omission, as they never entered into the plan of my work.

I have attempted little more than an analysis of the formal laws of reasoning, and how far this attempt has been attended with success, the reader can now determine for himself.

Cambridge, May 13, 1839.

TABLE OF CONTENTS.

INTRODUCTION.

SECTION I.—NATURE AND DIVISIONS OF THE SCIENCE.

Art.

Legality of the Understanding 1
Legality of the Reason 2
A priori Character of their Laws 3
Division of Logic into Transcendental and Universal or Formal 4
Proper Province of Logic 5
Logic not an Organum 6
Notice on Whately's Logic ... ... 7—9

SECTION II.—COGNITION.

Definition of Cognition 10
Distinct and Indistinct Cognition 11
Conceptions, how obtained 12
Their Matter and Sphere... 13
Their Rank 14
Symbolical expression of the Nature of Abstract Conceptions ... ... 15—17
Of certain pure Conceptions ... 18—20

SECTION III.—JUDGMENTS.

Art.

Judgments distinguished as to their 21
Quantity, into Universal, Particular, Singular 22
Quality, into Affirmative, Negative, Indefinite ... 23
Relation, into Categorical, Hypothetical, Disjunctive 24
Modality, into Problematical, Assertive, Necessary 25
Propositions 26
Synthetical and Analytical Judgments ... 27
How confounded 28
Definition 29
Several applicable to the same thing 30

BOOK I.

SECTION I.—CATEGORICAL PROPOSITIONS.

Their Form 31
Their Number 32
Law for Quantity of Predicates 33

SECTION II. — MUTUAL RELATION OF CATEGORICAL PROPOSITIONS.

Opposition of three kinds—Contradictory, Contrary, Sub-contrary .. .. 34—36
Subalternation 37
Conversion 38

SECTION III.—HYPOTHETICAL AND DISJUNCTIVE PROPOSITIONS.

Form of Hypothetical Propositions 39
Admits no Variations 40
Their Contradictory Categorical 41
Their Nature distinct from that of Categorical Propositions 42
Disjunctive Propositions 43
Have no Contradictory 44

SECTION IV.—SYLLOGISM. Art.

Syllogism defined 45
Its Divisions 46
Categorical Syllogism 47
Method to be adopted in determining its Laws .. 48
Its Elements 49
Division of the Enquiry 50
Law for the Middle Term 51
Quality of the Premises 52
Forms of Premises from which a Conclusion for the Reason is possible 53
Conclusions inexpressible in the legitimate Categorical forms 54
Illicit Processes 55
Quality of Conclusion... 56
Recapitulation of the Laws of Categorical Syllogism 57
Secondary Laws 58
Table of Sound Moods 59
Division into Figures and complete Table of Categorical Syllogism 60
Laws peculiar to different Figures ... 61
Transformation of Figures and Table 62
Rejection of certain forms of Syllogism considered. Table of Moods for each Figure 63
Hypothetical Syllogism 64
Disjunctive Syllogism 65
Dilemma 66
Other forms of Syllogism 67
Enthymeme 68
Sorites 69

SECTION V.—THE DEDUCTIO AD ABSURDUM, ITS NATURE 70
Affords the grounds for a Symmetrical Division of the 24 Syllogisms into eight Systems ... 71

SECTION VI. — SYMBOLICAL EXPRESSION FOR THE SYLLOGISTIC LAWS.

Art.

Fundamental Equations 72
Symmetry of the Equations to the first three Figures 73
Number of possible Solutions 74
Derivation of Secondary Laws 75
Truth of Premises 76

BOOK II.

SECTION I.—LIMITATIONS OF THE FORM OF JUDGMENTS.

Conception of Substance never a Predicate ... 77
Law between Predicate and Copula 78
No formal proposition of Identity 79
Relative merits of the four Figures 80
True Conclusions from false Premises ... 81
Conclusions of the Reason 82

SECTION II.—MODALITY OF SYLLOGISM.

Does not affect the form of Conclusion ... 83
Proper and Consequential Modality distinguished 84
Proper and Derived Modality distinguished ... 85
No conclusion from Problematical Premises ... 86
The law of Derived Modality 87
Fallacies in Aristotle's Analytics arising from the breach of this law ... ... 88—90

APPENDIX.

Examples for practice 155
Mathematical Note 160
Index to the principal Technical Terms ... 161

A

SYLLABUS OF LOGIC.

INTRODUCTION.

SECTION I.

ON THE NATURE AND DIVISIONS OF THE SCIENCE.

(1.) The subjection of the Understanding to certain invariable laws is the first indispensable condition to all knowledge. Kant has shewn, in his Criticism on the pure Reason, that the mind legislates for matter, or in other words, that the laws we discover in the external world derive their very possibility from the laws of Mind. But let us for an instant imagine the possibility of nature following fixed laws as an object of our senses, quite independently of any laws in our understanding, which for argument's sake we will suppose to be without them. It is evident that upon this hypothesis the Understanding could never take cognizance of these

laws of nature, nor even of the existence of the objects they concerned. For these objects can only become known to us by means of certain laws, according to which we can severally distinguish them from each other: and how could we even distinguish between ourselves and nature, or between the 'me' and the 'not me,' without some law in the faculty by which objects are known?—Every change in our representations might either arise from a change in nature, or from a change in our own indeterminate state. But even could we separate ourselves from nature, there would still remain the question, 'How can we conjoin any phenomena in a synthesis for the purposes of knowledge, unless we are conscious of something fixed and determinate to which we can refer all the phenomena to be conjoined, and also of some law for the mode of their conjunction?' Without these requisites the cessation of the phenomena and of their conjunction in the mind must be simultaneous. And, moreover, even while the phenomena lasted, no act of conjoining them in any one instant of time could ever be considered the same as, or be united with a similar act of conjoining them in any succcessive instant, unless we were to grant something fixed in our consciousness, and

quite independent of time, as a common ground for the unity of these successive syntheses. Hence, upon every hypothesis, the legality of the knowing faculty is a necessary condition to its use; and it now only remains to extend this remark to the other logical faculty —the Constructive Reason.

(2.) The Understanding has been defined by Kant, as 'the faculty of rules;' by Coleridge, as 'the faculty of judging according to sense.' Its operation may be considered as two-fold, accordingly as it dissects a representation by analysis, or conjoins several representations in a synthesis. But there can be no act of analysis without the consciousness of a prior synthesis; and hence it follows, that the latter is an indispensable condition to every act of the faculty. Now the Reason, considered as to its logical use, (its transcendental use has nothing to do with our present purpose, and need not be considered here,) differs from the Understanding in this: Whereas the Understanding merely conjoins the diversity of representations in synthesis, or dissects them by analysis, in either case referring this diversity to the unity of consciousness; the Constructive Reason on the other hand conjoins the very unities of these syntheses, which unities are acts in the consciousness

or logical functions of the Understanding, and entirely distinct from the diverse representations contained in them.* But as this kind of reasoning is rather difficult to comprehend in the abstract, we shall endeavour to explain our meaning by an example:—If any person were to state the two propositions, 'all tyrants are unhappy,' and 'Nero was a tyrant,' my Understanding alone could never have enabled me to discover that 'Nero was unhappy.' For this faculty unaided by the Reason could only conjoin certain conceptions according to a rule. For instance, I

* If we might be permitted to offer an illustration of so abstract a subject, we would represent the synthesis of representations in the Understanding by the arc of a circle connecting two points, whose centre or unity of the syntheses may be of course at a finite distance. But if another point be taken in the same right line with the first two, we can only join all these points, and make the centres of the two arcs correspond, by placing the common centre at an infinite distance, where it will represent the Reason conjoining the unities of the syntheses of the Understanding. It must also be observed, that as on the one hand the centre of this circle is infinitely distant, but its arc, which is a straight line joining the three points, is finite and determinate; so on the other hand the rational act of conjoining the unities of the syntheses of the Understanding transcends all possible experience, and cannot be represented, but can only be thought, whereas the synthesis, which results from the act of reason, is quite as easily represented as those from which it was originally derived. We are perfectly aware of the manifold objections which might be urged against this illustration, but we are inclined to think it may, in some measure, assist the reader in comprehending the idea we wish to convey.

may severally conjoin the conceptions of unhappiness and Nero with the conception of tyrant, as in each case belonging to the same subject: but in order to conjoin the two extreme parts of these judgments, namely, Nero and unhappiness, I must simultaneously reflect on my previous conjunction of each of them with the conception of tyrants, and therefore on the two acts of the Understanding by which these judgments take place. Before then I can arrive at any conclusion from the two given propositions, I must possess some faculty by which I can conjoin the very acts of the Understanding that are contained in them, and this is what is meant by the Constructive Reason.

The ease with which the Reason arrives at a conclusion from judgments that have been reduced to their most simple logical form, and the perfect similarity of such a conclusion when obtained to any immediate act of the Understanding, are circumstances which have rendered the peculiar function of the Reason, in its logical use, extremely liable to be overlooked. But a little attention to the subject will make it evident, that the conjunction of the acts of the Understanding requires quite another faculty than that of the Understanding itself, which merely conjoins

the parts of possible experience according to rules.*

Having given this short account of the logical use of the Reason, we shall now proceed to shew that its functions are entirely determined by laws. For as the conclusions of the Reason are constructed with materials derived from the use of the Understanding, they can only concern the objects of the latter faculty, and must in their intrinsic nature be possible as its immediate acts. But this harmony of the two faculties can only be secured by the subjection of the Reason to laws. Here then at length we are justified in assuming, that the whole use of our intellectual and rational faculties is based upon certain universal laws, and that the Science which treats of them is not a mere chimera of the imagination, but founded on a reality which is the primary condition to all other knowledge whatever.

* After the author had written his account of the logical use of the Reason, he met with the following passage from Kant. It refers, however, to the whole use of the faculty:—

"The Understanding may be a faculty of the unity of phenomena by means of rules; Reason is thus the faculty of the unity of the rules of the Understanding under principles. Reason, therefore, never refers directly to experience, or to an object, but to the Understanding, in order to give to the diverse cognitions of this, unity *à priori* by means of conceptions, which may be termed unity of Reason, and which is of quite another kind to that which can be derived from the Understanding."—*Anonymous Translation of Kant's Criticism.*

(3.) The laws of the use of the Understanding must be *à priori*, and cannot be derived by the method of induction from any number of mental phenomena. For it has been shewn that they are necessary to all use of the Understanding, (as it cannot even determine an object without them,) and consequently to experience itself; and we should therefore be guilty of a glaring circle in our reasoning, if we endeavoured to derive from experience those laws which have previously been made the very grounds of its possibility.*

But if the laws of the Understanding are

* The commonest example of this most fallacious attempt to deduce the pure conceptions of the Understanding from experience, is to be found in the grounds that are sometimes given for the causal relation of phenomena. For instance: *Q.* Why do I expect a spark from the concussion of flint and steel? *A.* Because in all past time such a concussion has been immediately succeeded by a spark.—*Q.* But why does this succession having taken place in all past time, give me any right to expect that it will take place again? *A.* Because any succession that has taken place very often, has been afterwards observed to take place again. And if we were to ask for a reason, why the uniformity of nature up to the present moment should be considered as any guide for the future, we should get precisely the same answer, or in other words, the fact would be stated as the ground for itself. And we might thus continue the question and answer to infinity, without ever getting any nearer the point. The difficulties of this subject were first brought to light by the subtilty of Hume. And although he never succeeded in offering any satisfactory solution of them, yet his "sceptical doubts" aroused the attention of Kant, and became the occasion of the Criticism on Pure Reason, in which the difficulty is satisfactorily explained.

independent of all empirical matter, *à fortiori* must this be the case with the formal laws of the Reason, which simply regard the conjunction of the acts of the former faculty, and are therefore removed one step farther from their empirical contents. Hence it follows that both Reason and Understanding are entirely self-regulated, or subject to *à priori* laws. And the determination of these methodically, and their arrangement in a system, is the business of Logic in the widest acceptation of the word.

Division of Logic.

(4.) Logic is divided by Kant into Transcendental, and Universal or Formal.*

Transcendental Logic agrees with Formal in excluding all consideration of particular objects, but differs from it in admitting that of the pure conception of an object in general.

Formal Logic entirely excludes all consideration of the objects thought, and merely re-

* The reader who has no acquaintance with the Kantian system, must not be surprised if he does not clearly understand the distinction between these branches of the science. As, however, Formal Logic is exclusively the subject of the first book, and a few considerations from Transcendental are introduced in the second—the two books together may throw some light upon the nature of the division in question.

gards the form of our judgments, and their relations to each other.

It will be seen from the above definitions that Transcendental Logic embraces a very wide field, and includes within its limits much that is metaphysical, and entirely foreign to the other branch of the science.*

As Formal Logic alone is the proposed subject of this treatise, we should have been justified in taking leave of Transcendental Logic here: but certain limitations are imposed upon the very forms of the judgments of the Understanding by conceptions which are peculiar to the last-mentioned science. And although they may be justly assumed in every treatise on Formal Logic, yet, as they are the origin of several very peculiar results,† we thought the notice of them in our second book might be deemed not wholly superfluous.

(5.) This apology has been offered for an intended reference to what properly lies out of the sphere of the subject, on account of the great injury which the sciences must in-

* For instance, the conceptions of substance, causality, &c.

† Some of the limitations are alluded to in the commencement of the first book. The absence of a formal proposition of identity is one of them. For if we say A is B, we do not know but that other things may be B also. One of the peculiar results is the "possibility of a true conclusion from false premises in every form of reasoning."

variably incur whenever their boundaries are not strictly recognised. Formal Logic has, perhaps, suffered more on this score than any other science: for, to say nothing of many encroachments on the side of Transcendental Logic, it has been a common custom with logicians to introduce into their treatises a great deal of matter derived entirely from empirical psychology, which is a distinct branch of knowledge. Thus, the choice and arrangement of arguments, the best application of particular syllogistic forms, and other similar considerations, have frequently been made the subject of rules which can only be derived from practice, and should never be mixed up with Logic, which is an *à priori* science. Observations of this kind can never form part of a system, but are merely an aggregate of information, which is very useful no doubt, but belongs more particularly to the Art of Rhetoric. Knowledge of this kind may properly be termed an art, and so far the old logicians were at least consistent. But this term can never be applied to Logic without an absurdity as manifest as if we were to speak of the Art of the Differential Calculus, or Conic Sections.*

* We have thought it better to put a few observations on Dr. Whately's Definitions of Logic in a notice by themselves at the end of this section.

(6.) Logic is not an organum of the sciences; for it does not contain a single reference to any one branch of knowledge, and therefore has no resting-place or fulcrum from which to commence its investigations: it is however of the greatest use in testing the work of another organum, by exposing all its results. When a new law has been arrived at by Induction, Logic will determine all its consequences; and should one of these prove at variance with truth, it is certain that the induction is erroneous, and that new observations are necessary.

Notice on Whately's Logic.

(7.) As the distinction between the theory of Logic and its application to practice has been well explained in the very valuable treatise by the Archbishop of Dublin, we cannot help feeling in some measure surprised that he has united these very different subjects in the same definition. In the introduction to his work, Dr. Whately defines Logic as the "Science, and also the Art of Reasoning;" and afterwards explains in a note, "that as a science is conversant about knowledge only, an art is the application of knowledge to practice." Now it follows from the latter unobjectionable definition, that the rules for the art must be merely practical, and derived

from the experience of "how we reason best," or in other words from empirical psychology; for if they were *à priori*, they would *ipso facto* become laws of the science. Hence we see that the rules of the art, which are all empirical and depend on observation, differ from the laws of the science, which are *à priori* and derived from the reason, not only in their use and nature, but also in their origin. The question however is not one of fact, or even of theory, as Dr. Whately has himself introduced the very distinction for which we are contending: but the question *is*, whether that arrangement can be considered conducive to the interests of science, which combines under the same name two branches of knowledge whose nature and origin are equally distinct from each other.

(8.) There are two other passages in Dr. Whately's work, which appear to the author to contradict each other, and to convey equally false notions of the nature of the science. Soon after the definition upon which we have just commented, Dr. Whately adds, "Its most appropriate office however is, that of instituting an analysis of the process of the mind in reasoning." Now it is not the process of the mind in reasoning, but the principles with which that process must accord, that is the proper object of

Logic.* We hardly ever reason to ourselves in syllogism, but only in a manner which agrees with its laws. For instance, if I think of the future death of a hale and hearty man, in whom there do not appear the slightest symptoms of decay, I do not consider it a merely probable circumstance, but morally certain. Now this conclusion could only be logically deduced by my virtually assuming the proposition that 'All men must die,' and therefore that John being a man must die also. But although the actual law which connects humanity and mortality must have been thought in my mind, when I first considered it as morally certain that John must die, yet the proposition that 'all men must die' (which is, as it were, the exponent of the law) had, in all probability, never occurred to me: perhaps, indeed, so far from thinking of all mankind, I had not thought of any other person than John. We see then that the object of Logic is not the actual process of our reasoning, but rather the principles to which that process can always be referred.† And it must be remembered that

* Dr. Whately admits that Logic "investigates the principles on which augmentation is conducted;" and had his definition terminated here, it would not have been liable to any objections.

† The simple state of the case is this: In the actual process of our minds we generally connect the mere conceptions in a law, without thinking of all that is contained in their sphere. But

this is no unimportant point in the definition of Logic, as an erroneous conception on this head is extremely calculated to bring the science into disrepute. For, if any one discovers that the process of reasoning in his own mind is rarely, if ever, in the form of a complete syllogism, he immediately leaves the science with the conviction that it certainly does not contain the principles of all reasoning, and probably not of any.

(8.) The other passage to which we would allude, is to be found in a note near the commencement of the second book, in which Dr. Whately states, that "Logic is entirely conversant about language."

This appears to us to be at variance with the passage we have just quoted, in which the most appropriate office of Logic is said to be the analysis of the process of the mind in reasoning. Now, that language follows certain laws, is unquestionably true. But whence do these laws arise, unless from the necessity

in the logical development we consider the aggregate of individuals that come under the conception contained in the subject of an universal proposition. As, for instance, in the above example, if I look at John and think of his future death, I merely connect the conception of death with that of humanity, to the conditions of which I see that he corresponds. But if I am asked to express logically my reasons for expecting his death, I immediately commence with 'All men die,' &c.

of language conforming itself to the mental laws of which it is the exponent? If language did not receive its stamp from mind (the laws of which we assume to be universally the same in all countries and ages), we could never be certain that we might not at some future time meet with a people whose language required quite a new logic, and in that case the science would lose its *à priori* character, and rest on probability alone.

SECTION II.

ON COGNITION.

(10.) COGNITION is the generic name for all representations that are sufficiently completed for the logical use, and must therefore contain a reference to our consciousness on the one hand, and to an object on the other.

If a cognition contain sensation, it is empirical; if it does not, it is pure.

Cognition may be divided into the two species—Intuition and Conception, each of which may be either pure or empirical.

Intuition is a merely sensual* cognition of an object.

Conception is an intellectual cognition, and refers to many objects.

Perhaps we can exhibit these co-divisions of cognition in a more intelligible manner by means of the following scheme:—

COGNITION TABLE.

	INTUITION.	CONCEPTION.
Pure.....	A straight line.	Substance.
Empirical..	A horse that is seen.	Abstract conception of a horse.

* Pure Intuitions concern the mere forms of the Sensitivity, Space, and Time, and are therefore sensual without containing sensation.

To investigate the ultimate original of cognition, and shew by what process a merely sensual representation obtains objective validity,* and thus becomes an intuition, is entirely foreign to our present purpose, as it belongs to the science of Metaphysics. We shall therefore only explain that formal property of our cognition upon which its logical perfection mainly depends, and conclude the section with investigating those logical acts of the understanding by which it arrives at conceptions.

(11.) Cognition may be divided into distinct and indistinct.

Indistinct cognition is that in which a diversity is thought, that is not exhibited objectively to the consciousness.

Distinct cognition, on the contrary, is that in which no diversity is thought, which is not exhibited objectively to the consciousness.

Let us take an example of an indistinct intuition.

While walking on the sea-shore, I perceive a large object in the offing, which, from its general appearance, I immediately know to be a ship. Now, from my previous knowledge of

* We give objective validity to a representation, when we conceive it to arise from something independent of the peculiar state or nature of our own mind, and therefore believe that other people would view it as we do.

the construction of a ship, I know that it must have a rudder, shrouds, and a great variety of tackle, which are not to be found in the image as it appears to me, although I must really see them: I therefore say that my intuition of the ship is indistinct. If, on the other hand, I had never seen a ship before, and had no conception of the nature of the object presented to me, I should say that my intuition of the object was distinct; and this would arise from my ignorance of what there was in it to distinguish. But if any person then asked me 'if I could see what the object was?' the question 'what?' would superadd in my mind a conception of this object, having some nature peculiar to itself, or having been made for some particular purpose, which was not exhibited to me in my intuition, and I should therefore answer that I could not see distinctly what it was.

Hence we see that an intuition is indistinct, when it suggests a conception of the diverse, which it does not exhibit objectively to the consciousness. And it is the relation of our conception to the representation, and not the latter alone, upon which distinctness must depend. For if distinctness were defined as the consciousness of the diversity of the representation, without introducing any limitation

to this diversity, distinctness would be impossible, as the diversity in any object is infinite, and can never be exhausted.*

In the same manner we say that a conception is indistinct, when we attach to it the conception that an analysis of it is possible, or in other words that it contains a diversity, and yet cannot dissect, and severally represent to our consciousness† the parts of this diversity. For instance, we may be said to have an indistinct conception of the nature of the human mind, when we attach to it the conception that some analysis of its different powers is possible, and yet cannot exhibit these powers separately to our consciousness.

Conceptions.

(12.) The logical acts by which the understanding arrives at conceptions are three, —Comparison, Reflection, and Abstraction.

Comparison is that act of the understanding by which several representations are referred to the consciousness simultaneously.

* It is evident from this that distinctness is relative, not positive. And we have dwelt the more upon this, as it does not seem to be very clearly laid down in Kant's Logic.

† If the remarks in the text are founded on truth, it will follow that an increase of knowledge may sometimes render a previously distinct conception indistinct, by destroying the equality between that which we know to be in it, and that of which we are conscious.

Reflection is that act of the understanding by which we determine what is common to several representations, and consequently how we may embrace them in one conception.

Abstraction is that act of the understanding by which we separate all that is not common to several representations.

For example, if I compare several men, I reflect on their resemblance as bipeds that walk erect, and abstract their differences as to height, complexion, &c., and thus arrive at a conception that answers to all of them.

Matter and Sphere of Conceptions.

Conceptions may be considered either as to their matter, or as to their sphere.

(13.) The matter of a conception consists of the various representations contained in it.

The sphere of a conception consists of the things that come under it, or answer its conditions.

As any addition to the matter of a conception is a new condition to be answered, and as a part of the original sphere of the conception probably does not answer this new condition; it follows that the conception thus altered by an addition to its matter will have a less sphere than that of the original conception. Hence it is evident that the sphere and

matter of a conception vary inversely, and that the more matter there is in a conception, the less is its sphere. Let us take an example. The conception of a horse has more matter than the conception of an animal: for the former conception must contain all that is contained in the latter conception, and something more besides. But the sphere of the conception of a horse is less than the sphere of the conception of an animal; as there are many more things that answer the conditions of the latter than the conditions of the former conception.

Rank of Conceptions.

(14.) Superior and inferior conceptions are merely relative terms. The inferior conception contains all the matter of the superior conception, and something more besides, but is itself contained under the superior conception. For example, the conception 'horse' is inferior to that of 'animal.'

A superior conception is also termed a genus, and an inferior conception a species. There can be a highest genus, but there cannot be a lowest species; for we may continue to abstract matter from a conception till we have left so little in it, that the next step would take the conception away entirely. This con-

ception must then be the highest, for it is impossible to think of another superior to it, under which it might rank. But we can never arrive at a lowest species; for though we continue to increase the matter of the conception, and thereby lessen its sphere, we can never be certain that we have exhausted all the possible partial representations, which may make distinct species under this conception, and thus render it a genus: for instance, I may gradually abstract from my conception of 'horse' through the steps of 'quadruped,' 'animal,' and 'organic being,' till at last I arrive at mere being, from which I cannot abstract any thing more. This conception must therefore be considered as a highest genus. But if I take the conception of 'horse,' and continue gradually to increase its contents, I can never be certain that there may not be other unknown distinctions in horses, which might constitute the grounds of a division into still lower species.

But although we can never arrive at a lowest species (which must of course be a conception), we can very easily complete the determination of a cognition by fixing its individuality in Time and Space.

Symbolical expression of the nature of Abstract Conceptions.

(15.) A conception may be symbolically represented as the common measure of the representations from which it is derived. For if we express the various parts of a representation by the letters *a, b, c,* &c., and the whole representation as their product,* we may consider the following quantities as the expressions for three different representations,

$$a\,b\,c\,d\,e\,f,\quad b\,c\,d\,f,\quad a\,b\,c\,d\,e,$$

where it is evident that the conception obtained in the manner already explained, will be symbolically represented by the common measure *b c d.*

It frequently happens that we cannot image to our minds the conceptions we obtain by reflection and abstraction; for sometimes the representations from which we wish to obtain a conception, have not a single sensible partial representation in common, but only a law connecting their parts. And although this law may always be thought, yet it cannot be imaged to the mind, as the image could only

* In the following symbolical exposition of the nature of abstract conceptions, we have thought it better to retain the names for the operations that are suggested by arithmetical algebra. The terms, 'product,' 'multiplication,' &c. must therefore be understood as merely referring to the corresponding symbolical operations.

represent a particular case. If, for instance, I witness a great many cases of the rebound of elastic bodies from a smooth surface, perhaps the only thing these cases have in common is the equality of the angles of incidence and reflection, which cannot be imaged to the mind, but can only be thought. For an image could only give us the representation of the equality of two particular angles, but the conception of the equality generally could only be thought in the understanding. This may be symbolically expressed as follows.

Let the representations be

$$b \,.\, \phi(b), \quad e \,.\, \phi(e), \quad h \,.\, \phi(h).$$

Now, in arithmetical algebra these quantities would have no common measure, but in symbolical algebra we may separate the symbol of affection ϕ, and consider that as the symbolical representation of the conception of the law. And it must be observed, that as a general law may be thought and employed in reasoning, but cannot be imaged (which is only possible for a particular case), in like manner the function ϕ, which is a symbol of affection, may be employed in analysis as a medium of reasoning, but can never be itself interpreted in all its generality in any subordinate science, as its interpretation is only possible by its union with some particular symbol of quantity.

(16.) It is impossible to obtain a correct abstract conception of the organic productions of nature. For let us take as an example the conception of man. If we were to proceed in accordance with the simple method already proposed, and abstract every thing that is not common to all men, we should obtain a conception in which no one could ever recognise the least semblance of humanity: it must possess neither arms, legs, eyes, ears, nose, teeth, hair, or the power of speech,—for men exist who are separately deprived of each of these things. Our abstract conception of the human form divine would therefore contain a trunk without a single limb, and a scull without a single feature.

Again, if we determine in our own minds the greater part of a horse (all but the tail for instance), in conformity with our general conception of that animal, we may allow variations in that one part between very wide limits, and yet consider the whole result as coming under our conception of a horse. In the same manner we might allow any other part of the horse to vary between very wide limits, provided the rest resembled the corresponding parts of horses generally, or of any well made horse in particular: but were we to introduce all these

variations simultaneously, the result would be a monster, to which our conception of 'horse' would be no longer applicable. Hence we see that the several parts of our conception must be considered as functions of other parts, and all mutually dependent on one another. And retaining the symbolical language we have already employed, where u, v, w, &c. express the partial variable representations, we might write

$$\text{abstract conception} = \mathrm{F}(u, v, w, x, y, z)$$

$$\text{where } \phi(u, v, w, x, y, z) = 0;$$

and every set of values that answers the conditions of the equation will correspond to an individual of the species.

(17.) A friend once suggested to the author that there was a great analogy between an abstract conception and an enveloping curve; and after a little consideration he discovered that the symbolical expression for the envelope is not a mere illustration, but a strictly correct representation of the nature of an abstract conception.

Instead of representing each individual of a species by a function of a particular set of values for u, v, w, &c., let us consider the whole locus*

* As the original (*i.e.* geometrical) signification of the word 'locus' is necessarily confined to functions containing not more than three variables, it may be as well to remark, that we have adopted it here in the strictly analogous sense of 'interpretation of an equation.'

of an equation as but one individual. If then this equation contains a constant (a)* to which we give continuously successive values, we shall obtain a family of these equations to individuals whose loci will intersect each other (in a locus of one dimension less than themselves), and the envelope or locus of these intersections will be a correct symbolical representation of the conception abstracted from them all. For we may consider an abstract conception as one which contains all the points of resemblance between any individual, and those immediately preceding and succeeding it.

We therefore discover a perfect analogy between abstract conceptions and enveloping surfaces or curves: and the only difference in their respective symbolical representations consists in the number of variables which we are justified in introducing in either case. For the equations whose interpretations relate to space cannot of course have more variables

* It may be as well to remind the reader, that though the constant (a) is a symbol of quantity in the function considered simply symbolically, yet it becomes a symbol of affection (in fact a part of the function) in the interpretation: the symbol (a) is therefore to be considered as a part of the law between the members of the individual; just in the same manner as a constant in the equation to a surface or curve is only interpreted through its affecting the variables.

than space has dimensions, and are therefore confined to three: whereas the variables introduced in our abstract conceptions concern many other things besides space, and are therefore unlimited in number. We subjoin the symbolical expression for the enveloping or abstract conception.

Let $F(u, v, w, x, y, z, a)$ represent the locus of an individual: then the locus of the enveloping conception will be expressed by the equations

$$F(u, v, w, x, y, z, a) = 0 \quad . \quad . \quad . \quad (1)$$

$$\frac{dF(u, v, w, x, y, z, a)}{da} = 0 \quad . \quad . \quad . \quad (2).$$

And if a is eliminated from (1) and (2) we shall have an equation of the form

$$\phi(u, v, w, x, y, z) = 0,$$

which represents the locus of the abstract conception.

(18.) Before we conclude this section, it may be as well to add a few remarks on the method of thinking certain conceptions purely or independently of sense.

The idea of a limit, which is the basis of the differential calculus, supplies the only possible means of thinking the conceptions Substance and Causality purely, *i. e.* independently of all empirical matter. For in order to think the

conception of Substance at all, I must imagine certain phenomena, and then conceive the objective existence of a substratum for their support. But this alone is insufficient, for although the conception of Substance is obtained, yet it is not pure as long as it contains any sensation or phenomenon. I must, therefore, diminish my sensation till it approximate to zero. This, however, must not be effected by lessening its extension in space, for in that case the object itself would vanish, as its identity and objective existence can only be determined in that form of sensation. Neither, on the other hand, may the sensation be diminished as to its intensity: for although this operation would only affect the conception of its being an object for me, and not of its being an object at all, yet this mode of diminution would introduce the conception of successive states, and therefore other matter besides the bare conception of Substance.

The only way that remains is that of diminishing the time in which the phenomenon is viewed, till we arrive at the limit. If then we consider time as the independent variable, and the phenomenon as a function of it, the pure conception of Substance will be properly represented as the limiting ratio between the phenomenon and the time in which it is viewed.

Let S = the pure conception of Substance, P = phenomenon, and T = time in which the phenomenon is viewed, we shall then have

$$S = \frac{dP}{dT}.$$

And as the conception of Substance contains permanence, it follows that S is constant. We may therefore consider

$$P = S\,T.$$

as the equation to a phenomenon to which the pure conception of Substance alone is applicable.

(19.) Very nearly the same reasoning will apply to the conception of Causality. This can only be imaged to the mind in a succession of phenomena occupying finite portions of time. But while our conception contains sensible phenomena, it is not pure: we therefore diminish the conceived duration of the times in which they exist, till they approximate to zero. When they arrive at this limit the conception becomes pure, for the phenomena will only occupy successive instants of time; and must therefore vanish. Hence we see that the two cases resemble each other, inasmuch as they are each represented by the limiting ratio of the phenomenon to the variable time. They differ however in this: whereas the phenomenon from which the conception

of Substance alone was derived did not vary in time, but bore a constant relation to it; in the latter case the phenomenon will vary, and consequently be some unknown function of time. If then the pure conception of Causality = C, and the other symbols retain their former signification, we shall have

$$P = \phi(T, S),$$

$$\text{and } C = \frac{d\phi(T, S)}{dT}.$$

(20.) If the reader will examine his conception of $\frac{dy}{dx}$ and also of one of these categories, the analogy between them will become immediately evident. The ratio $\frac{dy}{dx}$ cannot be imaged to our minds (because we cannot image the ratio between two nothings), but it can be thought. For we can very well understand that there may be such a relation between two quantities, as that the nearer they approximate to zero, the nearer does their ratio approximate to equality with some given ratio, and that the two approximations are completed simultaneously. Exactly in the same manner the pure conception of Substance cannot be imaged;* for we cannot image that,

* "The invisible was assumed as the supporter of the apparent, *τῶν φαινομένων*—as their substance, a term which in any other interpretation expresses only the striving of the imaginative power under conditions that involve the necessity of its frustration."—*Coleridge's Friend.*

which, considered as to space and time, and the sensation contained in them, is equal to zero. But it may be thought: for we can very well understand that there should be in our minds a law or *à priori* relation between phenomena and the time in which they are viewed, and that this law should retain its signification even when the phenomena and their time both = 0. It is, however, quite beyond the powers of symbolical representation to give the nature of these conceptions themselves. Nothing more is here intended, than to express, by an analogy to the mathematical idea of a limit, the only method by which these conceptions can be thought pure, and independent of the possible experience to which they are necessary.

SECTION III.

JUDGMENTS.

(21.) A judgment is that act of the understanding by which it determines how certain representations may be conjoined in the consciousness according to some rule of its own.

Kant has divided the consideration of judgments as to their form into the four points of Quantity, Quality, Relation, and Modality; and each of these again into three subdivisions or moments,* from which he derives the twelve categories, or pure conceptions of the understanding.

Quantity.

(22.) The three moments of Quantity are the Universal, the Particular, and the Singular. These determine the quantity of the subject of a judgment, and refer respectively to the whole sphere of a conception, to a part of the sphere

* Our choice of the word 'moment,' was entirely determined by its having been employed in this signification by the anonymous Translator of the Criticism.

of a conception, or to an individual; *e. g.* All men are mortal; some men are mortal; John is mortal.

In Transcendental Logic we distinguish between the Universal and Singular, because the subject of the former is in respect of its formal quantity unlimited, whereas the subject of the latter is completely determined. If, for instance, I speak of 'all men,' there is nothing in my bare conception of man which can put any limit to the number of individuals that may come under it, or answer its conditions; and the quantum of the sphere of the conception is therefore formally indeterminate: whereas, if I speak of an individual, John, my cognition contains all that is found in the conception of man, and also the possibility of his complete determination in space and time, for on that his identity depends.* But For-

* That our conception of identity requires us to think the possibility of determining the object in a particular space at a particular time, is evident from the consideration that there is no limit to the number of individuals who may exactly resemble each other in all other respects. Now the particularity of space and time is determined by a reference to ourselves; for we can only think of a particular time as being at such a period before or after the present time, or that in which we are thinking, and of a particular space as being at a certain distance from the present space, or that in which we are now sensible: hence, the identity of all external objects ultimately depends on a reference to the identity of the thinking subject. But if I endeavour to represent my own identity, I must have recourse to the identity of external objects;

mal Logic takes no cognizance of the object thought, and consequently does not recognise the distinction: for in speaking of an individual man, I speak of all that answers to my cognition, and that is all that Formal Logic can require for an Universal. This science therefore acknowledges only the two moments, Universal and Particular.

Quality.

(23.) The three moments of Quality are—the Affirmative, the Negative, and the Indefinite.

The first, as its name implies, affirms the predicate of the subject; the second denies it; but the third affects the matter of a conception which it limits by entirely excluding it from some particular conception. Thus, 'not A' is indefinite, as it applies to any thing that lies out of the sphere of A. As every thing

e. g. I may represent myself to myself as the person who was in a particular room at a certain time: hence it follows, that I think of the identity of other objects by means of a reference to myself, and of myself by means of a reference to other objects. There is, then, between the 'me' and the 'not me' a kind of polarity, which existing in space and time according to some undiscoverable law of the consciousness, gives rise to the conception of identity. This may be illustrated by representing space and time as the axes of co-ordinates, and our own mind as the origin from whence any values of x and y may be measured for the determination of an object. Or if we think of our own identity by means of that of another object, we must place the origin at the object, and consider our own mind as the point to be determined.

must be either A or 'not A,' it is the same thing whether 'not A' be affirmed or A be denied of any subject; and for this reason the Indefinite is not considered in Formal Logic, as the Negative moment can always take its place.

Relation.

(24.) The three moments of Relation are—the Categorical, the Hypothetical, and the Disjunctive.

The first of these considers the relation of cognitions to the same substratum or substance. The second considers the dependence of one cognition as consequent upon another as antecedent. The third considers a reciprocity of relation between cognitions in such a manner that any one of them can be known by the determination of all the rest. The most general form of a Categorical judgment would be 'A is B,' or 'No A is B,' in which the conception B is asserted to belong, or not to belong, to the subject A. An Hypothetical is of the form 'If A is B, C is D,' in which the judgment that 'C is D' is made to depend as consequence upon the judgment that 'A is B' as antecedent. Either 'A is B, or 'C is D,' is a Disjunctive judgment, and the determination of either part would determine the other.

On these three points of a judgment we touch but lightly here, because they affect the laws of Formal Logic, and are therefore more fully considered in another place.

Modality.

(25). Modality concerns the manner in which we think a judgment with regard to its truth, and is divided into the three moments of Problematical, Assertive, and Necessary. The first degree of holding true is that of problematical, which merely signifies the possibility of the judgment, inasmuch as it does not violate any of the universal laws of thinking.

The second degree accords to a judgment the agreement with the matter of the senses, as well as with their necessary forms. The third degree makes some *à priori* law of thinking the matter of the judgment.

A problematical judgment merely implies a formal, but not a material possibility. For instance, the conception of an elderly lady riding through the air on a broomstick, is formally possible, as it involves no contradiction, but is not generally considered materially possible.

A judgment may be assertive without its contents having come immediately under the

cognizance of the person who forms it. Nothing more is meant by the above definition, than that assertive judgments must have sufficient and empirical grounds for their truth.

The third moment, Necessity, is applicable to any *à priori* law, whether rational, intellectual, or intuitive. For instance, that A is C, if A is B, and B is C, is a necessary truth of reason. That no change in phenomena can be self-originated, or that every effect must have its cause, is a necessary truth of the understanding. That the straight line is the shortest between two given points, is a necessary truth of intuition.

(26.) Propositions are judgments whose modality is either assertive or necessary: for a problematical judgment, so far as its modality alone is concerned,* merely implies that a certain judgment is not necessarily false, but bears no positive testimony to its truth. And we could not therefore say with propriety that any thing is *proposed* in a problematical judg-

* It was necessary to introduce this restrictive clause; for problematical judgments, considered independently of their modality, are generally intended to imply some anticipation of a truth, and their main use is as a step to the assertive. For instance, there may be such a person as Mr. Stiggins in New York, but no man would ever make such a judgment unless he had some grounds for believing it true.

ment, as that term has evidently a positive signification.

Propositions alone can enter into the consideration of Formal Logic; for the laws of Reason require something determinate for the matter of the judgments whose combinations they regulate, and are not conversant about mere possibilities which have only a negative value in relation to truth. This science moreover regards all propositions as assertive: for it cannot admit the distinction between assertive and necessary modality, as this is determined by the matter of judgments, and is quite independent of their form.

Synthetical and Analytical Judgments.

(27.) Judgments may be divided, as to their matter, into Synthetical and Analytical.

Synthetical judgments are those whose predicates are not contained in the conception of their subjects.

Analytical judgments, on the other hand, predicate of their subjects something that is already contained in them, or, in other words, their predicate is a superior conception to their subject.

Hence we see that synthesis, or the principle of synthetical judgments is the conjunction of

two different cognitions, neither of which is contained in the other.

Analysis, or the principle of analytical judgments, is the dissection of a conception into its partial representations.

As the matter contained in the conceptions of the subject and predicate determine the nature of the judgment in respect of the above division, it follows that the same proposition may express an analytical judgment to one person, and a synthetical judgment to another. The proposition 'all members of the University are members of some particular college,' is an analytical judgment to a person who is well acquainted with the constitution of the University, and whose conception of a member of the University already contains the conception of his belonging to some particular college. But the same proposition is synthetical to a person who is entirely ignorant of that constitution, and is therefore unacquainted with the necessary conditions to being a member of the University.

(28.) But the most remarkable instance of confusion between synthesis and analysis arises from the circumstance, that what is analysis considered objectively, is very frequently a synthesis if considered subjectively. Thus the process by which a chemist examines any

substance for the purpose of discovering its qualities, is rightly named analysis when referred to the object examined, but is synthesis when considered in relation to himself. For instance, if a person, who is perfectly ignorant of the constituent elements of water, separates the two gases by means of some chemical process, the investigation is correctly styled analysis, if considered in reference to the object 'water,' as he has disjoined its component parts: but the result in the operator's own mind is a synthesis; for his previous conception of water contained nothing more than fluidity, the absence of all colour and taste, and perhaps the property of dissolving a great many salts. But by the analysis of the object he has increased this conception, by adding to it, that water is composed of oxygen and hydrogen; and consequently his mental act is a synthesis.

Definition.

(29.) Definition is a judgment which determines all the partial representations contained in any conception, and is therefore equivalent to a completed analysis.

There is a specious resemblance of definition which is grounded on a synthesis, and has really no right to the name.

Definition, in the strict acceptation of the word, regards only the matter of a conception, and not its sphere. But sometimes the term is improperly applied to the exposition of any conception whose sphere is the same with that of the conception to be defined. Let us suppose that a conception *a b*, or one which contains the partial representations *a* and *b*, is connected by a certain law with the conception *c d*, and in such a manner that the sphere of *a b* is identical with the sphere of *c d*. In this case it would not be a correct definition of the conception *a b*, to state that it contained the partial representations *c* and *d*; though such a judgment would lead us to the same individuals as if the correct definition had been given. Such a judgment would be a true synthetical judgment, but not a definition.

(30.) It follows from this, that two persons may give different definitions of the same thing, and yet both of them be equally correct: for though the things be the same in each case, yet the conceptions by which each individual may recognise these things may be very different, and perhaps have hardly a single point in common. Let us take as an example the conception of water. The common conception contains little more than that water

is a perfectly tasteless and colourless liquid. Now these properties are connected by a law of nature with a combination of oxygen and hydrogen, in certain proportions and under certain circumstances; and a definition which contained either account of water would equally refer to the same thing, but to very different conceptions. The rustic would probably not have much faith in the chemist's proof that a certain liquid was water by his exhibiting the gases in a separate state; neither would the chemist have much faith in the rustic's definition: and yet the definition would be correct in each case, as it would express that conception by which each was in the habit of recognising the thing itself. The example in Mr. Newman's Logic is a very good one. He observes that it would be extremely incorrect to define man as a cooking animal, although it is highly probable that man, and man only, answers to that description. But as we do not recognise men by this peculiarity in their nature—in short, as it does not form part of our conception of humanity, such a definition would only mark out the sphere, and by no means determine the matter of our conception of man. When two conceptions are united by some law which is immediately and universally recognised, it becomes a matter of indif-

ference from which of these conceptions we derive our definition. For instance, the common definition of a triangle is 'a figure of three sides,' whereas in strictness it should be 'a figure of three angles.' The usual definition is in reality a pure synthetical judgment of intuition.

FORMAL LOGIC.

BOOK I.

SECTION I.

PROPOSITIONS.

(30.) Propositions are of three kinds—Categorical, Hypothetical, and Disjunctive.

Form of Categorical Propositions.

Categorical propositions consist of two terms and a copula, of which the terms designate the matter, and the copula their relation to each other. Their most general form may be represented by the proposition 'A is B,' in which the terms A and B are connected by the copula 'is.' Particular examples are, 'horses are animals,' 'men are not monkies.'

Many categorical propositions do not come immediately under this simple form, but are easily reduced to it by a periphrasis; *e. g.* the proposition 'I took a ride this morning'

may be put under the form, 'I am a person who took a ride this morning.'

The terms are susceptible of no other* formal variations than the moments of quantity, which determine to how much of the sphere of a conception the proposition refers.

There can be only two such formal variations—the whole, and less than the whole, or part. For we evidently cannot speak of more than the whole, as the idea involves an absurdity: neither can we make any distinction between different quantities that are less than the whole, without introducing the consideration of the matter of a conception as well as of its form. It follows, therefore, that 'the whole' and 'less than the whole' are the only variations of quantity which Formal Logic can recognise: *e. g.* we may speak of 'all albinos,' *i. e.* the whole sphere of the conception 'albino,'

* It is sometimes convenient to consider the matter of a proposition with respect to its quality as well as quantity, and to speak of 'not A,' 'not B,' &c.: in this case, the 'not A' is called the external sphere of A. The attribute of quality is, however, but rarely accorded to the terms: for if the predicate is an external sphere, the form of the proposition is precisely the same as if the negation had been applied to the copula. Thus, A is a 'not B' is exactly equivalent to A 'is not' B. And an external sphere is but rarely introduced in the subject for other reasons, as well as on account of its extreme awkwardness. For instance, we do not say, 'not men' are 'not Englishmen,' but 'all Englishmen are men,' though the meaning of the two propositions is precisely the same.

or of 'some albinos,' *i. e.* a part of the sphere of that conception.

When the whole of either term is compared with the other, it is said to be distributed; when a part only is so compared, it is said to be undistributed. For instance, in the proposition 'All A is B,' the term A is distributed; but in the proposition 'Some A is B,' it is undistributed.

The only formal variations of which the copula is susceptible, are two moments of quality, affirmation, and negation. For if we compare any two terms A and B in a categorical proposition, we can only affirm or deny the one of the other: *e. g.* A is B, A is not B. In the first example the quality is said to be affirmative, in the latter negative.

Hence, the two terms and the copula, which constitute the three elements of a categorical proposition, severally admit of two gradations or variations in form: and if there were no law for their limitation, the number of possible combinations of these elements would $= 2^3 = 8$. These eight combinations would be,

* All A is Some B.	All A is All B.
* Some A is Some B.	Some A is All B.
* All A is not All B.	All A is not Some B.
* Some A is not All B.	Some A is not Some B.

(32.) But we find by experience, that of these eight forms of categorical propositions, only four are ever introduced in practice: for the quantity of the term that is placed last in the general categorical form (*i.e.* A is B) is entirely determined by the quality of the copula.* The variations of the copula and of this latter term must therefore be taken together, and the whole number of combinations for categorical propositions will $= 2^2 = 4$.

As the first and last† terms of a categorical proposition do not bear precisely the same relation to the copula, independently of their mere position, they are distinguished respectively by the names of *subject* and *predicate:*

* The law for the dependence of the quantity of the predicate upon the quality of the copula, can only be assumed in Formal Logic: for the *à priori* grounds upon which it rests are to be found in the consideration of one of the categories or conceptions of the understanding, and therefore belong to the Transcendental branch of the science. This subject will be considered in a future section, but a cursory view of it may not be wholly out of place here. The category of substance can never be introduced in the predicate of any proposition, and this term must therefore be a conception. But the quantum of the sphere of a conception is entirely indeterminate, as there is no formal limit to the number of individuals that may answer its conditions. It is therefore impossible to compare the limits of the sphere of the predicate with those of the subject, as those of the former are unknown. The subject then can only be placed wholly out of, or wholly in, the sphere of the predicate, and the latter will be distributed or undistributed accordingly.

† *i.e.* the first and last in the simplest form of a categorical proposition, *e.g.* 'All A is B.'

and the propriety of introducing such a distinction into Formal Logic depends entirely on this formal difference of relation, and not at all on the real nature of the distinction, which is a subject of Transcendental Logic, and cannot therefore be considered here. Neither does it at all depend on the order in which the terms are arranged; * for this is frequently reversed in some languages, and occasionally even in English.

Of the eight combinations given in the last page, those marked by an asterisk are the four legitimate Categorical propositions. As, however, the quantity of the predicate is a known function of the quality of the copula, it is never expressed, but always understood; the four propositions will therefore assume the following form:

All A is B.	No A is B.
Some A is B.	Some A is not B;

where it must be observed that the proposition 'No A is B' is equivalent to the proposition

* This order is seldom introduced in English, except in poetry, emphatic diction, or where the subject is a sentence. The following are examples of these three cases:

"Oh, many are the Poets that are sown
By Nature!—*Wordsworth.*

i. e. the poets are many that, &c. "Brave indeed is that man who," &c. *i. e.* that man who, &c. is brave indeed. "It is very easy to say a great deal in a letter that cannot be hinted at in a personal interview," *i. e.* to say a great deal in a letter, &c. is very easy.

'All A is not B,' or the entire exclusion of A from B.

As the difference in form of these four propositions arises from variations in the subject and copula, they will admit of two corresponding co-divisions. One of these is into Universal and Particular, and respects the quantity of the subject; the other is into Affirmative and Negative, and respects the quantity of the copula. They are thus divided into Universal Affirmative represented by A; Universal Negative by E; Particular Affirmative by I; and Particular Negative by O:

	AFFIRMATIVE.	NEGATIVE.
Universal.	A. All A is B.	E. No A is B.
Particular.	I. Some A is B.	O. Some A is not B.

(33.) The law by which the number of legitimate combinations is reduced to four, may be stated as follows:

Affirmative copulas have undistributed predicates; Negative copulas have distributed predicates. For if B is predicated of A, A is subsumed under the conception B as being a part of its sphere; for instance, in the pro-

position 'all horses are animals:' the subject 'horses' is subsumed under the conception of the predicate 'animals,' as being a part of the sphere of that conception. But it is evident that the proposition does not refer to the whole sphere of the conception 'animals,' for in that case there could be no other animals than horses.

The annexed diagram is a general illustration of the law:

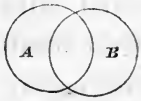
All A is B. Some A is B.

In each of these diagrams we see that A is compared with only a part of B; that is to say, B is undistributed.

It frequently happens that the sphere of the predicate is not any larger than the sphere of the subject: this however is incidental, and can only arise from the peculiar nature of the matter of the proposition, and never from its logical form: for in the example 'all carnivorous animals have teeth of a certain form,' it may be equally true that 'all animals with teeth of this form are carnivorous.' But the latter proposition requires additional knowledge of the subject matter, and cannot be deduced from the mere form of the original statement.

If, on the other hand, the predicate B is denied of the subject A, the sphere of A is entirely excluded from the whole sphere of B: for instance, in the proposition 'no durable friendship can be based on a participation in crime,' friendship is entirely excluded from all those things which can be based on a participation in crime: or in the particular proposition 'some of the most talented men do not possess the best private characters; these 'some men' are entirely excluded from all who possess the best private characters. In each case then the predicate is distributed, as the proposition refers to the whole of its sphere. The diagrams will take the following forms:

No A is B



Some A is not B

in which it is evident that the whole of B lies out of as much of A as is introduced in the subject.

The accompanying table contains the results of these remarks:

		SUBJECTS.	PREDICATES.
Universal Affirmative	A ...	Distributed	— Undistributed.
Particular Affirmative	I ...	Undistributed	— Undistributed.
Universal Negative	E ...	Distributed	— Distributed.
Particular Negative	O ...	Undistributed	— Distributed.

SECTION II.

MUTUAL RELATIONS OF CATEGORICAL PROPOSITIONS.

(34.) The mutual relations of the four propositions A, E, I, O, have been usually classed by logicians under the generic term of Opposition. But as there is no opposition whatever in some of these relations, it may be more correct to restrict the acceptation of the word to those cases which contain its meaning, and apply that of Subalternation to the rest.

Opposition.

Opposition is of three kinds—Contradictory, Contrary, and Sub-contrary.

Contradictory opposition is the relation which exists between two propositions that simply contradict each other. One of them therefore must be false, and the other true. For each of them must be either true or false, and if one of them is true, the other which asserts that it is false, must be itself false; and if one of them is false, the other which asserts that it is false, must be itself true.

Contradictories differ from each other in the quality of their copulas; for as one denies

what the other asserts, the former must be affirmative, and the latter negative.

They differ also in the quantity of their subjects. For a contradictory contains nothing more than the falsity of that proposition to which it is opposed, and must therefore express the change that takes place in the relation of the terms, when its opposite first ceases to be true. But the first formal change affecting the truth of an universal proposition, affects only a part of its subject; as that cannot be true of the whole, which is false of a part. And the first formal change affecting the truth of a particular proposition, must necessarily affect the whole of the subject; as that cannot be false of every part, which is not at the same time false of the whole.

These remarks will be better understood by the assistance of the accompanying diagrams:

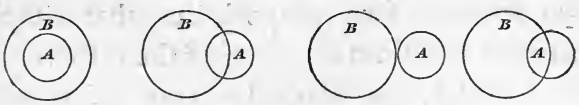


Fig. 1. *a.* Fig. 1. *b.* Fig. 2. *a.* Fig. 2. *b.*

Fig. 1. *a,* represents the proposition, All A is B; and Fig. 2. *a,* represents the proposition, No A is B. Now it is very evident that the first changes which will render these propositions no longer true, must take place when the sphere of A first begins to emerge from

that of B, as in Fig. 1. *b*, or when it first begins to impinge on it, as in Fig. 2. *b*. And the propositions which express these changes must necessarily be the respective contradictories of the original propositions. 'Some A is not B' will therefore contradict the proposition 'All A is B,' and 'Some A is B,' the proposition 'No A is B.' Contradictories are therefore opposed to each other both in quality and quantity: the universal affirmative A is opposed to the particular negative O; and the universal negative E, to the particular affirmative I. Example: 'Some Englishmen are as light-hearted as Frenchmen;' 'No Englishmen are as light-hearted as Frenchmen.'

(35.) Contrary opposition exists between two propositions which contain each other's contradictory, and something more besides. Hence it follows that they cannot be both true, but may be both false: for if one is false, that part of its contrary which merely contradicts it, must be itself true; but the other part, or surplus statement, may be either true or false.

As contraries state more than each other's contradictories, the quantity of their subjects must be greater, and therefore distributed; whence it follows that A and E are the only propositions between which this species of opposition exists. Examples of this opposition are—'All smuggling is dishonest'; 'No

smuggling is dishonest.' 'All Englishmen are haughty'; 'No Englishmen are haughty,' &c.

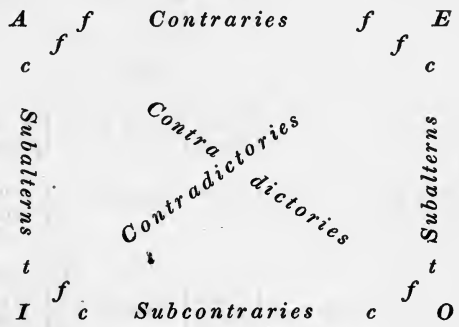
(36.) Subcontrary opposition, as its name in some measure indicates, is the opposition of propositions contained under contraries. The subjects of the subcontraries must of course be less than the subjects of the contraries which contain them, and are therefore undistributed. As I and O the sub-contraries are contradictories of the two contraries E and A, and as the contraries cannot be both true, but may be both false, it follows that the subcontraries may be both true, but cannot be both false. Examples are, 'Some men are liars'; 'Some men are not liars': both of which are true. 'Some men are perfect'; 'Some men are not perfect': of which propositions one is false.

Subalternation.

(37.) Subalternation is the relation which exists between an universal proposition, and the particular that is contained in it. The former is usually called the Subalternant, the latter the Subalternate.

The truth of the subalternant necessarily involves the truth of its subalternate, as what is true of the whole, must be also true of a part; and the falsity of the subalternate involves the falsity of the subalternant, as what

is false of a part cannot be true of the whole. But the converse of these propositions does not hold; for what is true of a part, is not necessarily true of the whole, and what is false of the whole, is not necessarily false of a part. Hence, we cannot infer the truth of the universal from that of the particular subalternate to it, nor the falsity of the particular from that of its subalternant universal. Examples are—'All dogs are animals,' whence it follows, 'Some dogs are animals.' 'Some politicians are no better than they should be,' whence it cannot be logically inferred that 'All politicians are no better than they should be.' The annexed scheme is usually employed to elucidate the relations of categorical propositions:—



f means false; *t* means true; and *c* contingent.

The letters *f*, *f*, *c*, that are placed against the Universal Affirmative A, are intended to

represent that A is false when E or O are true, and contingent when I is true, and similarly of the rest of the table.

Perhaps the following table is more immediately intelligible —

			If one is	The other is
Opposition.	Contradictions.	Between A and O.	True	False.
			False	True.
		Between E and I..	True	False.
			False	True.
	Contrary.	Between A and E.	True	False.
			False	Contingent.
	Subcontrary.	Between I and O.	False	True.
			True	Contingent.

Subalternation.	Between A & I.	If A is	True / False	Then I is...	True.	
					Contingent.	
		If I is	True / False	Then A is..	Contingent.	
					False.	
	Between E & O.	If E is	True / False	Then O is..	True.	
					Contingent.	
		If O is	True / False	Then E is..	Contingent.	
					False.	

Conversion.

(38.) Conversion is the transposition of the terms of a proposition, in such a manner that the subject becomes the predicate, and the predicate the subject. Conversion is of two kinds, simple and limited. The former is the simple transposition of the terms, retaining the previous quantities; the latter requires the limitation of the subject.

In all conversion, no term must be distributed in the converted proposition, that is not distributed in the original proposition: hence E and I are simply convertible, as in E both terms are distributed, and in I, neither. No term then is distributed in the converted proposition, that was not previously distributed in the original proposition. But A is not simply convertible, as its predicate is undistributed, and would become distributed by simple conversion. It admits however of limited conversion, and then becomes I; for in I, no terms are distributed, and therefore none can be distributed in it, which are undistributed in the original proposition. E may also be converted by limitation, as well as simply, and then becomes O. O can never be converted, as its subject is undistributed, and therefore can never become the predicate of

a negative proposition, which is always distributed.

CONVERSION.

Simple.	Limited.
E..... to .. ...E	A..... to I
I... ... to I	E..... to .....O

Examples :—

No cats are cows.	All dogs are animals.
No cows are cats.	Some animals are dogs.

SECTION III.

HYPOTHETICAL AND DISJUNCTIVE PROPOSITIONS.

(39.) An hypothetical proposition consists of two judgments and a copula.

The judgments constitute the matter of the proposition, and the copula expresses their relation, or that function of the understanding by which they are conjoined in one consciousness.

The whole proposition represents that one of these judgments which is called the antecedent, contains all the necessary grounds for the truth of the other, which is accordingly called the consequent.

The most general form of these propositions is the following. 'If A is B, C is D,' in which the judgment 'A is B' is the antecedent, 'C is D' the consequent, and the word 'if' the copula.

(40.) As an hypothetical proposition merely asserts such a connexion between two judgments, that the truth of the one may always

be inferred from the truth of the other,* it follows that both the form and the matter of these judgments constitute the matter alone of the hypothetical, and cannot be the means of introducing any variations into its form. Neither can such variations arise from the form of the copula; for the conception of a law connecting a consequent with its grounds, may be thought, or not thought, with regard to any judgments, but will neither admit of a negative quality, or of a quantum or degree. Hence there is but one form for hypothetical propositions, and all the variations that take place in them must be considered as affecting their matter alone. For instance, the proposition 'if some A is B, some C is D,' does not differ in form from the proposition 'if all A is B, all C is D.' It is true that the categorical judgments in these examples have formal differences, as in the former they are both particular, and in the latter both universal. But in either case, such a relation is asserted to exist between them, that the truth of the one must be the invariable consequence

* The understanding merely asserts a relation of such a nature between the judgments that the truth of the one *may* be inferred from that of the other. But in order that this result should be *actually* inferred, another judgment is necessary which shall assert the truth of the antecedent, and then the *reason* will deduce the truth of the consequent.

of the truth of the other; and it is this universality alone, and not that of the judgments themselves, with which the form of an hypothetical proposition is concerned.

(41.) From these observations it will readily be seen that an hypothetical proposition cannot have an hypothetical contradictory: for a contradictory states nothing more than the falsity of that proposition to which it is opposed, and, if this latter is an hypothetical, merely denies that there is any law by which the truth of the consequent can be rightly inferred from that of the antecedent. But this does not establish any similar relation between any other two judgments, and is not therefore hypothetical in its nature. The contradictory must accordingly be a categorical proposition, in which I predicate of my consciousness, that it does not give objective validity to such a relation between two judgments, that one contains the grounds for the other.

(42.) Many logicians have considered the hypothetical proposition as merely another form of a categorical; and this error has been rather favoured by the seeming ease with which an hypothetical may be put under such a categorical form as shall answer all the logical ends of the original proposition. But the two propositions have been shewn by

Kant to be based on fundamentally different acts of the understanding, which ought never to be confounded with each other. For instance, the hypothetical proposition 'if A is, B is,' appears to be fully expressed in the categorical form, 'all the cases of A being, are cases of B being;' and so far as any logical deductions from either one or the other are concerned, the propositions are equivalent. But there is this fundamental difference between them: the former represents the dependence of one judgment upon grounds contained in the other, and therefore enunciates a law to which the understanding has accorded its assent as being universally valid; whereas the latter form either merely asserts the fact 'that all the cases of A being are cases of B being,' without superadding the conception that they are so universally by a law; or else, if it means that 'all possible cases of A being are necessarily cases of B being,' it has only placed what constituted the form in the hypothetical proposition in the matter of the categorical, but has by no means transfused the virtue of the form of the one into the form of the other. In fact, this method is no more a formal reduction of an hypothetical to a categorical proposition, than if we merely said, "the hypothetical proposition 'if A is, B is,' is true."

Disjunctive Propositions.

(43.) Disjunctive propositions consist of any number of judgments, which they disjoin in the relation of reciprocal dependence. Hence the whole conception of their possibility is divided between them, and the truth of either may be inferred from the falsity of the others, or inversely, the falsity of all the others from the truth of one. Their general form is 'either A is B, or C is D.' All the observations that have been made on hypothetical propositions, in order to prove the impossibility of any variations in their form, apply with equal force to the disjunctive: and as the disjunctive expresses a distinct function of thinking, any attempt to bring it into a categorical form will meet with no better success than in the case of hypotheticals. It is true that we can express the meaning of a disjunctive in a categorical form; but then, what constitutes the form in the one proposition must be introduced in the matter of the other. For instance, the disjunctive proposition 'A is either B or C' may be expressed thus: 'the cases of A being B are identical with the cases of A being not C.' But here we see that the completeness of the division, which is the real principle of disjunctive propositions, is expressed in the conception of the identity of

one judgment with the negation of another, which constitutes the matter of the categorical proposition. And hence, as in the case of the hypothetical, we have no more succeeded in the transformation of the disjunctive to the categorical form than, if we had said, "the proposition 'A is either B or C' is true."

(44.) Disjunctives resemble hypothetical propositions in not admitting a contradictory of the same form with themselves: for the contradictory of a disjunctive must merely contain the falsity of that proposition, and therefore denies that a certain cognition is exactly divided out among the members of the disjunction, but by no means gives a new and correct division. Hence the contradictories to both these forms of propositions are simply categorical in their nature.

SECTION IV.

SYLLOGISM.

(45.) Kant has defined syllogism as that function of thinking by which we derive one judgment from another, and has in this manner included all those judgments which may be formally derived from another single judgment by the methods of opposition, subalternation, &c.

These syllogisms, styled *immediate* from their wanting a middle term, he arranges under the title of syllogisms of the understanding, and the propriety of such a classification, as far as the meaning alone is concerned, is evident from the nature of the faculty employed. But as it is rather questionable whether the derivation of the word will bear out this general acceptation, we shall follow the usual practice of logicians, and restrict its signification to those syllogisms which Kant defines as the syllogisms of reason.

Syllogism, then, is that function of the reason by which a third judgment is derived

from the union of two others, neither of which contain it when taken separately.

(46.) The first division of which syllogism is susceptible, is determined by the nature of the judgments in respect of their moments of relation. These have already been shewn to be three—the categorical, hypothetical, and disjunctive; and as there are a great many combinations of judgments of these several moments, from all of which other judgments may be deduced, it follows that there must also be a great many different syllogistic forms of ratiocination. But as the principles involved in all of them are the same as those in the three simplest forms (which are usually named after the three moments), it will be sufficient to investigate the laws which regulate these alone, and, with one or two exceptions, leave the consideration of the rest to the ingenuity of the reader. In these three species of syllogism, the categorical, the hypothetical, and the disjunctive, a categorical conclusion is deduced from one judgment of categorical form, and another of that form from which the syllogism takes its name. We shall now proceed to the separate consideration of each of these three forms of reasoning.

Categorical Syllogism.

(47.) In this syllogism the two given judgments, which are also called premises, and the derived judgment or conclusion, are all categorical propositions. The nature of this species of argument may be popularly stated as follows: 'If two cognitions are severally compared with a third cognition, (that is, objectively the same in each case,*) they may afterwards be compared† with one another.‡

* Perhaps an objection may be brought against this exposition, on the grounds of its admitting negative premises. But it must be observed that when both premises are of this quality, the real middle is an external sphere, and consequently undistributed, or virtually two middles. And this fallacy is quite excluded by the clause in parentheses.

† The affirming or denying one cognition of another is what is here intended by comparison. For if two cognitions are referred to the consciousness simultaneously, they must either be thought as belonging to the same subject or substratum, in which case one may be affirmed of the other; or as not belonging to the same, in which case one may be denied of the other.

‡ As it is our present object to discover the universal laws of all categorical syllogism, we have preferred this simple though not very elegant definition to the celebrated '*dictum de omni aut nullo*' of Aristotle, which is merely a particular case of it, and may be stated thus: 'What is affirmed or denied of all, is affirmed or denied of each;' but this would only have given a particular class of categorical syllogisms, and is therefore insufficient for our present purpose. Were we however to admit either the empirical considerations of the use of the reason, or the metaphysical considerations of the conceptions of the understanding, we should then be justified in confining our attention to the dictum alone. For in the actual use of the reason we discover the fact, that this form of syllogistic ratiocination is at once more natural

This is the principle of all categorical syllogism; and whenever the conditions are really answered, and the comparison made according to certain laws which we are about to determine, the conclusion is necessary, and the reasoning incontrovertible. Let us take as an example, 'Animals of the same species are supposed to have originated from the same pair; all dogs are animals of the same species, therefore all dogs are supposed to have originated from the same pair.' Here, dogs and animals supposed to have originated from the same pair, are severally compared with animals of the same species, and are afterwards compared with one another.

(48.) We must now determine those laws, in conformity with which the various forms of categorical propositions may be so combined as to answer the required conditions of syllogism.

For this purpose we must not give a mere aggregate of rules, even though those rules should be in themselves sufficient. This method, which has been adopted in most (if not

and intelligible than the rest, and in the nature of one of the conceptions of the understanding, we can discover the reason of the fact. But we must not regard what lies out of the field of Formal Logic, and have therefore given a definition which will include all the forms of categorical syllogism that are possible in theory, however awkward some of them may be in practice.

all) works on Logic, is exceedingly unscientific, as it only shews that certain rules are requisite and sufficient to provide against certain forms of paralogism, but by no means proves that these are the only forms to which a syllogism is exposed. Now the method of exhaustion will secure our reasoning against all fallacy, so far at least as mere Formal Logic is concerned.* We shall therefore dissect categorical syllogism into its ultimate elements, and discover what rules are necessary and sufficient for the prevention of fallacy in each of them.

(49.) Every categorical syllogism contains three terms—the major term, the minor term, and the middle term; and three propositions—the major premiss, the minor premiss, and the conclusion. In the major premiss, the major term is compared with the middle term. In

* It may be as well to notice here, the very prevalent custom of introducing into treatises on Logic, the consideration of material as well as formal fallacies. In all the works on this science that have come under our observation, (with the exception at least of Kant's,) nearly the first rule for syllogism is to the effect that the middle term must not have different meanings in the two premises. Now Logic merely considers the formal laws of reasoning, but has nothing whatever to do with its matter; and the introduction of such a rule as this in a work on that science, is something like beginning a treatise on Geometry with an injunction to the student to draw his circles correctly: as if mathematical reasoning could be at all affected by the perfection of the diagram.

the minor premiss, the minor term is compared with the middle term. And in the conclusion, the major and minor are compared together. The major term is always the predicate, and the minor the subject of the conclusion. Hence may be deduced the following rules for distinguishing the different terms and premises in any given syllogism :—

1st. The term that is common to the two premises is the middle term.

2nd. The term that is the predicate of the conclusion is the major term; and the premiss that contains it, the major premiss.

3rd. The term that is the subject of the conclusion is the minor term; and the premiss that contains it, the minor premiss.

The three propositions are usually placed in the following order: the major premiss, the minor premiss, and the conclusion. And the particular form of a syllogism, as far as it depends on the particular categorical forms of its three propositions, is termed its mood: though this name is also given to any ternary combination of the symbols A, E, I, O, without reference to its conformity to the syllogistic laws.

(50.) For the simplification of the subject

we shall divide it into the three following questions:—

1st. What forms of premiss are sufficient for a conclusion of the reason,* without considering its capability of being expressed in any of the four categorical forms, (*i.e.* A, E, I, O)?

2nd. When can the conclusion be expressed in any of the legitimate forms, and when can it not?

3rd. What laws are sufficient and necessary to secure the legitimacy of the conclusion?

As the first of these questions excludes all reference to the categorical form of the conclusion, and only seeks for premises that give a conclusion valid for the reason, it does away with the distinction of subject and predicate, so far as the conclusion is concerned; and therefore with the distinction of major and minor premiss. Hence, in this part of our investigation, both premises are on exactly the same footing.

* As it is impossible that the reader should understand the following pages, unless he has a clear conception of what is meant by a conclusion 'possible for the reason, but not expressible in any of the four legitimate categorical forms,' we subjoin the following example. If the premises are 'some B is A, some C is not B,' the reason may logically deduce that some C is not some A. But this conclusion is not in one of the four legitimate forms, and is therefore styled a conclusion only for the reason.

We may also discard all considerations of the extremes. For any peculiarities in the form of these terms, can merely require corresponding peculiarities when they recur in the conclusion, as they constitute the matter only of that judgment. They may therefore affect the nature of the conclusion, but cannot affect the possibility of its existence.

All that remains then for our consideration, is the middle term, and the copula in both the premises.

(51.) Now the middle term admits of no variations but those of quantity. Every law therefore regarding it must respect this, and this alone. And we find accordingly that the middle term must be distributed in at least one of the premises.

For if the middle term is undistributed, a part of it only is compared with each premiss. And as it cannot be formally known that the major and minor are compared with the same parts, the middle term becomes virtually two terms, and the major and minor terms cannot be considered as formally compared with the same. But it is not necessary that the middle term should be distributed in more than one premiss. For if the whole middle term is compared with one of the extremes in one premiss, and only a part of it

with the other extreme in the other premiss, that part must be compared with both extremes, and in this case therefore the middle term cannot be considered as two terms, or ambiguous.

(52.) The first law for the quality of the premises may be derived from the law for the distribution of the middle term. This could not be the case if every possible comparison of the spheres of two terms, both internal and external, positive and negative, found a corresponding expression among the categorical forms: for in that case, a law regarding quantity could not affect quality. This however has been shewn not to be the case, as external spheres are never made subjects; and hence arises the possibility of deducing from the law for the distribution of the middle term the following law for the quality of the premises.

No conclusion is possible from two negative premises. For in premises of this form, the extremes are each placed in the external sphere of as much of the middle term as is compared with them, and consequently the external sphere becomes the real term with which both extremes are compared. But the external sphere is not distributed in any categorical form, and consequently the virtual

middle term would be undistributed, and no conclusion possible.

No. B is A. No. C is B.

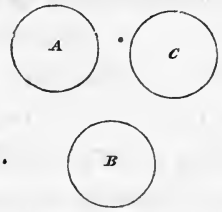


Fig. 1.

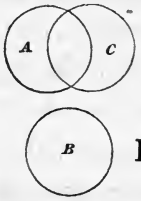

Fig. 2.

In the accompanying diagram we see that A and C are each placed in the external sphere of B; but as the external sphere is undistributed in both propositions, we do not know that A and C are compared with the same parts of it, and cannot therefore compare them with one another. In Fig. 1. we find that 'no C is A,' and in Fig. 2. the contradictory 'some C is A.'

As the external spheres of conceptions do not admit the variations of quantity, or bear the same mutual relations in any categorical propositions as the internal spheres, they are never understood unless they are expressly mentioned. It is for this reason that the law for the distribution of the middle term is generally understood to relate to the internal spheres only, and that the law against two negative premises cannot be subsumed under it as a particular case. It is therefore given

as a separate law, that at least one premiss must be affirmative.

The extreme term contained in the affirmative premiss will of course agree and coincide with the middle term, and will therefore agree or disagree with all with which the middle term agrees or disagrees in the other premiss. Hence the latter premise may be either affirmative or negative, and there is no other law for the quality of the premises, than that given above.

(53.) We have now exhausted the elements of the premises, (for we have shewn that our present inquiry does not involve the distinction of the premises, or the consideration of the major and minor terms,) and have arrived at the following laws for the middle term, and the quality of the two copulas.

In order that a conclusion for the reason, though not necessarily categorically expressible, be possible from any particular forms of premises, it is only necessary—

1st. That these categorical forms contain at least one distributed term.

2nd. That one of these forms be affirmative.

As at present there is no distinction between the premises, we are not considering permutations but combinations; and as each proposition may be combined with itself, the number will

be $\frac{5 \cdot 4}{1 \cdot 2} = 10$, of which we shall find by the following table, that 6 are unobjectionable, that 3 are excluded by their negative premises, and 1 by the want of a distributed term.

	Conclusion.	Forms of premises from which no conclusion is possible.		Forms of premises from which a conclusion at least for the reason, is possible.
		No distributed term.	No affirmative term.	
A combined with	A	——	——	A A
	E	——	——	A E
	I	——	——	A I
	O	——	——	A O
E combined with	E	——	E E	——
	I	——	——	E I
	O	——	E O	——
I combined with	I	I I	——	——
	O	——	——	I O
O combined with...	O	——	O O	——

The above table is only intended to state, that some conclusion, though perhaps not categorically expressible, is sometimes possible in each of the six forms in the last column, but always impossible in the four forms in the other two columns. And it must be observed that we can only say sometimes possible; for though all these six forms contain one or more distributed terms, yet if the middle is not one of those terms, it will be undistributed, and no conclusion possible. For

instance, let B be the middle term, and A I the form of the premises, if we say 'All B is A,' 'Some C is B,' the conclusion that 'Some C is A,' is strictly deducible. But if we say 'All A is B,' 'Some C is B,' therefore 'Some C is A,' our conclusion would not be logically correct, as the middle term B would be undistributed in each premiss. We repeat, therefore, that the last table merely indicates the possibility of deducing a conclusion for the reason from some premises of certain forms, and the impossibility of deducing any conclusion whatever from premises of certain other forms.

(54.) We may now dismiss the first part of our present investigation, and consider the second question. When can the conclusion be expressed in any of the legitimate forms, and when can it not?

As the variations of quality have not been allowed to affect the terms * in the categorical forms of the admissible premises, the conclusion from them that is possible for the reason, but not categorically expressible, cannot be so restricted, on account of its being valid for

* Perhaps the following explanation will be more easily understood than the text. As external spheres have not been admitted as terms in the forms of premises given in the above table, it is impossible that they should appear in the conclusion; the impracticability therefore of these conclusions cannot arise from the appearance of an external sphere in either of their terms.

only the external sphere of a conception. It must therefore belong to one of the four rejected forms (mentioned in Art. 32,) whose predicates do not as functions of the copula follow the same law with the accepted forms. In other words, the conclusion must belong to one of these four forms, in which the predicate of an affirmative is distributed, and of a negative undistributed. But it cannot belong to a proposition of the former class, as in that case one of the legitimate categorical propositions, in which the predicate is undistributed, would state less than this sound conclusion, and would therefore be contained in it, and be itself true; but this is contrary to the hypothesis. Hence the only case that remains in which a conclusion can be valid for the reason, but not categorically expressible, is when a conclusion whose quality is negative has a predicate whose quantity ought to be undistributed. And we shall accordingly find that the rule for the quantity of the predicate of the conclusion will exclude all those premises which give conclusions only possible for the reason.

(55.) Our next object is to determine what laws are sufficient and necessary to secure the legitimacy of the conclusion.

For this, let us examine the three elements

of the conclusion—the subject, the predicate, and the copula.

As the only variations of which the terms admit are those of quantity, the laws concerning them must respect that, and that only.

As, moreover, logic can only consider the formal quantity of a term, either extreme may contain in the conclusion the same quantity as in its premiss, but not more. Hence the only rule for the terms is this:

If the major or minor terms are undistributed in the premises, the predicate and subject must be respectively undistributed in the conclusion.

When this rule is violated in a syllogism whose major term is undistributed in the major premiss, but whose predicate is distributed in the conclusion, the resulting fallacy is called an illicit process of the major.

When the minor term is undistributed in the minor premiss, and the subject is distributed in the conclusion, the resulting fallacy is called an illicit process of the minor.

(56.) With regard to the quality of the copula, the only law for the conclusion is this:

If either premiss be negative, the conclusion must also be negative; but if both premises are affirmative, the conclusion must also be affirmative.

For as one premiss must be affirmative, the extreme term which it contains must agree with the middle term in that premiss, and therefore agrees or disagrees in the conclusion, with whatever the middle term agrees or disagrees with in the other premiss. Whatever therefore is the quality of this latter premiss must also be the quality of the conclusion.

(57.) The elements of a categorical syllogism have now been completely exhausted, and it is absolutely certain that if all the given rules are preserved inviolate, a formally incorrect conclusion can never be obtained.

All then that is necessary to ensure the legitimacy of a syllogism, is comprised in the five following rules :—

1. There cannot be more than one negative premiss.
2. If there is one negative premiss, the conclusion is negative; if there is no negative premiss, the conclusion is affirmative.
3. The middle term must be distributed in at least one of the premises.
4. If the predicate of the conclusion is distributed, the major term must be distributed in the major premise.
5. If the subject of the conclusion is distributed, the minor term must be distributed in the minor premiss.

The rules that have been given for the premises will only ensure a conclusion possible for the reason, and hence it will follow that the rules for the conclusion will in certain cases affect the premises also. For if the conclusion is negative, its predicate must be distributed; and therefore, by Rule 4, the major term must also be distributed in the major premiss.

(58.) Although the five given rules are quite sufficient in themselves, yet two others are derived from them, with which the student should be well acquainted, as they are of very easy application. They are—

1. No conclusion can be drawn from particular premises.
2. Only a particular conclusion can be drawn where one of the premises is particular.

As the middle term must always be distributed in one premiss at least, and as no term can be distributed in the conclusion that is not distributed in the premises, it follows that there must be at least one more distribution in the premises than in the conclusion. But there can be only one distribution in the predicates of the premises, as there can be only one negative premiss, and in that case there must be a distribution in the predicate of the conclusion, as that must also be nega-

tive. Hence it follows that the number of distributions in the subjects of the premises must exceed by at least unity, the number of distributions in the subject of the conclusion. If then both premises are particular, there will be no distributions in the subjects of the premises; and as the above condition will not be answered, there can be no conclusion. And if one premiss is particular, there will be only one distribution in the subjects of the premises, and therefore there can be none in the subject of the conclusion, *i. e.* the conclusion must be particular.

(59.) We shall now be able to extend our table for the premises only, and determine the moods in which a syllogism, perfect in all its parts, is possible. It must however be remembered, that as the table of sound premises paid no respect to the distinction of major and minor premiss, the order of the premises was there indifferent. But as the conclusion is here considered in its legitimate categorical forms, the distinction holds, and we must therefore examine the two permutations of each of those forms of premises.

Premises.	Conclusion.	Moods in which Paralogism is unavoidable.			Moods in which Syllogism is possible.
		Illicit Process of Minor.	Undistributed Middle.	Illicit Process of Major.	
A A with	A	—	—	—	A A A
	I	—	—	—	A A I
A I with	A	A I A	—	—	—
	I	—	—	—	A I I
I A with	A	I A A	or I A A	—	—
	I	—	—	—	I A I
A E with	E	—	—	—	A E E
	O	—	—	—	A E O
E A with	E	—	—	—	E A E
	O	—	—	—	E A O
A O with	E	A O E	or A O E	or A O E	—
	O	—	—	—	A O O
O A with	E	O A E	or O A E	or O A E	—
	O	—	—	—	O A O
E I with	E	E I E	—	—	—
	O	—	—	—	E I O
I E with	E	—	—	I E E	—
	O	—	—	I E O	—
I O with	E	I O E	or I O E	I O E	—
	O	—	—	I O O	—
O I with	E	O I E	O I E	or O I E	—
	O	—	O I O	or O I O	—

	SUBJECT.	PREDICATE.
A	Distributed.	Undistributed.
E	Distributed.	Distributed.
I	Undistributed.	Undistributed.
O	Undistributed.	Distributed.

The following example will shew how the above table should be studied.

Let us take the mood O A E. In this mood the predicate is distributed in the major premiss, and the subject in the minor premiss, and both subject and predicate in the conclusion. Hence it follows that either some term must be distributed in the conclusion which was not distributed in the premises, or else the middle term cannot be distributed in either premiss. We cannot therefore determine at once which form the fallacy will take, but may be quite certain that there must be either an illicit process of major or minor, or else an undistributed middle. Again, in the mood O I E, both subject and predicate are distributed in the conclusion, whereas no term is distributed in the minor premiss, and it therefore follows that there must be an illicit process of the minor. It is also evident that the middle term cannot be distributed in the minor premiss, and that if it is distributed in the major premiss, the major term must be undistributed, and consequently there must be a fallacy either of undistributed middle or illicit major.

(60.) It will be seen from the last column in the table, that there are eleven moods in which syllogism is possible, or in which the syllogistic

rules may be observed. But it does not follow that the rules of syllogism are necessarily observed in these eleven moods, as paralogism is possible in all but two of them ;* for in the premises of some of the moods we have but one distributed term, and in others two or more; and unless the position of the terms is such as to obey the laws for the distribution of the middle term, and prevention of illicit process, fallacy will still be the inevitable result.

The position of the terms will accordingly give rise to a further classification of categorical syllogisms. And as each premise admits of two permutations, in one of which the middle term is predicate, and in the other subject, there will be four combinations determined by its position, which are usually called the four syllogistic figures.

In the first figure, the middle term is the subject of the major premiss, and predicate of the minor.

In the second figure, the middle term is the predicate of both premises.

In the third figure, the middle term is the subject of both premises.

In the fourth figure, the middle term is the

* These two moods are E A O, and E I O, which are true in all the four figures.

predicate of the major, and subject of the minor premiss.

The following scheme will enable the reader to understand the distinction at a glance.

Let S represent the minor term (or subject of conclusion), M the middle term, and P the major term, (or predicate of conclusion).

	1st Fig.	2nd Fig.	3rd Fig.	4th Fig.
Major Premiss	M — P	P — M	M — P	P — M
Minor Premiss	S —M	S — M	M — S	M— S
Conclusion	S — P	S — P	S — P	S — P

In each of these figures several moods are sound, and others unsound. For instance, the mood A A A, which is sound in the first figure, in the second figure would have its middle undistributed in each premiss, while the mood A E E, which is sound in the second figure, would contain an illicit process of the major in the first figure. The accompanying table will shew what moods are sound, and what unsound, in each figure, and in the latter case, the peculiar form of the fallacy.

TABLE OF CATEGORICAL SYLLOGISM.

Name of Mood.	Form of Mood.	1st Figure.	2nd Figure.	3rd Figure.	4th Figure.

A A I	D — U D — U U — U	Sound	Undistributed Middle	Sound	Sound
A I I	D — U U — U U — U	Sound	Undistributed Middle	Sound	Undistributed Middle.
I A I	U — U D — U U — U	Undistributed Middle	Undistributed Middle	Sound	Sound
A E E	D — U D — D D — D	Illicit Major	Sound	Illicit Major	Sound
A E O	D — U D — D U — D	Illicit Major	Sound	Illicit Major	Sound
A O O	D — U U — D U — D	Illicit Major	Sound	Illicit Major	Undistributed Middle
E A E	D — D D — U D — D	Sound	Sound	Illicit Minor	Illicit Minor
E A O	D — D D — U U — D	Sound	Sound	Sound	Sound
E I O	U — D D — U U — D	Sound	Sound	Sound	Sound
O A O	U — D D — U U — D	Undistributed Middle.	Illicit Major	Sound	Illicit Major

In the first column of this table, the name of the mood is given. In the second, its form with regard to the distribution of its terms, where D signifies distributed, and U signifies undistributed. In the other four columns, which are headed by the forms of the four figures, the nature of each mood in each figure is expressed by the word 'sound,' if the reasoning is unobjectionable, and if not so, by the name of its particular fallacy.

By comparing the form of one of the moods with the general form for any one of the figures given in the upper line of the table, we shall see if any D in the one corresponds in position with an M in the other, in which case the middle will be distributed. We must also observe if either S and P in the conclusion correspond with a D in the form of the mood, and if so, they must correspond respectively with a D in the premises, or else there will be an illicit process. With this explanation there will be no difficulty in understanding the manner in which the table is formed. For instance, let us take the mood A A A. We find in the form of the mood that the subject in each premiss is distributed, and upon turning to the form of the first figure, we find that the subject of the major premiss is the middle term, and are therefore justified in concluding

that the mood A A A in the first figure has its middle distributed. Again, we find that the only term in the conclusion corresponding to a D, is S, which also corresponds to a D in the premises. We are therefore certain that no term is distributed in the conclusion that is not also distributed in the premises, or, in other words, that there is no illicit process; and as the middle is distributed, it follows that the syllogism A A A in the first figure is sound.

If however we compare the form of the mood A A A, with the form of the third figure, we find that S the subject of the conclusion corresponds to D, and is therefore distributed; but that S the predicate of the minor premiss corresponds to U, and is therefore undistributed: whence it follows that A A A in the third figure has an illicit process of the minor.

(61.) Several laws may be obtained for each figure, by an examination of their peculiar forms.

In the first figure, the minor premiss must be affirmative: for if it were negative, the major premiss must be affirmative, and therefore have its predicate, which is the major term, undistributed. But the conclusion must be negative, and therefore its predicate would be distributed, which would accordingly give rise to an illicit process of the major.

As the minor premiss must be affirmative, the middle term, which is its predicate, must be undistributed in that premiss, and therefore distributed in the other premiss, in which it holds the place of subject. Hence it follows that the major premiss must always be universal in the first figure.

In the second figure, the middle term is the predicate in each premiss; and as it must be distributed in one of them, one premiss must be negative, and therefore the conclusion also. In the third figure the minor premiss must always be affirmative for the same reasons as in the first figure; and therefore its predicate (which is the minor term), being undistributed, the conclusion must be particular, for were it universal, there would be an illicit process of the minor. There are several other rules which may be derived from the primary laws, but as all of them may be more simply evolved by means of algebraical symbols, we shall postpone their consideration for the present.

Transformation of the figures of Syllogism.

(62.) It has been already observed, that Aristotle's dictum (or the first figure) is the form in which our reasoning appears the most natural, and is most easily comprehended. This is the reason why the other three

figures have been considered as unnatural deviations from it, and that laws have been laid down for the reduction of all syllogisms to the original form of the first. But as this peculiarity of the dictum is based on the laws of an understanding-conception, and as Formal Logic can pay no attention to a distinction which originates in grounds that lie out of its field, it will be more correct to consider the laws for transforming a syllogism from any one figure into another, especially as they will include the laws for reduction (or transformation to the first) as a particular case. As the distinction of figure depends entirely on the position of the terms, conversion, by which alone this can be altered, is the only method of transformation. But this operation is not always possible, as in many of the moods the propositions are not of a convertible form: *e. g.* it is impossible to transform the mood A E O from the second figure into the first; for the major premiss is not simply convertible, and limited conversion would give the mood I E O, which contains an illicit process of the major. The following table can therefore only give those conditions which must be answered by any syllogism in each figure for its transformation into any other; but in order to know if a syllogism is capable of answering

these conditions, it will be necessary to examine its particular mood.

TRANSFORMATION TABLE.

Figure to be transformed.	Propositions to be converted for transformation into the			
	First figure	Second figure	Third figure	Fourth figure
First		Major	Minor	Conclusion * or Major & Minor
Second	Major		Major and Minor	Minor or Major & Conclusion
Third	Minor	Major and Minor		Major
Fourth	Conclusion or Major & Minor	Minor	Major	

(63.) It appears from the table at Art. 60, that there are six moods in each figure which answer all the required conditions for a sound categorical syllogism. Five of these have been very generally rejected by logicians, on the grounds of their having particular conclusions, although universal are warranted by the premises.† But this regard to a more prac-

* It is hardly necessary to observe, that whenever the conclusion is converted, the major and minor terms, which are respectively its predicate and subject, must be interchanged, and therefore the premises that contain them.

† These five are the moods A A I in the first figure, E A O in the first and second, and A E O in the second and fourth.

tical utility is always very unphilosophical in an *à priori* science, and especially if it be at all destructive of the symmetry of our results. The mathematician will readily acknowledge his obligations to symmetry for the light it throws upon truths already known, as well as for its efficiency as an organum for the discovery of new ones: and the same regard should be paid to it in every pure science, but more particularly in one which is intended to increase the accuracy and rigid strictness of our thought. In the present case there are six syllogisms in each of the four figures, and this reduction would have only nineteen, four in the first and second, six in the third, and five in the fourth. Some of the old schoolmen carried their veneration for Aristotle so high, as to reject the fourth or Galenic * figure entirely, and thus reduced the whole number to fourteen. But this reduction is nearly as unphilosophical as the other, for the only rational ground upon which it can rest will apply to the second and third figures also, though not perhaps to the same extent. We shall therefore submit to the reader the whole

* The fourth figure was first recognised by Galen, the great medical philosopher, who flourished in the second century.

twenty-four syllogisms, collected under their respective figures.*

Hypothetical Syllogism.

(64.) One premiss of a hypothetical syllogism is a hypothetical proposition; the other premiss is a categorical proposition, and either asserts

* There is a barbarous practice of naming the various forms of a categorical syllogism by certain words which constitute mnemonic hexameters. A subject which should always be treated in a rational point of view (*i. e.* as appertaining to the reason), is in this manner degraded to a mere historical record of the deductions of others, and draws upon the memory alone. Having entered my protest against these lines, I still think it proper to subjoin them, in order that the student may understand the allusion when he hears such phrases as 'a syllogism in barbara,' &c. The vowels contained in the words of these lines give the names of the moods, and the consonants refer to their other peculiarities,—such, for instance, as the methods of reducing them to the first figure. The two first lines give the nature of the four categorical propositions.

Asserit A, negat E, verum generaliter ambæ.
Asserit I, negat O, sed particulariter ambæ.

Barbara, Celarent, Darii, Ferioque, prioris
Cesare, Camestres, Festino, Baroko, secundæ.
Tertia, Darapti, Disamis, Datisi, Felapton,
Bokardo, Ferison habet: Quarta insuper addit

Quinque Subalterni, totidem Generalibus orti,
Nomen habent nullum, nec, si bene collegis, usum.

the antecedent, or denies the consequent. In the former case, which is called the modus ponens, the conclusion infers the truth of the consequent; in the latter case, which is called the modus tollens, the conclusion infers the falsity of the antecedent. The general forms of these two cases are, 'If A is, B is; but A is; therefore B is;' and 'If A is, B is; but B is not; therefore A is not.' Example, 'If what we learn from the bible is true, we ought not to do evil that good may come; but what we learn from the bible is true; therefore we ought not to do evil that good may come.'

These are the only two forms which a hypothetical syllogism can assume. For no variation can enter on the side of the hypothetical (which is usually styled the major) premiss, as there is but one form of such propositions; neither can there be any other form for the categorical (which is usually styled the minor) premiss than those already mentioned, for nothing can be inferred by denying the antecedent or asserting the consequent. As, moreover, the latter premiss only concerns the truth or falsity of the members of the hypothetical, all variations in its form, when considered merely as a categorical proposition, must affect its matter and not its form when considered as the minor premiss.

Disjunctive Syllogism.

(65.) In this syllogism, we commence with a disjunctive judgment, and proceed either by asserting the truth of one member of the division, and thence inferring the falsity of all the rest, which is called the 'modus ponens,' or else by asserting the falsity of all the members but one, and hence inferring the truth of that one, which latter method is called the 'modus tollens.' The general form of these two cases will be, 'Either A is, or B is, or C is; but A is; therefore neither B is, nor C is.' And 'Either A is, or B is, or C is; but neither B is, nor C is; therefore A is.' We may take as an example 'Either the Pope is infallible, or there is at least one great error in the Romish church; but the Pope is not infallible; therefore there is at least one great error in the Romish church.'

These may be shewn to be the only forms of a disjunctive syllogism by reasoning very similar to that employed in the case of the hypothetical.

Dilemma, &c.

(66.) Besides the three simple forms of syllogism already mentioned, there are several others, of which perhaps the Dilemma is the most important. This is an hypothetical syllogism, whose consequent is divided into members by

a disjunctive judgment. Thus, 'if A is B, either C is D, or E is F' is the general form of the major premiss of a dilemma; and as it is hardly ever used except in the modus tollens, the minor premiss and conclusion will be 'But neither C is D, nor E is F, therefore A is not B.'

(67.) The following are examples of combinations of premises which differ from those already given in respect of the moments of relation. Thus, two hypotheticals will give—

'If A is B, C is D; but if C is D, E is F; therefore if A is B, E is F.'

Or, 'If A is B, C is D; but if E is F, C is not D; therefore if E is F, A is not B.'

'If A is B, C is D; and if A is not B, E is F; therefore either C is D, or E is F.'

In the same manner two disjunctives will give—

'A is either B or C; but B is either D or E; therefore A is either C or D or E.'

Or a categorical and disjunctive—

'A is either B or C; D is A; therefore D is either B or C.'

Enthymeme.

(68.) The Enthymeme is a syllogism abridged by the suppression of one of its premises, which is nevertheless understood, as the argument

would not be valid without it. For, as the conclusion and either premiss are sufficient to indicate what the other premiss must be, we rarely express both premises in practice, but generally leave one of them to the hearer or reader to supply. The following is an example of a categorical enthymeme:

'The science of Logic is very useful, as it enables us to detect the formal fallacies in the arguments of our adversaries'. Here the major premiss is suppressed. The completed syllogism will stand thus—

'Whatever enables us to detect the formal fallacies in the arguments of our adversaries is very useful; the science of Logic enables us, &c.; therefore the science of Logic is very useful.' Had the minor premiss been suppressed, the enthymeme would have been—

'The science of Logic is very useful, for any thing is useful that enables us to detect the formal fallacies in the arguments of our adversaries.'

The following is an example of an hypothetical enthymeme:—

'It will certainly rain, for the sky looks very black.'

In this case the major premiss is suppressed. The syllogism when completed would stand thus—

'If the sky looks black, it will certainly rain.

'The sky does look black.

'Therefore it will certainly rain.'

Had the minor premiss been suppressed, the enthymeme would have been of the following form :—

'It will certainly rain, for it always rains if the sky looks black.'

The following examples are two disjunctive enthymemes in which the major and minor premises of the same syllogism are respectively suppressed :—

'He must be in York, for he is not in London.'

The suppressed premiss is, 'he must be either in London or York.'

If the minor premiss is suppressed the enthymeme will become—

'He must be in York, for he must be either in London or York.'

Sorites.

(69.) In a Sorites the conclusion of a syllogism is not expressed, but made the suppressed premiss of an enthymeme whose conclusion may be made the suppressed premiss of another, and similarly for any number of enthymemes. Thus, 'B is A, C is B, D is C, E is D;

therefore E is A' is a categorical Sorites. Again, 'If A is, B is; if B is, C is; if C is, D is; but D is not; therefore A is not,' is a specimen of an hypothetical Sorites.

SECTION V.

THE DEDUCTIO AD ABSURDUM, OR INDIRECT PROOF.

(70.) This name is given to a circuitous method of proving one proposition from two or more others, by means of at least three syllogisms. As, however, the principle of the proof is quite independent of the number of given propositions, our present object will be fully answered by an investigation of that case, in which they are limited to two. And, moreover, as the forms of syllogism contain all the principles or functions of the reason, by which one proposition can be thought as necessarily connected with several others, it follows, that any conclusion at which we can arrive by the *deductio ad absurdum*, might also have been obtained by the direct application of one of the regular syllogistic forms of ratiocination. We may therefore consider the given propositions, and the one to be deduced from them, as the premises and conclusion of a syllogism, and proceed to shew how this conclu-

sion may be obtained by a different chain of reasoning.

The method, then, consists first, in assuming the falsity of the conclusion and truth of one premiss, and deducing from these propositions as premises, the falsity of the other premiss, as a conclusion; secondly, in taking this conclusion as the consequent, and the premises of the last syllogism as the antecedent in a hypothetical syllogism, and inferring the falsity of the antecedent by the modus tollens; thirdly, in dividing this falsity in a disjunctive syllogism into its three members, viz. the falsity of each proposition separately, or of both together, and inferring the falsity of that member of the division which is the contradictory of the original conclusion by the modus ponens. But the reader will understand this method more easily by examining the following general form:

Let A and B represent the premises, and C the conclusion of any syllogism. In order to prove C by the indirect method, we commence with assuming that C is not true. The three syllogisms may be then stated as follows:

First syllogism: 'A is; C is not; therefore B is not.

Second syllogism: 'If A is, and C is not,

it follows that B is not; but B is; therefore it is false that "A is and C is not.'"

Third syllogism: 'Either both propositions "A is" and "C is not" are false, or else one of them is false; but that "A is" is not false; therefore that "C is not" is false, (*i. e.* C is').

The hypothetical syllogism is rarely if ever expressed in practice; the disjunctive, perhaps, never. But, in an analysis of the indirect proof, it would be just as unreasonable to neglect the consideration of these syllogisms on the ground of their being rarely expressed, as it would be in an analysis of syllogism generally to neglect the consideration of one of the premises on the ground of our usually reasoning in enthymemes.

Although the *deductio ad absurdum* requires premises from which the conclusion might have been deduced by the direct method, yet is it frequently very useful when these premises are of such a nature as not to admit of a very convenient syllogistic form. It is on this account not unfrequently used in the propositions of geometry, though Euclid has occasionally introduced it when the direct proof would have been equally simple. An instance of this will be found in the fourth proposition of the third book, in which it is required to prove that 'If in a

circle two straight lines cut one another which do not both pass through the centre, they do not bisect each the other.' The indirect proof assumes that they bisect each other, and then shews that they must both be perpendicular to a line joining the centre and the point of their intersection, which is absurd; therefore, &c. Whereas the direct proof states that all chords which are bisected by the line drawn from the centre to the point of intersection must be perpendicular to that line; but both of these chords are not perpendicular to that line; therefore both of these chords are not bisected by the line drawn from the centre to the point of their intersection, which cannot therefore be the point of their bisection.* But every proposition which admits the *deductio ad absurdum*, will also admit of a direct proof from the same data, though in a great many cases the direct proof would be exceedingly clumsy, and not nearly as simple as the indirect. There is a very striking instance of this in the usual proof of the falsity of a hypothetical or disjunctive proposition from two categorical premises. The reasoning is rather abstruse, but it bears too completely upon the present subject to be entirely

* This syllogism is the mood A O O in the second figure.

overlooked, and is therefore subjoined in a note.*

* Hypothetical and disjunctive differ from categorical propositions in not possessing the quality of negation objectively. For if the cognition upon which any one of them is grounded (*i. e.* the dependence of one particular cognition upon another, or its division into members) does not hold in nature, there is no other hypothetical or disjunctive proposition which can simply assert this want of objectivity. This remark has been made already (Art. 42—44) where it was observed that a proposition which simply denies the dependence of a particular cognition on another, or the completeness of the division of a cognition, in neither case gives any new dependence of cognitions, or any new exhausting division, and consequently cannot be either hypothetical or disjunctive, but must be simply categorical. If then two categorical propositions are granted as premises, from which we are to deduce as conclusion the falsity of an hypothetical or disjunctive proposition, these two premises must be referred to the thinking subject as the only middle term by which they can be united in an act of reason, for all common objective grounds are denied them by the very nature of the case. This necessity for a subjective reference renders the reasoning so much more abstruse, that the mind naturally chooses the other method of *deductio ad absurdum*, which, from its objective nature, is much easier of comprehension. In this method we assume the falsity of our desired conclusion (which conclusion is, in this case, the contradictory of an hypothetical or disjunctive proposition) and therefore assume the truth of the hypothetical or disjunctive, and conjoining it with one of our given premises, deduce the falsity of our other premiss; in this manner we entirely avoid the necessity of any reference to the thinking subject. We will exemplify this reasoning as follows:—

Let the given premises be, 'A is; B is not,' from which we are to deduce the falsity of the hypothetical proposition,

'If A is, B is.'

If I would deduce this falsity (which being the contradictory of a hypothetical must be contained in a categorical proposition) by the direct method, I must refer the two premises to the thinking subject 'I' in some such manner as the following:—

(71.) The *deductio ad absurdum* supplies the principle upon which may be founded a rather pretty and symmetrical arrangement of the twenty-four categorical syllogisms. It also suggests a method of proving the necessary equality of the moods true in the first three figures without the aid of mathematical analysis, and of shewing the reason why the number of negative syllogisms is exactly double the number of the affirmative. And although we do not propose to derive any particular practical advantage from its consideration, yet anything that tends to give additional order and theoretical completeness must always have a sufficient value in a pure science to warrant its insertion.

As in every categorical syllogism we may

'Whatever is in my present consciousness is conjoined in it with my assent to the conception of B not being.

'My assent to the conception of A being is in my present consciousness.

'Therefore my assent to the conception of A being is conjoined in my present consciousness with my assent to the conception of B being.'

This conclusion is the categorical statement of the falsity of the hypothetical which can only be shewn directly by this or some other equally clumsy method. The indirect proof however, is simple enough, and may be stated thus:

Let us assume that the hypothetical is true, or that 'if A is, B is; but A is; therefore B is; but B is not, therefore,' &c.

As we have already stated, the simplicity of the proof in this case arises from every premiss contained in it having an objective reference, which the contradictory of a hypothetical has not.

either employ the major premiss and contradictory of the conclusion to disprove the minor premiss, or the minor premiss and contradictory of the conclusion to disprove the major premiss, it follows that there must be two distinct syllogisms, with either of which we may commence an indirect proof. The forms which they respectively assume will readily appear from the following table :—

	Major Premiss and Contradictory of Conclusion being Premises.	Minor Premiss and Contradictory of Conclusion being Premises.
First Figure. $\left\{\begin{matrix}M-P\\S-M\\S-P\end{matrix}\right\}$ becomes	Second Figure. $\left\{\begin{matrix}M-P\\S-P\\S-M\end{matrix}\right\}$	Third Figure. $\left\{\begin{matrix}S-P\\S-M\\M-P\end{matrix}\right\}$
Second Figure. $\left\{\begin{matrix}P-M\\S-M\\S-P\end{matrix}\right\}$ becomes	First Figure. $\left\{\begin{matrix}P-M\\S-P\\S-M\end{matrix}\right\}$	Third Figure. $\left\{\begin{matrix}S-M\\S-P\\P-M\end{matrix}\right\}$
Third Figure. $\left\{\begin{matrix}M-P\\M-S\\S-P\end{matrix}\right\}$ becomes	Second Figure. $\left\{\begin{matrix}S-P\\M-P\\M-S\end{matrix}\right\}$	First Figure. $\left\{\begin{matrix}S-P\\M-S\\M-P\end{matrix}\right\}$
Fourth Figure. $\left\{\begin{matrix}P-M\\M-S\\S-P\end{matrix}\right\}$ becomes	Fourth Figure. $\left\{\begin{matrix}S-P\\P-M\\M-S\end{matrix}\right\}$	Fourth Figure. $\left\{\begin{matrix}M-S\\S-P\\P-M\end{matrix}\right\}$

From this table it is immediately evident that for every sound mood in the first figure,

there must also be a sound mood in the second and third; that for every sound mood in the second figure, there must also be one in the first and third; and for every sound mood in the third figure, one in the first and second. Hence it follows, that the number of moods that are sound in each of the first three figures must be the same. But the form of the fourth figure is such, that it only admits of an indirect proof by syllogisms in the same figure; and the equality, therefore, of the number of its moods to that of the moods in the other three figures, is not susceptible of this method of proof.

This table will supply the grounds of a division of categorical syllogisms into eight systems, containing three each. Six of these systems have one mood in each of the first three figures. The other two are contained entirely in the fourth. The systems are as follows:—

Figure	1	2	3	4	5	6
First	A A A	A A I	A I I	E A E	E A O	E I O
Second	A O O	A E O	A E E	E I O	E A O	E A E
Third	O A O	E A O	E I O	I A I	A A I	A I I

Fourth Figure.

7	8
A A I	I A I
A E O	A E E
E A O	E I O

Each system must contain one affirmative and two negative syllogisms. For the contradictory of the conclusion of every affirmative syllogism must constitute one of the premises in its two complementary syllogisms, or those contained in the same system with itself; and as this contradictory must be a negative proposition, the two syllogisms that contain it must be negative also. Hence, every affirmative syllogism must have two complementary negative syllogisms. And as the affirmative contradictory of the conclusion of a negative syllogism may be combined with either its negative or its affirmative premiss, its two complementary syllogisms must themselves also be the one negative, and the other affirmative. As, then, every system contains one affirmative, and two negative syllogisms, it is evident that the whole number of negative must double the number of affirmative syllogisms.

SECTION VI.

SYMBOLICAL EXPRESSION FOR THE LAWS OF CATEGORICAL SYLLOGISM.

(72.) The conditioning laws of categorical syllogism admit of a very simple analytical expression from which all its properties may be readily obtained. But the more especial object in treating this subject mathematically, is the exhibition of that symmetry, from which, the equality of the number of moods that are true in the first three figures, may be derived *à priori* to all consideration of the moods themselves. Before, however, we proceed to make any assumptions, it is necessary to remind the reader, that the usual arithmetical interpretation of the symbols employed has no natural connection with the subject under consideration, but can merely be useful as an index to the laws of their combination. If, for instance, any sets of symbols be juxtaposed, and equated to zero, the equation will indicate that at least one of these factors may itself be singly equated to zero; and, in that case, all its con-

stituent symbols must receive whatever interpretations may arise from the transposition of terms, or any other operations, that are formally analogous to those of arithmetical algebra, and have been admitted in our particular application of the science. In the present case the conception of homogeneity is not introduced, and it will therefore follow, that, if several symbols are equated to several others, each of those on one side of the equation must be considered as equated to one on the other, but no division of a symbol into parts will be considered admissible.

The laws of categorical syllogism have been already once stated, but are nevertheless repeated here, as a trifling alteration in the manner of expressing those respecting quality will be necessary for their reduction to a mathematical form. As the latter will be represented in a single equation, it will be more convenient to throw them into one rule, which may be stated as follows:—

(1.) At least one of the premises must have an affirmative copula, and the quality of the conclusion will be the same as that of the remaining premiss.

As this law respects the quality of the copulas, which will always determine the quantity of the predicates, it may be written thus:

1. The predicate of at least one of the premises is undistributed, and the predicate of the conclusion will be of the same quantity as the predicate of the other premiss.

The other three laws are—

2. The middle term must be distributed in at least one of the premises.

3. The major term must not be distributed in the conclusion, unless it has been distributed in the major premiss.

4. The minor term must not be distributed in the conclusion, unless it has been distributed in the minor premiss.

Let u represent an undistributed term.

Let d represent a distributed term.

Also, let p_1, p_2, p_3, and s_1, s_2, s_3, represent the predicates and subjects respectively of the three propositions as expressed below.

	SUBJECTS.	PREDICATES.
Major premiss	s_1	p_1
Minor premiss	s_2	p_2
Conclusion	s_3	p_3

where each of these symbols must $= d$ or u.

Now, observing from rule (1), that at least one of the predicates of the premiss (i. e. p_1, p_2) must be undistributed or $= u$, we may express the other predicate as $= p_1 + p_2 - u$.

But by the latter clause of law (1) we also find that whatever is the quantity of that pre-

dicate, must also be that of the predicate of the conclusion, and we shall therefore have

$$p_3 = p_1 + p_2 - u, \ldots \text{law (1)};$$

and this equation will be a correct expression for law (1).

Now from law (2) we find that the middle term must be distributed (i.e.$=d$), in at least one premiss, and as s_1 and p_2 are the middle term in the first figure, one or both of the following equations must be true in that figure,

$$(s_1 - d) = 0$$
$$(p_2 - d) = 0;$$

and we shall therefore have

$$(s_1 - d)(p_2 - d) = 0 \ldots \text{law (2)}$$

as an equation expressing the second law for the first figure; and as the same reasoning will apply to all the four, we shall have

$$\left.\begin{array}{l} \text{Fig. (1)} \ldots (s_1 - d)(p_2 - d) = 0 \\ \text{Fig. (2)} \ldots (p_1 - d)(p_2 - d) = 0 \\ \text{Fig. (3)} \ldots (s_1 - d)(s_2 - d) = 0 \\ \text{Fig. (4)} \ldots (p_1 - d)(s_2 - d) = 0 \end{array}\right\} \ldots \text{law (2).}$$

Again, from law (3) we know that either the predicate of the conclusion, i. e. p_3, must be undistributed or $= u$, or else the major term which is either s_1 or p_1 according to the figure must be distributed or $= d$; and by reasoning similar to the preceding we shall have

$$\left.\begin{array}{l}\text{Fig. (1)} \ldots . (p_1 - d)(p_3 - u) = 0 \\ \text{Fig. (2)} \ldots . (s_1 - d)(p_3 - u) = 0 \\ \text{Fig. (3)} \ldots . (p_1 - d)(p_3 - u) = 0 \\ \text{Fig. (4)} \ldots . (s_1 - d)(p_3 - u) = 0\end{array}\right\} \ldots \text{law (3).}$$

In precisely the same manner we may obtain the following expressions for law (4).

$$\left.\begin{array}{l}\text{Fig. (1)} \ldots . (s_2 - d)(s_3 - u) = 0 \\ \text{Fig. (2)} \ldots . (s_2 - d)(s_3 - u) = 0 \\ \text{Fig. (3)} \ldots . (p_2 - d)(s_3 - u) = 0 \\ \text{Fig. (4)} \ldots . (p_2 - d)(s_3 - u) = 0\end{array}\right\} \ldots \text{law (4).}$$

We shall now assume the symbols p'_3 and s'_3 of such a nature that

$$p'_3 + p_3 = d + u \ldots\ldots\ldots (5).$$
$$\text{and} \quad s'_3 + s_3 = d + u \ldots\ldots\ldots (6).$$

And as it has been already stated that homogeneity is not introduced in the conception of our symbols, it will follow from these equations that p'_3 and s'_3 are each $= d$ or u. They will also be respectively complementary to p_3 and s_3 in such a manner that when one $= u$, the other $= d$, and *vice versa;* and they will therefore be of precisely the same nature as the other six symbols, p_1, p_2, &c.

From (5) and (6) we obtain for the values of p_3, s_3 respectively

$$p_3 = d + u - p'_3$$
$$s_3 = d + u - s'_3.$$

And substituting these values of p_3 and s_3 in the equations (1), (3), and (4), we shall get

the following sets of equations for the four figures of categorical syllogism.

* $p_1 + p_2 + p'_3 = d + 2u \ldots$ (1)
$(s_1 - d)(p_2 - d) = 0 \ldots$ (2)
$(p_1 - d)(p'_3 - d) = 0 \ldots$ (3)
$(s_2 - d)(s'_3 - d) = 0 \ldots$ (4)
} First figure.

$p_1 + p_2 + p'_3 = d + 2u \ldots$ (1)
$(p_1 - d)(p_2 - d) = 0 \ldots$ (2)
$(s_1 - d)(p'_3 - d) = 0 \ldots$ (3)
$(s_2 - d)(s'_3 - d) = 0 \ldots$ (4)
} Second Figure

$p_1 + p_2 + p'_3 = d + 2u \ldots$ (1)
$(s_1 - d)(s_2 - d) = 0 \ldots$ (2)
$(p_1 - d)(p'_3 - d) = 0 \ldots$ (3)
$(p_2 - d)(s'_3 - d) = 0 \ldots$ (4)
} Third Figure.

$p_1 + p_2 + p'_3 = d + 2u \ldots$ (1)
$(p_1 - d)(s_2 - d) = 0 \ldots$ (2)
$(s_1 - d)(p'_3 - d) = 0 \ldots$ (3)
$(p_2 - d)(s'_3 - d) = 0 \ldots$ (4)
} FourthFigure

(73). If we examine the equations to the first three figures, we shall find each set per-

* The following is the most general symbolical expression for the syllogistic laws.

Let x and y represent the middle term in the major and minor premises respectively, and m and n the major and minor terms. The equations will then be equally applicable to all the four figures, and will assume the following forms:

$$p_1 + p_2 + p'_3 = d + 2u \ldots (1).$$
$$(x - d)(y - d) = 0 \ldots (2).$$
$$(m - d)(p'_3 - d) = 0 \ldots (3).$$
$$(n - d)(s'_3 - d) = 0 \ldots (4).$$

where $x + m = p_1 + s_1 \ldots (5).$

and $y + n = p_2 + s_2 \ldots (6).$

fectly symmetrical with respect to the other two. For in equation (1), which is common to all the three figures, the symbols p_1, p_2, p_3 are perfectly symmetrically involved, and the only assumptions that have been made respecting s_1, s_2, s_3 are that each of them must either $=$ d or u. Hence any interchange among the three symbols s_1, s_2, s'_3 or the three p_1, p_2, p'_3 will not in the least affect the form of the equations. But if we interchange p_2 and p_3' in the equations to the first figure, we shall obtain the equations to the second; and if we interchange s_1 and s'_3 in the first figure, we shall obtain the equation to the third; or lastly, if we interchange p_2 and p'_3, also s_1 and s_3', in the equations to the third figure, we shall obtain those to the second; and of course the same interchanges will reproduce the first from the second, the first from the third, &c.: hence it follows that the sets of equations to the first three figures are perfectly symmetrical with regard to each other.*

If however it were required to obtain the

* Although the sets of equations to the first three figures are perfectly symmetrical with respect to each other, yet does it by no means follow that the corresponding equations represent the same laws. The equation that contains the law against illicit major in the first figure, corresponds to the similar equation in the third; but in the second figure it corresponds to the equation containing the law for the distribution of the middle term; and similarly of the others.

equations to the fourth figure from those to either of the other three, it would be necessary to interchange one or more of the three symbols s_1, s_2, s_3' with one or more of the symbols p_1, p_2, p_3'; and this cannot be admitted, as the three latter symbols are all involved in equation (1), whereas the three former are neither involved in that or any other corresponding equation; and hence it follows that the equations to the fourth figure are not symmetrical with those to the other three.

(74.) As the symbols are symmetrically involved in the equations to the first three figures, we can know *à priori* to all other considerations that there must be the same number of solutions, and therefore the same number of true moods for all of them. But as the equations to the fourth figure do not involve the symbols symmetrically with the equations to the other three, we cannot say at once that the number of their solutions must be the same as in those to the other figures, but can only shew that it is so by determining the number of solutions in each case. For this purpose it will be sufficient to investigate separately the number of solutions for the first and fourth figures.

We will commence by examining the first figure. It is evident from equation (1), that

one of the symbols p_1, p_2, p_3' must $= d$, and the other two each $= u$; and from equation (3) that either p_1 or p_3' must $= d$. Hence there will be two solutions for equation (3) (accordingly as p_1 or $p_3 = d$), which, will correspond to two solutions for equation (1).

But as equation (3) requires that either p_1 or p'_3 should $= d$, it follows from equation (1) that p_2 must always $= u$, and therefore from equation (2) that $s_1 = d_1$, or otherwise neither factor in equation (2) would vanish. Hence there is but one solution for equation (2), and only two solutions for the equations (1) and (3), as the latter are mutually dependent on each other. Equation (4) will have three solutions, accordingly as both together or either separately of the symbols s_2 and $s_3' = d$. And as the solutions of equation (4) are quite independent of the symbols involved in the equations (1), (2), (3), it follows that any one of the three solutions of the former may be combined with either of the two solutions of the other three equations, and thus produce six sets of solutions which will correspond to the six moods that are sound in the first figure.*

* Great care must be taken, in the interpretation of these equations into their corresponding moods, not to confound p'_3 with p_3, or s'_3 with s_3. The values of p'_3, and s'_3 are first determined

In the fourth figure we shall have three solutions for equation (1), accordingly as either of the three symbols p_1, p_2, or p'_3 may $= d$. Of the other three equations (2), (3), and (4), that which contains the particular symbol of the three p_1, p_2, p'_3 which $= d$, will admit of two solutions; but the two equations which respectively contain those two of the three symbols p_1, p_2, p'_3 that are $= u$, will admit but of one solution. Hence, each of the three solutions of equation (1) may be combined with the two solutions of one of the other three equations, and thus produce six combinations which will respectively answer to the six moods of the fourth figure.

Although we have only been able to prove that the number of moods in the fourth figure is equal to that in the other three, by the numerical tentative method already given, yet can we at least shew that no other method is possible. For it is evident that the only method by which such an equality can be shewn independently of numbers, is that of form, which has been already employed in be-

by the four equations to the figure under consideration, and from them the values of p_3 and s_3 are deduced by means of the equations

$$p_3 + p'_3 = d + u,$$
$$s_3 + s'_3 = d + u,$$

and will indicate the peculiar categorical form of the conclusion.

hoof of the first three figures. But the equations to those three figures completely determine two of their six symbols (s_1 and p_2 in the first; s_1 and p_3' in the second; and p_2 and s'_3 in the third), whereas the equations to the fourth do not determine a single one, but admit variations in all. Hence it follows that no artifice can bring the equations to the fourth figure under the same form as the equations to the other three, and consequently that all formal proof of the equality of the number of the solutions is absolutely impossible.

(75.) Among other advantages in the symbolical expression of the laws of categorical syllogism, we may mention the facility with which the derived secondary laws may be obtained, and the peculiar fallacies exposed which their violation entails. For instance, we know from equation (1), that one alone of the symbols p_1, p_2, p'_3 can $= d$; and moreover from equation (3) in the first figure, that either p_1 or p_3' must $= d$. We may therefore conclude that $p_2 = u$, that is to say, the predicate of the minor premiss in the first figure is undistributed, and the quality of its copula affirmative. But if $p_2 = u$, it will follow from equation (2) in the first figure that $s_1 = d$, or in other words that the subject of the major

premiss is distributed, and that premiss an universal proposition. Should either of these secondary laws be violated, the conditions of one of the equations (2) or (3) cannot be fulfilled, and there must either be a fallacy of undistributed middle, or illicit process of the major. In the same manner it may be proved, that in the second figure $s_1 = d$, and $p'_3 = u$, (or $p_3 = d$,) in other words, that the major premiss must be universal, and the conclusion negative. But these examples are sufficient to enable the reader to derive the other laws for himself.

Truth of Premises.

(76.) To assert that 'if the premises are true, the conclusion that is deduced from them must be true likewise,' is a mere tautology; for the very definition of a conclusion is 'that proposition, the truth of which follows necessarily from the truth of the premises.' But the converse of this proposition is by no means true, for it does not follow that if the conclusion is true, the premises from which it is deduced must be true also. A more satisfactory explanation of this subject will be given in a future section: the following, however, is

an unobjectionable proof by the method of the *deductio ad absurdum.**

Let us assume that if the conclusion is true, the premises must be true also; it will follow that if the premises are not true, the conclusion will not be true either. Let any sound mood in any figure be represented by the general symbols $x\,y\,z$, and let x', y', z', represent the formal contradictories of the propositions x, y, z respectively. Let one or both of the premises x and y be false; it follows from our present hypothesis, that z must be false also. If then, for example, x is false, and its falsity is sufficient to ensure the falsity of z, and if we substitute for x a proposition which merely states that falsity, we may also substitute for z a proposition which merely states its falsity, and thus change the form without affecting the soundness of the reasoning. But the contradictories of x and z respectively state the falsity of those propositions, and consequently a syllogism of the form $x'\,y\,z'$ must represent

* This proof will only strictly apply to categorical syllogisms. It may, however, be extended to the hypothetical and disjunctive by converting their form into the matter of a categorical. Thus the hypothetical, 'if A is, B is; A is, therefore B is,' may have its form put into the matter of a categorical in the usual way, commencing with 'all the cases of A being,' &c., and as this categorical syllogism may have false premises and true conclusion, it is evident the hypothetical may also.

an unobjectionable mood in the same figure as that of $x\ y\ z$. And as we might have assumed that y was false instead of x, or that both were false together, we shall have the three moods $x'\ y\ z'$, $x\ y'\ z'$, and $x'\ y'\ z'$ all sound in the same figure as that of $x\ y\ z$.

But contradictories differ from each other in the quantity both of their predicates and subjects. If, then, we recur to the symbolical expression of the syllogistic laws (Art. 73), we must find that for every solution of the equations there given, three corresponding solutions may be obtained by exactly reversing the values of s'_3 and p'_3 together with the values of one or both pairs of symbols s_1, p_1 and s_2, p_2 in such a manner that those which $= u$ should $= d$, and *vice versâ*. But it was shewn in Art. 74, that in the first figure the values of s_1 and p_2 are determined by the equations (1), (2), and (3), and consequently neither of the pairs of symbols s_1, p_1 or s_2, p_2 can have their values reversed in that figure. In the second figure we find the symbol p'_3 determined by the equations (1) and (2), and in the third figure the symbol s'_3 determined by the equations (1), (3), and (4), and consequently the changes of values cannot take place in these two figures any more than in the first. Again, it appears from the equations to the fourth figure, that

when s_1 can change its value, p_1 is determined, and when s_2 can change its value, p_2 is determined, and consequently in neither case can one of the pairs s_1, p_1 or s_2, p_2 both change their values simultaneously. Hence it follows that the conclusions at which we have arrived are all false, and consequently that the hypothesis which we assumed must be false also; and that true conclusions may be deduced from false premises in every figure of categorical syllogism.

FORMAL LOGIC.

BOOK II.

SECTION I.

LIMITATIONS UPON THE FORM OF JUDGMENTS, &c.

(77.) In the present section, it is proposed to trace the limitations upon the form of judgments, the superiority of the first figure of categorical syllogism, and the possibility of true conclusions from false premises, to a common *à priori* ground in the very constitution of the understanding itself. The ground in question is a simple property of the understanding-conception, Substance, and may be stated as follows. Substance, or the substratum of phenomena, (*i.e.* the thing that is,—but is not phenomenon,) can never become a predicate.

For the conception of Substance may be defined as that which is thought as remaining when all possible predicates have been ab-

stracted from it. It is therefore impossible to make it a predicate, for nothing is left which can become its subject; and were we to attempt to predicate it of phenomena, we must previously think a substratum for these phenomena, and should therefore only be predicating the simple conception-substance of itself, which is absurd.*

Law between the predicate and copula of categorical propositions.

(78.) This property of the understanding-conception, Substance, will immediately explain the reason of the law between the predicate and copula of categorical propositions. This law,

* It is necessary to put the reader on his guard against a certain species of categorical judgments which appear to militate against the observations in the text, and to contain the conception of substance in the predicate as well as subject. The predicate in these judgments contains matter of such a nature as to determine it to a particular object, *e. g.* 'that man travelled with me yesterday.' In this judgment, taken alone, I really only think of the existing man before me, and predicate of him all that is contained in my conception of his having travelled with me yesterday. But the instant after making such a judgment as this, I might very probably convert it in my own mind, and think first of the existing man with whom I travelled yesterday, and afterwards predicate of him that he then stood before me. And the case with which the understanding can thus at pleasure make either term a subject containing the conception of substance, very naturally produces a false semblance of that conception being in the predicate.

which has already been stated in Art. 33, is repeated here :—

Affirmative copulas have undistributed predicates ; negative copulas have distributed predicates.

For, inasmuch as the predicate cannot contain the conception of substance, it is not thought in respect of its sphere, or the things that are contained under it, but in respect of its matter, or the representations contained in it. This term is accordingly a mere conception, which is never formally determined as to its quantity, and the precise limits of its sphere must always remain unknown. The limits of the sphere of the subject cannot, therefore, be exactly compared with those of the sphere of the predicate, but the former term must either be placed wholly in or wholly out of the latter. If it is placed wholly in, it is compared with only a part of the sphere of the predicate ; if it is placed wholly out, it is compared with the whole. From these considerations it is immediately evident, that the quantity of the predicate is always undistributed in affirmative, and distributed in negative judgments.

There is no formal proposition of identity.

(79.) For if the subject is single, it evidently cannot be identical with the predicate which is a conception. But if the subject is a conception, it must be considered either as to its partial representations, *i. e.* what is thought in it, or else as to its sphere, *i. e.* what is thought under it. In the first case the conception in the subject must be literally the same as the conception in the predicate, and the result would be a tautology, but not a judgment: in the second case the subject, which refers to the sphere or aggregate of individuals, cannot of course be identical with the predicated conception, the quantum of whose sphere is formally indeterminate. In neither case therefore could there be a formal proposition of identity. It need hardly be observed, that in the proposition 'A is identical with B,' the identity is expressed in the matter, and not in the form.

Figures of Categorical Syllogism.

(80.) The great advantages in elegance and perspicuity that the first possesses over the other three figures, have been already mentioned in the first book; and the ground of this superiority may now be derived from the

considerations introduced at the commencement of this section.

It has been shewn in Art. 77, that the conception substance is never placed in the predicate of a categorical proposition. Hence a conception, which in the subject is considered as to its sphere, (or the aggregate of individuals that are contained under it,) in the predicate is considered as to its contents, (or the representation that is contained in it as a mere conception). Any change then in the situation of a term introduces the necessity of a change in the manner in which it is thought. Now in the first figure, both subject and predicate of the conclusion retain the same position which they held in the premises, and consequently no such change in the manner of thinking them is necessary. But in the second figure, the major term changes its place from subject in the major premiss to predicate in the conclusion; and in the third figure the minor term changes its place from predicate in the minor premiss to subject in the conclusion, and consequently a change takes place in the manner of thinking one extreme in each of these figures. Again, in the fourth figure neither of the extremes hold the same position in the conclusion which they hold in the premises, and consequently two changes in the

nature of the terms take place. In this manner, then, it is sufficiently easy to account for the superiority of the first, and inferiority of the fourth, to all the other figures. For all but the first involve the necessity of some change in the manner of our thinking one at least of the extremes; and the fourth involves two such changes. If the reader will make the experiment of different moods in different figures, he will become immediately conscious that their comparative merits entirely depend on the cause alleged. Perhaps the mood E I O is the fittest for the experiment, as it is sound in all figures.

True Conclusions from False Premises.

(81.) True conclusions may be logically deduced from false premises in every correct form of categorical syllogism.

This proposition has been formally demonstrated in the first book, by means of the symbolical expression of the syllogistic laws.

The following is another rather preferable proof, which could not with propriety have been introduced there, as it rests upon certain considerations from Transcendental Logic.

As no categorical proposition is either formally identical, or formally exhaustive, (which

latter form would really be negatively identical, since it would assert the identity of $\overline{\text{not B}}$ with A,) it follows that no categorical proposition completely determines the whole of one term with respect to the whole of the other. For instance, in the proposition 'No A is B,' each term is placed in the external sphere of the other, but whereabouts in it, is quite undetermined. Again, in the proposition 'All A is B,' B is a conception, the excess of whose sphere above that of A is also undetermined, as it may vary from nothing to infinity. Now the indeterminate parts of the premises can never be introduced in the conclusion, which must follow from them necessarily, and therefore depend on the determinate alone. Hence it is evident that the materially necessary parts of the premises are invariably less than those which are formally necessary. If then we suppose an error in the indeterminate, and therefore unavailable parts of the premises, they will of course be false, although the conclusion, which is materially dependent on the remaining parts of those premises, is itself true.

It ought to be, if it is not, an axiom in an *à priori* science, that the general proof should invariably precede all reference to particular examples. But the reasoning in the last paragraph may now be elucidated, by taking as an

example the mood A A A. The general form of a syllogism in this mood is the following:

All B is A,
All C is B,
Therefore All C is A.

In this syllogism, the indeterminate parts of the terms are the excess of A above B, and of B above C, and these parts are accordingly unavailable in the conclusion. For it is only so far as C agrees with B, that it agrees with what B agrees; and in the same manner it is only so far as B agrees with A, that C, which agrees with B, can be concluded to agree with A. Let us then assume an error in the comparison of that part of B, which exceeds C, with A. Still A will be predicated of so much B as agrees with C, and consequently the conclusion will be true, though the major premiss is false.

The following is an example of a sound syllogism, of the form A A A in the first figure, in which the major premiss is false, though the conclusion is true:—

'All animals are quadrupeds,'
'All horses are animals,'
Therefore 'All horses are quadrupeds.'

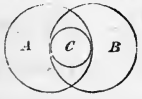
We subjoin three diagrams of this form of syllogism, in which the conclusion is true, though one or both premises are false. In

Fig. 1, both premises are false; in Fig. 2, the major premiss is false; and in Fig. 3, the minor premiss is false.

Fig. 1.

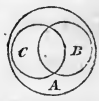
False, 'All B is A.'
False, 'All C is B.'
True, 'All C is A.'

Fig. 2.



False, 'All B is A.'
True, 'All C is B.'
True, 'All C is A.'

Fig. 3.



True, 'All B is A.'
False, 'All C is B.'
True, 'All C is A.'

These diagrams will also represent many other forms of syllogism, in which the conclusion is true, though one or both premises are false. For instance, if A be taken as the middle term, B as the major, and C the minor, Fig. 1 will represent the mood A E E in the second figure with a true conclusion, though both its premises are false. Again, if C be taken as middle term, A as major, and B as minor, Fig. 2 will represent the mood E I O in the first figure having its conclusion and minor premiss true, but its major premiss false. And similarly a great many other cases might be adduced, to which the above diagrams would be equally applicable.

This manner of proof may easily be extended to the other forms of syllogism. For instance,

in the hypothetical syllogism the antecedent contains the grounds of the truth of the consequent; but as it may also contain much more, their exact limits cannot be determined. The truth therefore of the consequent will be only formally, and not materially dependent on some part of the antecedent; and if an error is introduced in the minor premiss of a syllogism in the modus ponens, and in that part of it which does not constitute one of the grounds of the consequent, the result will be a true conclusion, though one of the premises is false: *e. g.* 'If the whole of the —— regiment were going to Canada, Captain A. would go; but the whole of the —— regiment are going to Canada; therefore Captain A. will go.' Now the antecedent contains all the necessary grounds for the truth of the consequent, and a great deal more besides; and consequently our minor premiss, which states that the whole regiment is going, might be false, and yet the conclusion that 'Captain A. is going' true.

As the conclusion must always be true if the premises are true, and will sometimes be true when they are false, it follows that the probability of the truth of the conclusion must always be rather greater than the probability of the truth of the premises.

Conclusions of the Reason.

(82.) The limitation which the understanding imposes upon the actual use of the reason, is very well calculated to place in a clear and strong light the distinct functions of the two faculties in every categorical syllogism; it is therefore briefly re-considered here.

The reason can deduce a conclusion from premises of the form I O in the first figure, by precisely the same mental operation as from the premises A A, or premises of any other legitimate form. These propositions are of the form

'Some B is A;
'Some C is not B:'

from which the conclusion may be logically deduced, that 'Some C is not some A.'

But this conclusion, though derived by the same function of the reason as any other legitimate conclusion (*i. e.* by a conjunction in the consciousness of two acts of the understanding), is nevertheless absolutely worthless, as it may be predicated *à priori* of any objects of which the understanding can think. For whatever be the nature of the hypothesis respecting the relation of C and A, (*e. g.* let 'All C be identical with all A,') still will it be true that 'Some C is not some

A.' And here therefore we find the logical reason performing its regular office in complete blindness, and quite independently of the nature of the result when considered in reference to the understanding.

SECTION II.

MODALITY OF SYLLOGISM.

(83.) Modality has been already defined as the determination of a judgment in respect of its relation to truth. If the matter of the judgment is merely in accordance with the *à priori* laws of thinking, the judgment is, in respect of its modality, problematical, or of the lowest degree: if it is in accordance not only with those laws, but also with the matter of the senses, it is assertive, or of the second degree; but if one of these *à priori* laws becomes the matter of the judgment, the latter is, in respect of its modality, necessary, or of the highest degree.*

As the formal use of the reason is quite independent of the matter of judgments, which at the same time determines their modality, it follows that this point of judging cannot have any influence on the nature of the conclusion in respect of its categorical form. But this remark does not extend to the modality of

* Vide Arts. 25, 26, on this subject.

the conclusion, which may in some measure be determined by that of the premises, and the extent to which one is a criterion of the other will supply the topic of the present section.

(84.) In order to place this subject in as clear a light as possible, it will be necessary to say a few words on the different sides from which the modality of a conclusion may be viewed. And in the first place, great care must be taken never to confound the modality of this proposition, 'that such a conclusion follows from such premises,' with the modality of the conclusion considered merely as to its own matter, and quite independently of its grounds.

The former modality is always of the highest degree, as it constitutes the very essence of a conclusion that it follows necessarily from its premises; whereas the real modality of the conclusion depends on the peculiar nature of its matter, and is determinable in the same manner as that of any other judgment.

But this distinction will become more apparent, when the above proposition assumes its appropriate form of a hypothetical, in which the conclusion is the consequent, and the premises the antecedent. It may then be stated thus: If such and such premises are both true, it will follow that such a conclusion is true. Now the relation between these

judgments is unquestionably necessary, as it consists in those laws of the reason by which the syllogism is known to be a correct one; but this is no criterion whatever for the modality of the judgments themselves, which constitute the matter of the hypothetical, and are therefore only propounded problematically. Before proceeding any further, an example will throw some light upon the foregoing remarks.

'All men are liars;'
'Obadiah is a man;'
Therefore 'Obadiah is a liar.'

Now the modality of this conclusion, considered in reference to the premises, is of the highest degree, or necessary; for the proposition that 'Obadiah is a liar' follows necessarily from the two propositions that 'all men are liars,' and that 'Obadiah is a man.' But the modality of this conclusion considered by itself is by no means necessary, since no necessity is contained in the proposition that 'Obadiah is a liar,' for no contradiction is involved in the supposition that he always tells the truth.

As we shall have occasion to recur to these two views of the modality of a conclusion, we shall designate them by the terms 'proper,' or that of any judgment considered merely as to

its own nature, and 'consequential,' or that which depends on its reference to the judgments from which it is deduced.

(85.) The proper modality of a conclusion cannot be fully determined by that of the premises, for the modality of the premises depends on their matter, and therefore on the middle term which occurs in each of them. But the conclusion will be unaffected as to matter, and therefore as to modality, by any change in the matter of the middle term, provided its formal quantity is preserved. Hence it follows that a change is possible in the modality of the premises, while that of the conclusion remains the same, and therefore that the modality of the one can never be fully determined by that of the other. This will appear from the following example. Let the two premises be

'All animals are organic beings;'

'All horses are animals.'

These propositions are analytical, and therefore necessary; and the conclusion derived from them, that 'All horses are organic beings,' is also analytical and necessary. But provided the formal quantity of the middle term 'animals, be retained in each premiss, any other matter may be substituted for it without affecting the legitimacy of the reasoning. Thus let the term 'cows' be substituted for

the middle term 'animals,' 'All cows are organic beings; all horses are cows; therefore all horses are organic beings.' Now the same conclusion has been logically deduced from these as from the original premises, and consequently its modality is the same in each case. But in the former syllogism the modality of both the premises was necessary; whereas in the latter, one of them is so far from being necessary that it is not even true. Hence it is evident that the nature of the premises can never be a complete criterion for the proper modality of the conclusion. There is, however, one law which will enable us to arrive at some sure knowledge on this subject, and may be stated thus: The modality of the conclusion is never of a lower degree than the lowest in either premiss.

(86.) Previous, however, to the consideration of this law, it will be necessary to shew why the case of two problematical judgments must be entirely put out of the question: for two judgments of this modality always leave the possibility of such a disjunctive relation existing between them, that they are never assertively true simultaneously.* No conclusion,

* It is necessary to distinguish between events that are 'simultaneously possible,' and 'possible simultaneously.' The first signifies that 'each is at the same time possible to happen;' the

therefore, can be deduced from them: but the truth of this remark will become more evident by an example. Let us suppose that a box contains only black and white balls, of which I abstract several, and put them in a bag without observing their colour: I may then state as problematical judgments—

'All the balls in the bag may be white; several black balls may be in the bag.' But I cannot deduce from these judgments even the problematical conclusion that 'several black balls may be white,' although such a syllogism in respect of its mere rational form (*i. e.* A I I in the first figure) would be perfectly legitimate. It is evident in this example that a disjunctive relation exists between the two premises, and consequently that they can never be true simultaneously, though either may be true when taken alone. As however the assertive modality of either premiss would destroy the possibility of such a relation, the objection will only apply to those cases in which both are problematical.

other, that 'both may possibly happen at the same time.' If I put my hand into a bag and draw out only one ball, I may draw out either a black one or a white one, and these events are therefore simultaneously possible. But as one ball cannot be both a black ball and a white ball too, these events are not possible simultaneously. The judgments in the example in the text, and also in every disjunctive proposition, are simultaneously possible, but not possible simultaneously.

(87.) After the exclusion of this particular combination of premises, five others will remain to which no such objection can be offered. These will accordingly come under the law, that the modality of the conclusion is never of a lower degree than that in the weakest* premiss.

To attempt a strict *demonstration* of any law respecting the operations of the Reason, involves the absurdity of making that faculty both judge and defendant in its own case: for in every proof the reason must tacitly assume the validity of its own laws, and any pretended demonstration of them from themselves is open to the objection of reasoning in a circle. It is useless therefore to sue the reason in its own court. All that can be done in a question respecting its functions, is to place it in as axiomatic a light as possible, and admit as final the decision of the faculty itself. In the present instance it is perhaps sufficient to observe, that inasmuch as the connection between the major and minor terms in the conclusion is entirely dependent on their previous comparison with the middle term in their respective premises, this connection must be of at least as high a degree as

* By the term 'weakest' that premiss is intended, whose modality is of at least as low a degree as that of the other premiss.

the lowest between the middle term and either extreme. And the same reasoning will also make evident the impossibility of logically deducing from the premises a higher degree of modality for the conclusion,* though such may perhaps exist. It will therefore be necessary to introduce the distinction of 'proper' and 'derived' modality, for the purpose of avoiding those long periphrases which would otherwise be perpetually recurring.

(88.) Perhaps the only great logical error of which Aristotle is guilty in his Analytics, refers to this very point of the modality of syllogism; and as an exposure of the fallacy will supply the best explanation of the last few paragraphs, we shall briefly consider it here.

The following passage will be found in the ninth chapter of the first book of the Former Analytics:—

Συμβαίνει δέ ποτε καὶ τῆς ἑτέρας προτάσεως ἀναγκαίας οὔσης ἀναγκαῖον γίνεσθαι τὸν συλλόγισμόν, πλὴν οὐχ ὁποτέρας τυχεν, ἀλλὰ τῆς πρὸς τὸ μεῖζον ἄκρον, οἷον εἰ τὸ μὲν Α τῷ Β ἐξ ἀνάγκης εἴληπται ὑπάρχον ἢ μὴ ὑπάρχον, τὸ δὲ Β τῷ Γ ὑπάρχον μόνον οὕτως γὰρ εἰλημμένων τῶν προτάσεων ἐξ ἀνάγκης τὸ Α τῷ Γ ὑπάρξει ἢ οὐχ ὑπάρξει. Επεὶ γὰρ παντὶ τῷ Β ἐξ ἀνάγκης ὑπάρχει ἢ οὐχ ὑπάρχει τὸ Α, τὸ δὲ Γ τι τῶν Β ἐστί, φανερὸν ὅτι καὶ τὸ Γ ἐξ ἀνάγκης ἔσται θάτερον τούτων.

* This law is precisely analogous to the mechanical axiom that every chain is of the same strength as its weakest link.

(*Translation.*)—It happens in some cases that if one premiss is necessary the syllogism becomes necessary (*i. e.* the conclusion of the syllogism), not however either premiss at random, but that which involves the major extreme; just as if, for instance, B is assumed to be A or not A, of necessity, and C is assumed merely to be B (*i. e.* assertively, not necessarily); for the premises being thus assumed, C will be A, or will not be A, of necessity. For since 'All B is A, or is not A,' of necessity, and 'C is a part of B,' it is evident that C will be one of these things (*i. e.* 'A or not A') of necessity.

Now as merely assertive judgments can only have empirical grounds for their truth, it follows that their predicates are stated of the sphere or individuals contained under the conception of the subject, and not of the conception itself. For a conception can only be predicated of another conception, (prior at least to the empirical consideration of the sphere of the latter,) either by being a superior conception, in which case the judgment is analytical, or else by some *à priori* law; but in either case the judgment is necessary, and therefore more than merely assertive.

Now, by the hypothesis, the minor premiss in the above syllogism is assertive, and consequently the middle term B is only predicated

of the minor term C in respect of its sphere, and not of its matter. But the truth of the conclusion (considered as such) depends entirely on this minor premiss, and in that judgment, therefore, A must be predicated of C in respect of its sphere and not its matter. But when a conception is predicated only of the sphere of another, the judgment cannot be necessary, as it involves no *à priori* law of thinking, and conveys no certainty that an exception may not be found on some future occasion. Hence the derived modality of the conclusion that 'all C is A, or is not A,' can never exceed the assertive or second degree, which is that of the weakest premiss. Let us take the following example:

'All members of Caius College are members of the University. Several Norfolk men are members of Caius College. Therefore several Norfolk men are members of the University.'

Now the major premiss of this syllogism is analytical, and therefore necessary, for it constitutes a part of the conception of a member of a college that he should be a member of the University. But the minor premiss on the contrary is merely assertive, as it is by no means necessary to our conception of Norfolk men that several of them should be members of Caius College. And the conclusion is also

merely assertive, as it does not necessarily enter into our conception of Norfolk men that they must be members of the University.

It is evident from this example, that only an assertive conclusion can be deduced from a necessary major and an assertive minor premiss. But this law regards the derived modality alone, and leaves the proper modality quite undetermined. For a trifling alteration in the example just given will render the proper modality of the conclusion necessary, and leave that of the premises unaltered. Let the minor term be changed into 'Several members of the University who reside in Norfolk;' the minor premiss will still be only assertive, as it is not necessary that any one of these men should be a member of Caius College; but the conclusion will be analytical, and therefore its proper modality will be necessary.

But, that Aristotle never intended to say that the conclusion from premises so assumed might sometimes* be necessary in its own nature, and sometimes only assertive, appears from his giving this proof in the general symbols A, B, C; and also from his predi-

* The restriction contained in the word ποτε, evidently alludes to the limitation of the law to those cases in which the major premiss is necessary, and the minor assertive.

cating necessity of the syllogism, and not merely of the conclusion. Neither is he merely alluding to the consequential modality of the conclusion, for he distinguishes between the proper and consequential modalities more than once, and particularly in the middle of the following chapter. So that his evident meaning is this: if a necessary major premiss and an assertive minor premiss be assumed in the first figure, that modality which can be derived from that of the premises for the conclusion as a judgment considered by itself, will be necessary and not merely assertive.

(89.) A fallacy involving a breach of the same law is to be found at the commencement of the nineteenth chapter of the first book of the Former Analytics.* Aristotle here lays down as a general rule, that if one premiss is necessary and negative, and the other problematical and affirmative, an assertive conclusion may be deduced from them.

"For let 'All B be necessarily not A,' and 'All C be possibly A:' if the negative premiss is converted, 'All A will be necessarily not B;' but 'All C may possibly be A;' there will therefore be a syllogism in the first figure to the effect that 'All C is possibly not B.' But

* This passage is at page 97 of Bekker's 8vo. Edition, Oxford reprint: Ἐι δ' ἡ μὲν ἐξ ἀνάγκης —— τεθείη τὸ στερητικόν.

it is evident, moreover, that 'All C will *be* not B.' For let us assume that 'Some C *is* B:' if then 'All B is necessarily not A,' and 'Some C is B,' it follows that 'Some C cannot be A,' which is absurd, as by the original hypothesis, 'All C may be A.' Therefore, &c."

This reasoning is extremely ingenious, but not less sophistical. It will be found to hinge upon the very fallacy which has just been exposed in the last paragraph. For the conclusion which Aristotle wishes to deduce, is assertive, viz. 'All A *is* B:' he accordingly assumes the assertive contradictory of this conclusion as the minor premiss of the first syllogism in an indirect proof, and from this assertive minor, and the original necessary major premiss, fallaciously deduces a necessary conclusion, to the effect that, 'Some C cannot be A.' And as this conclusion is at variance with the other premiss that 'All C may be A,' he infers that his assumption of the contradictory of the proposition 'All A is B' was unwarranted, and therefore concludes that 'All A is B.' Now the necessity of the conclusion that 'Some C cannot be A' was merely consequential and not proper, and the legitimate conclusion that 'Some C is not A' is not at all opposed to the original minor premiss that 'All C is possibly A.' For this, as well as

every other problematical conclusion, contains the conception of the possibility of the contrary. The proposition 'All C is possibly A' is therefore perfectly compatible with the proposition that 'Some C is possibly not A.' And it must be observed that the assertive modality of the conclusion that 'Some C is not A,' arises from the assumption of the assertive premiss that 'Some C is B,' which latter proposition states more than the premises would warrant in the conclusion of the original syllogism, though it is by no means contradictory to it. We will bring the question to an *experimentum crucis,* which will render the fallacy immediately evident. This will be most readily effected by taking a particular example, and carrying out the whole argument in precisely the same form as that in which it is given by Aristotle.

Let a bag contain several balls whose colour is unknown, and may therefore possibly be white or black, or any other colour. The necessary and negative premiss may then be, 'No white balls are black balls,' and the problematical affirmative, 'All the balls in the bag may be white balls;' from which Aristotle's reasoning would deduce as conclusion, that 'none of the balls in the bag *are* black balls.' His proof would run as follows: 'Let some of the

balls in the bag be black balls; as no black balls can be white balls, it follows that some of the balls in the bag cannot be white balls. But this is absurd, for by the hypothesis all the balls in the bag may be white. Therefore, &c.'

This species of fallacy will become yet more apparent by stripping it of the syllogism with which it is connected, and proving by its means that every judgment which is true problematically, must also be true assertively. Let the judgment be, 'All A may possibly be B.' It will follow from this that 'All A is B.' For if it is false that 'All A is B,' it must necessarily be true that 'Some A is not B.' But this is absurd, as by the hypothesis 'All A may be B.' Hence it follows, that the assumed falsity of the proposition 'All A is B,' must itself be false, and therefore that 'All A is B.'

Both of these fallacies of Aristotle are of considerable importance, as they violate this fundamental principle of the modality of syllogism, namely, that the derived modality of the conclusion is the same as that of the weakest premiss.

(90.) There is however another fallacy, very near the end of the twenty-eighth chapter of the same book, which is introduced here rather

as a curiosity than for any other reason, as in all probability it is the only instance of a false mood and figure in the whole work. It is stated in this passage that the denying B of H is exactly equivalent to identifying B with some T, where T has been previously assumed to represent the whole external sphere of a certain term E, which is itself a predicate of H. This paralogism is of the form A E E in the first figure, which has an illicit major, or E A E in the fourth figure, which has an illicit minor.*

It is rather remarkable, that, notwithstanding Aristotle's entire rejection of the fourth figure, he has introduced it once in this very chapter, in the mood A A I.†

* Page 115, Τὸ γὰρ μὴ ἐνδέχσθαι τὸ B, κ. τ. λ.

† Page 112, Εἰ δὲ τῷ H τὸ B ταὐτόν, κ. τ. λ.

APPENDIX.

The following are a few examples in which the reader can try his skill in detecting fallacies, determining the peculiar form of syllogisms, and supplying the suppressed premises of enthymemes. The arguments alone have been adopted from the different authors whose names are attached, as alterations in the mode of expressing them have invariably been found necessary to bring them a little nearer the simple syllogistic forms. Several of the examples contain more than one syllogism.

(1.) None but those who are contented with their lot in life can justly be considered happy. But the truly wise man will always make himself contented with his lot in life, and therefore he may justly be considered happy.

(2.) All nations, whose commerce has been very extensive, have reached a great height in refinement and luxury. The Romans reached a great height in refinement and luxury. Therefore the Romans must have had a very extensive commerce.

(3.) A really terrible enemy would never excite so small a degree of fear that any other passion could master the feeling. But there is no passion so weak that it cannot master the fear of death. Therefore death is no very terrible enemy.—*Bacon.*

(4.) None but the contented are happy; the good are happy; therefore they are contented.

(5.) If there is a possibility of the existence of God, nothing can be more evident than that men ought to live virtuously and piously, and that vice is the most absurd thing in nature. But that God exists is perfectly possible, as no demonstration can be given of the contrary. Therefore men ought to live virtuously and piously, and vice is the most absurd thing in nature.—*Clarke.*

(6.) If all cats are animals, and all animals are organic beings, it follows that all cats are organic beings. But all cats are organic beings. Therefore all cats are animals, and all animals are organic beings.

(7.) A statesman should particularly avoid anything that tends to bring him into contempt. Idle and frivolous duels will probably have this effect, and he should therefore particularly avoid them. — *Taylor's Statesman.*

(8.) All intelligible propositions must be either true or false. The two propositions 'Cæsar is living still,' and 'Cæsar is dead,' are both intelligible propositions; therefore they are both true, or both false.

(9.) God acts according to laws because he knows them, he knows them because he has made them, he has made them because they bear a certain relation to his wisdom and power; therefore God acts according to

laws because they bear a certain relation to his wisdom and power.—*Montesquieu.*

(10.) Blessed are the pure in heart, for they shall see God.

(11.) None but the good are really great, and all the good are happy. The slaves of passion are never really great, and therefore they are never happy.

(12.) No man who is in London can be in York. As no person has told me where Mr. A is, for all I know to the contrary he may be in York. Therefore I conclude that he is not in London. For if this conclusion is false, it must be true that he is in London. But no man that is in London can be in York. Therefore Mr. A is not in York, which is contrary to the original hypothesis that he may be in York; and therefore the second hypothesis, that he is in London, must be false, and Mr. A is not in London.

(13.) All God's gifts are intended for use. Our foresight and power over the future are God's gifts. Therefore it is intended that we should use our foresight and power over the future. But Slavery precludes all possibility of the exercise of these powers; it is therefore opposed to the intentions of Providence —*Channing.*

(14.) Many things are more difficult than to do nothing. Nothing is more difficult to do than to walk on one's head. Therefore many things are more difficult than to walk on one's head.

(15.) If God does not grant his grace upon the same conditions to all mankind, he is a respecter of persons. But God is no respecter of persons. There-

fore God grants his grace upon the same conditions to all mankind.

(16.) He that is of God heareth God's words: ye therefore hear them not, because ye are not of God. —*John*, c. viii, v. 47. *Quoted from Whately's Logic.*

(17.) It is highly probable that all persons who have established a new religion entirely subversive of the old, have suffered persecution. The first preachers of Christianity were such persons. It is therefore highly probable that they suffered persecution. — *Paley's Evidences.*

(18.) The men who barter their eternal welfare for temporary gratifications are very deficient in real wisdom. But the men who are thus deficient are by no means few. Therefore the men who barter their eternal welfare for temporary gratifications are by no means few.

(19.) None but Whigs vote for Mr. B. All who vote for Mr B. are ten-pound householders. Therefore none but Whigs are ten-pound householders.

(20.) The waking state succeeds the sleeping, and the sleeping succeeds the waking; things become cold from having been hot, and hot from having been cold; men can only become taller from having been shorter, and shorter from having been taller. Thus all contraries mutually produce, and are produced from, each other. But the states of life and death are contrary to each other. Therefore the state of life succeeds that of death, as that of death does that of life.—*Plato's Phædo.*

(21.) If the Mosaic account of the cosmogony is strictly correct, the sun was not created till the fourth day. And if the sun was not created till the fourth day, it could not have been the cause of the alternation of day

and night for the first three days. But either the word 'day' is used in Scripture in a different sense to that in which it is commonly accepted now, or else the sun must have been the cause of the alternation of day and night for the first three days. Hence it follows that either the Mosaic account of the cosmogony is not strictly correct, or else the word 'day' is used in Scripture in a different sense to that in which it is commonly accepted now.

(22.) Men who would peril their own lives and those of their fellow-creatures on no better pretext than that of maintaining a reputation for courage, would unquestionably engage in duels upon very slight provocation. But none except very weak men would ever peril any human life with such an object alone, and we therefore conclude that none but very weak men would engage in duels upon very slight provocation.

(23.) Laws, in the widest acceptation of the word, are the necessary relations which derive their origin from the nature of things. The Deity, therefore, has his laws, for he bears a certain relation to the universe as its creator and preserver.—*Montesquieu.*

(24.) Suffering is a title to an excellent inheritance; for God chastens every son whom he receives. (Quoted literally from Jeremy Taylor's Holy Living and Dying.) This sentence may be put under the following form: All whom God receives, he chastens; all who suffer, God chastens; therefore, all who suffer, God receives.

(25.) To do a certain evil for a problematical good is contrary to the spirit of Christianity. But to hurry a great criminal into the presence of his Creator, and this for the sake of the very questionable advantage which

capital may have over other severe punishments in deterring others from crime, is to do a certain evil for a problematical good. Therefore capital punishment is contrary to the spirit of Christianity.

ADDITION TO NOTE p. 117.

The complete elimination of the indeterminate symbols x, y, m, n from the equations on note to p. 117, will furnish additional equations representing the general laws of Categorical Syllogism in their simplest form: each of whose solutions will correspond to a possible mood.

It is unnecessary to insert the process of elimination; but it will be seen without difficulty that the equations thus obtained are the following:—

Quality..... $p_1 + p_2 + p'_3 = d + 2u$.....(1).

Laws of particular premises and particular conclusion. $\left.\begin{matrix}(s_1 - d)(s_2 - d) = 0 \\ (s_1 - d)(s'_3 - d) = 0 \\ (s_2 - d)(s'_3 - d) = 0\end{matrix}\right\}$..... (2).

I E O excluded as leading to illicit major. $\left\{(s_1 - d)(p_1 - d)(p'_3 - d) = 0\right.$...(3).

(1.) Implies that two of the quantities $p_1\, p_2\, p'_3$ must be $= u$, and a third $= d$, and admits therefore of 3 solutions.

(2.) Imply that any two or all three of the quantities $s_1\, s_2\, s'_3$ must $= d$ . . and admit therefore of 4 solutions.

The whole number of solutions therefore admissible from (1) and (2) is $3 \times 4 = 12$.

Of these one is rendered inadmissible by (3). The whole number of possible moods is therefore 11.

INTRODUCTION.

DEFINITION AND DIVISION OF LOGIC.

I. Logic, called by Whately "the science and art of reasoning," and by John Stuart Mill "the science of evidence or proof," is the science of the forms of thought," or "of those laws on which depends the truth of thought," and is defined by St. Thomas: "The science which teaches man how to order aright the acts of the intellect in the pursuit and acquirement of true science;" and again: "The science of the order to be followed in the acts of the intellect in the pursuit and demonstration of truth." Suarez says: "It is the proper office of Logic to give the means of acquiring true science,—which is done by showing what are its instruments, and by demonstrating their power and properties."

These words of Suarez, and the first three of the six definitions enumerated, apply, strictly speaking, only to Formal Logic, or Dialectics, of which we shall speak just now: so that the choice of a general definition is restricted to the two statements of St. Thomas and the definition immediately preceding them; while it is clear that choice is merely a matter of form, as all three express precisely the same thing.

II. In all of them three things are either expressed or implied, viz., **A**, an **Agent**; **B**, an **Act** according to some law or order; **C**, an **End**.

The Agent is **man**; the Act is **reasoning**; the End is **Truth**.

According to this view, the subject admits of the following division:

A. Man, as the **agent of the act** of reasoning;

B. Reasoning—**the act of the agent**;

C. Truth and certainty—**the end of the agent's act.**

This is only another way of putting the Scholastic division of Logic into **Formal** and **Material**; Formal Logic or Dialectics answering to the act of the agent (see definitions at p. 10, et seq., referred to at p. 17); Material Logic, to the end of the act. And, as Truth is something else besides the end of the act of reasoning, as it can be gained in other ways, and is manifested by laws outside our minds,—and as Material Logic has Truth for its matter, it follows that these laws must fall within the scope of this Material Logic. In this division a knowledge of the agent of the act is presupposed.

A distinction is often made between **Natural** and **Artificial** Logic, Natural Logic means the natural reasoning that leads men to Truth, or that would do so, if it were possible for them always to follow the light of reason. Artificial Logic may be briefly called the science of Natural Logic, for it does no more than give an exact and methodical shape to the rules delivered by nature; just as in music, or painting, or sculpture, the technicalities of the art merely throw natural rules into order and method.

And, as the art-student naturally acquires delicacy of perception in all that concerns his art; so does the study of Logic give delicacy of intellectual touch to distinguish Truth, and a peculiar power of discerning Truth, and of unmasking error when it lurks under the guise of Truth.

III. This being so, it is evident that, although the task of putting due order into the discourse of the mind is far more difficult than success in art or in science, it is nevertheless far more necessary; and that in science Logic is itself the "instrument of knowledge," and so must precede its acquisition, as St. Thomas says: "Necessity requires that, although it is more difficult than many other sciences, we should in learning begin with Logic, because all other sciences depend upon it,"[1] that is, they depend so far as our knowledge is concerned, on the accuracy of thought gained by Logic, and on the application of its rules to the matter of the science.

[1] Opusc. 70.

A.

THE AGENT.

THE AGENT.[1]

I. Definition of the Agent. II. Powers of the soul. III. Powers of the intellect. IV. Action of the intellect.

I. Definition. From the time of Aristotle, man has been defined "a rational animal;" he is a complete substance, composed of two incomplete substances—the body and the soul; the body being the **matter** of the substance, and the soul its **form.**[2] Hence it is said that the soul "informs" the body; and hence it is, through the action of its powers, the principle of man's life and activity. Created by God, and placed in the body to rule and direct it, the soul is the stable and permanent element in all the various processes of what we vaguely call our minds; and, being in itself a spiritual substance, is capable of existing and acting without the body, though in this life the two are inseparably united, and so closely that it is impossible for the one to act without the other being in some way, either directly or indirectly, affected.

II. Powers of the soul. Inherent in the soul,

[1] This brief sketch merely treats of what it is necessary to know of the mind of man, in order to study and understand Logic aright.

[2] See p. 75.

and producing by their action one or other of man's many vital processes, are three classes of powers or faculties:

1. **Vegetative powers**—nutrition, growth, generation—which belong to the soul in virtue of its connection with the body, and are common to plants, animals, and men.

2. **Sensitive powers**—*e.g.*, senses, imagination, instinct, sensitive memory—which also belong to the soul in virtue of its connection with the body: they are common to the animals and men.

3. **Rational powers**—memory (rational), intellect or understanding, and will—which belong to the soul itself, and in virtue of its own nature; hence to man as man.

III. **Intellect or Understanding** contains within it three powers, viz.:

1. **Conception,** the faculty by which we form ideas;

2. **Judgment,** the faculty by which we join together two ideas;

3. **Reasoning,** the faculty by which we compare and weigh judgments, and therefrom deduce conclusions.

IV. **Action of the Intellect.** By this term we can understand the processes of the three intellectual powers just enumerated; and thus the first thing to be considered under it will be the exercise of **Conception** in the **Formation of ideas.** The mind is a tabula rasa before it receives any impressions from without. It receives impressions, or the matter for ideas, through the senses, upon which the impression is made. By means of the "sensus

intimus" man becomes conscious of these impressions, of which the imagination then forms a picture or phantasm. Up to this point the cognition is merely a sensitive or sensible one, like that of animals. But, from the picture on the imagination, the intellect draws that element which is akin to itself, that is the immaterial incorporeal element, throws it into its mould—so to say—and the result is the "species intelligibilis," formed in the intellect itself, and representative of the exterior thing. When informed by the "species intelligibilis" of a thing, the intellect simply names that thing to itself with a mental word; and the mind is conscious of the possession of its idea. It must be borne in mind that the "species intelligibilis" is, like the intellect itself, purely spiritual and immaterial, and so is in no sense pictorially representative of the external object of sense, as is the phantasm of the imagination. For instance: the eye sees a fan-tail, and thus there arises an external sensation; the consciousness of this sensation obtained by the "sensus intimus," supplies the matter for the phantasm of the fan-tail, which is next formed in the imagination; and then in the intellect the "species intelligibilis," or spiritual representation of the fan-tail comes into being; whereupon the intellect, then by a simple word, says in and to itself, fan-tail. Again, a boy sees a triangle, of which he has first of all an external sensation, made conscious to him by the "sensus intimus"; anon a picture of the triangle paints itself on his imagination; from this picture or phantasm, which is probably a very imperfect representation of a triangle, his intellect

extracts an universal, perfect, "ideal" triangle, and on this he argues, and deduces from it all its properties.

Thus much for the idea, which, so far from being the lengthy matter this explanation would seem to imply, is practically an almost instantaneous process, and a simple indivisible act. Hence we say that, an idea flashes upon us in an instant.

The next thing to be looked at is **Judgment,** that is, the way two ideas are joined together. Having two or more "species intelligibiles," the intellect in putting them together produces a complex word or idea, called a judgment, or more popularly a statement: for in English the term judgment is often applied in common parlance to the conclusion or result of a train of reasoning, of which we shall speak next. To illustrate this complex word, or statement, or judgment, we will go back to our fan-tail. The intellect has the "species intelligibilis" of fan-tail, and of, say, tame and wild. From them it produces a complex word, saying, the fan-tail is tame, or the fan-tail is not wild; in the first statement affirming something by a positive "judgment"; in the second, denying something by a negative "judgment." And so, too, with the boy and his triangle. If he has the "species intelligibilis" of triangle and of scalene and isosceles, he may affirm by a positive judgment that the triangle is scalene; or deny something by the negative judgment that the triangle is not isosceles.

Lastly, the faculty of **Reasoning** comes into play. The intellect passes from one complex word or judgment to another, compares them, and either

CALIFORNIA

unites or separates them, and forms a new complex word or judgment, resulting from the comparison. For instance:

Every fish has fins;
But no fan-tail has fins;
Therefore no fan-tail is a fish.

When this new complex word or judgment, which is called the conclusion, is some truth which has no influence on our conduct, the faculty of Reasoning is called Speculative Reason. Instance the above comparison of fish, fins, and fan-tail; and again:

Secondary planets move round their primaries;
But the moon is a secondary planet;
Therefore the moon moves round its primary.

When the result of the argument is some action on our part, when we reason with a view to practice, the faculty is called the Practical Reason, and the process a practical one; *e.g.*, if I am led by the following argument to study the moon through a telescope, I exercise the Practical Reason:

Planets can only be satisfactorily studied through a telescope;
But the moon is a planet;
Therefore the moon can only be satisfactorily studied through a telescope,—and I must study it through a telescope.

And I employ the practical Reason when I argue that:

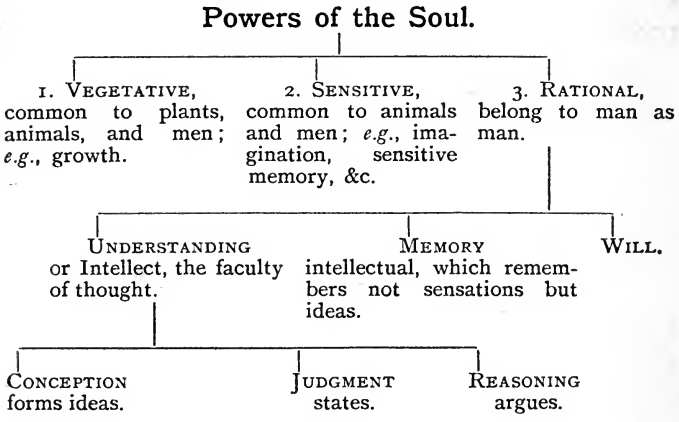
The means of advancing in my studies are to be adopted;
But steady conscientious application is a means of advancing in my studies;

Therefore steady conscientious application is a habit to be adopted or acquired,—and one which I will do my best to acquire.

Thus a Speculative Process differs from a Practical one, not in itself, but in respect of the end or object to which it is directed. The same faculty is employed in either case: the only difference is in the result aimed at.

All this internal discourse of the mind is called **Reasoning,** and its end is the clear knowledge of Truth. The order in which these acts of the intellect should be arranged is called the Logical or Rational Order: and so we come to Logic itself, or the **Act of the Agent,** or **Formal Logic.**

Before passing on to it, however, the matter just treated of may be made clearer by the subjoined scheme.



Powers of the Soul.
1. Vegetative, common to plants, animals, and men; *e.g.*, growth.
2. Sensitive, common to animals and men; *e.g.*, imagination, sensitive memory, &c.
3. Rational, belong to man as man.
Understanding or Intellect, the faculty of thought.
Memory intellectual, which remembers not sensations but ideas.
Will.
Conception forms ideas.
Judgment states.
Reasoning argues.

B.

THE ACT OF THE AGENT,

OR

FORMAL LOGIC.

CHAPTER I.

I. Definition of the act. II. Division of the act. III. Matter of the act. IV. Definition of terms. V. Division of terms.

I. Definition. See pp. 10—14.

II. Division. In the "Act of the Agent" there are two things to be considered, viz., its **Matter** and **Form.** Having seen what Logic is, and having besides looked at the intellect of man, which is the direct agent of Logic, we must conclude at once that the Matter of reasoning can be no other than those acts of the intellect which admit of being arranged suitably for the attainment of Truth, *i.e.*, ideas and statements or "judgments;" while the Form of Logic must be that disposition—or handling—of ideas and statements, by means of which the intellect attains its end of knowing Truth. We have already shown that this disposition or handling of ideas and statements, is that internal discourse of the mind which is called reasoning; and hence reasoning must be the Form of Logic.

III. Matter. As intellectual acts are more easily treated of by the use of signs, the word of the intellect or idea is known in Logic as a **Term,** and the complex word or "judgment" as a **Proposition.** Hence **Terms** and **Propositions** are the signs of the

matter of the "Act of the Agent," or of Formal Logic.

IV. Terms. Definition. Taken absolutely, a term is the external sign of what by a simple internal word has become the object of thought: thus fan-tail, tame, wild, virtue, triangle, scalene, isosceles, are terms.

Considered relatively, a term is defined by Aristotle "that into which every proposition[1] is resolved, as into subject and predicate," *e.g.*, our fan-tails—subject—are—interesting birds—predicate. Here the two terms are fan-tails and interesting birds, united by the verb are, which is neither a term nor part of a term, but the nexus or link joining one term to another.

V. Division of Terms. Terms have been divided into a number of classes, of which the following seem to be the chief. [It must be remembered that the various groups of classes, as they may be called, are strictly co-ordinate; and so it will be seen that the same term may often belong to many groups, though it can, of course, belong only to one class or subdivision of each group.]

(1.) Terms may be either **simple** or **complex.** They are simple when they consist only of one word, *e.g.*, man, house, triangle; complex when they consist of two or more words, or even of propositions, *e.g.*, tame fan-tail, bright blue sky, the fan-tails we fed, the house that Jack built.

(2.) A term may be **absolute** or **relative.** An absolute term denotes a thing in itself, *e.g.*, man, book, star; a relative term denotes a thing in rela-

[1] See p. 21.

tion to some other thing, *e.g.*, father, master, which denote man in relation to children or subordinates—satellite which denotes a secondary planet in relation to its primary. Terms so related are called **correlatives.**

(3.) Terms may be **abstract** or **concrete**; abstract, when they express a quality or attribute apart from the being of its object, *e.g.*, wisdom, folly, common-sense; concrete, when they express quality united with being, *e.g.*, man, wise, foolish, sensible.

(4.) Terms may be **singular** or **universal**; singular or individual terms are such as can be applied only to a single individual thing, *e.g.*, St. Thomas Aquinas, Aristotle, this ruler, this picture; universal or common terms are such as can be applied in the same sense to many things. Such application may be either:

(a.) **specific,** that which indicates the species of the thing to which it is applied, *e.g.*, the universal term man indicates that John or Thomas, to whom I apply it, is a rational animal.

(b.) **generic,** that which indicates the genus of a thing, or the wider division that is marked into classes by the species, *e.g.*, animal is the genus of man, scansores is the genus of parrot, wind is the genus of monsoon.

(c.) **differential,** that which distinguishes a particular species from all the other species under the same genus, *e.g.*, the universal term rational distinguishes man from all other species under the genus animal, the universal term hyperbolic distinguishes a certain species of orbit from all other species under the genus orbit.

(d.) **proper,** that which indicates something belonging to all the individuals of a species, as such, and applicable only to them, *e.g.*, reasoning is proper to man as such, and belongs only to man.

(e.) **accidental,** that which indicates something which, though not necessarily joined to the difference, is yet found in some individuals of the species, *e.g.*, black as applied to men, green to parrots, white to pigeons, red to roses.

Hence **genus, species, difference, property, accident, are all universals,** because many things do or can participate in them; they are also called **predicables,** because in every proposition that predicate which can be applied in the same sense to many things must be either genus, species, difference, property, or accident.

(5.) Lastly, terms may be **univocal, equivocal,** or **analogous,** which are not really three kinds of terms, but three ways of using them. A term is used **univocally** when it is applied to several objects in the same sense: thus boy is used univocally of John, Henry and James; and girl is used univocally of Edith, Margaret and Alice. A term is taken **equivocally** when it is used in several instances in quite distinct significations: thus the terms Jupiter and Mars are used equivocally of the heathen gods and the planets; and the term Great Eastern is used equivocally of a certain line of railway and a well known steamship. When a term is applied to two or more things in senses which are in some points identical and in some points different, the term is taken **analogically:** thus, according to **analogy of attribution,** which is found between

terms signifying things of different natures, yet all having a connection with some one thing, the term healthful may be applied to medicine, food, exercise, dwelling, and the like; while, according to **analogy of proportion**, which exists when a term is used in two quite distinct senses, standing nevertheless in similar relations to two other terms, we speak of the smile of a man, of fortune, of a meadow, or again of stormy weather, stormy tempers, stormy troubles. Analogy of proportion is what is commonly understood by analogy.

CHAPTER II.

VI. Definition of propositions. VII. Division of propositions. VIII. Properties of propositions.

VI. Propositions. Definition. A proposition is the verbal sign of the statement or, "judgment," or "complex word of the intellect," that is to say, it is the statement or judgment expressed in words, and hence Aristotle calls a proposition an **interpretation,** because it interprets the statement or judgment of the intellect. It may be closely defined as—a sentence in which one term is joined to another, or disjoined from it. The word term is used instead of things, because both terms may express the same thing, and because a proposition does not unite or separate things but the signs of things.

In examining propositions, it will be seen that, although terms and propositions are the matter of formal logic, propositions are the **direct** or **proxi-**

mate matter of reasoning or syllogisms, while terms are the **indirect** or **remote matter**; because, in point of fact, terms are the matter of propositions. They are so because propositions are made of terms formed into propositions by the verb *to be*, which, either explicitly or implicitly, is their nexus or copula, hence makes the proposition what it is, and hence is its **form**; *e.g.*, fan-tails are birds; fan-tails and birds are the two terms of the proposition, *i.e.*, its matter; the verb *are* is the nexus joining the two terms together, and making them into a proposition, *e.g.*, giving the proposition its form. The verb *to be* does this explicitly when it is expressed, as in the above proposition; it does it implicitly when, as in all non-explicit instances, it is implied in the verb used, *e.g.*, The fan-tails fly is logically equivalent to The fan-tails are flying; I came = I was coming; Fan-tails like petting = Fan-tails are liking petting.

VII. Division of Propositions. Like terms, propositions are divided into a number of classes, or co-ordinate group of classes. Of these the following are the chief:

(1.) Propositions may be either **simple** or **composite.** A simple proposition is one which contains only one subject and predicate, and cannot be resolved into other propositions, *e.g.*, This fan-tail is tame,—These colours are bright,—Delays are dangerous. Simple propositions are often called **categorical,** because they simply assert that the subject does, or does not agree with the predicate. A composite proposition is one which either implicitly or explicitly contains other propositions into which it may be resolved, *i.e.*, its subject or predicate

must be compound or composite as opposed to simple. Composite propositions may be:

(a.) Hypothetical or **conditional,** when something is affirmed or denied, not absolutely, but under some condition, *e.g.*, if the fan-tails are hungry, they will feed on my hand; If a heavenly body revolves round the sun, that heavenly body cannot be a fixed star; If man thinks, he must be rational. The truth of such propositions depends upon the **assertion** or **consequent** being a result of the **condition** or **antecedent,** hence upon the **nexus** between them.

(b.) Causal, when the predicate contains the reason of its union with the subject, *e.g.*, The fan-tails feed on my hand because they are hungry; Man thinks because he is rational; The earth is a planet because it revolves round the sun. The truth of such propositions depends upon the truth of the reason assigned, *e.g.*, the fan-tails might be in the habit of never feeding anywhere else but on my hand, whether they were hungry or not; and then it would not be true to say—the fan-tails feed on my hand because they are hungry, although they might be both hungry and feeding on my hand.

(c.) **Copulative,** when the proposition contains more than one subject, or more than one predicate, made into a single term by some negative or affirmative particle, *e.g.*, Both fan-tails and ringdoves have wings; Neither fan-tails nor ringdoves can fly very high; Plants live and grow; Animals and plants live; the drawing-master has brought some fine copies, both in crayons and water-colours. For these propositions are to be true; the single predicate

must apply to all the subjects, and the single subject must apply to all the predicates.

(d.) **Disjunctive,** when several subjects or predicates are included in a single term by a disjunctive particle, *i.e.*, one which implies an alternative, *e.g.*, I shall either come or go; The sun is either in motion or at rest; The soul is either a simple uncompounded substance, or a composite compounded substance. For such propositions to be true, one of the two or more predicates must apply to the subject; and, in the reverse case, one of the two or more subjects must apply to the predicate.

(2.) Propositions may be **singular, universal, particular,** or **indefinite**: singular, when the subject is a singular term, *e.g.*, Julius Cæsar was murdered in the senate house; The moon is in itself a dark body; Brutus is an honourable man; Thetis saved Hephaistos: universal, when the subject is a universal term, *e.g.*, all men are mortal; all the mythological personages of Homer fall into three groups; all the old Spanish comedies were of a thoroughly romantic character; All Downside boys remember Coxhead Sunday: particular when the predicate is either affirmed or denied of only part of the subject; in such cases the subject is called a particular term, *i.e.*, a universal taken with a limitation; *e.g.*, Some boys are troublesome; Some of the stories in the *Arabian Nights* are probably derived from Persian sources; Much modern philosophy is like a man having a hale and healthy look while the germs of fatal malady lie within him: indefinite, when nothing in the proposition shows whether the subject is used in a particular or in a universal sense,

e.g., Children are bright; Fan-tails are interesting; "The lunatic, the lover, and the poet, are of imagination all compact."

Practically, however, indefinite propositions are treated as universals when they either exclude all exceptions, *i.e.*, have **absolute universality**, *e.g.*, Man is a creature; Fan-tails are birds; or have universality in the **physical** order, *e.g.*, A dead tree cannot put forth green leaves; A dead man cannot return to life (*i.e.*, according to the ordinary laws of nature); —or have universality in the **moral** order, the exceptions to which depend on human freedom, *e.g.*, Mothers love their children; Countries are not liable to foreign invasion from civilized powers in time of peace.

(3.) Propositions may be **affirmative** or **negative;** affirmative when the predicate is affirmed of the subject, *e.g.*, Fan-tails are frolicsome; Man is a free agent;—A strong element of self-assertion is discernible in the Homeric character of Athenè;—negative, when the predicate is denied of the subject, *e.g.*, The fantails are not hungry;—Logicians are not tolerant of words that have no fixed, clear and clean cut meaning;—The portrait of Hubert Herkomer is not in the Grosvenor.

VIII. Properties of Propositions. The principal properties of propositions are (1.) **equivalence,** (2.) **opposition,** (3.) **convertibility.**

(1.) **Equivalence** is the sameness of force and signification existing between various propositions, (a.) They may be equivalent by a simple change of words, *e.g.*, All fan-tails are white, is equivalent to, There is no fan-tail which is not white;—All his

adversaries were crushed by his stinging compressed oration in *Scheriè*, is equivalent to, There was not one of his adversaries who was not crushed by his stinging compressed oration in *Scheriè*.

(b.) Propositions may be equivalent because they belong to a whole which can resolve itself into parts, and these parts taken together must be equivalent to the whole: thus, in the above examples, All fan-tails are white—a universal affirmative proposition—is equivalent to the sum of all the singular propositions, This fan-tail is white; and so too, All the adversaries were crushed, equals the sum of all the singulars, This adversary was crushed.

(2.) **Opposition** is the contrast or diversity existing between two propositions which have the same subject and the same predicate, and may be a difference either of **quantity,** of **quality,** or of **both combined.** Hence the opposition may be:

(a.) **Contradictory,** *i.e.*, both in quality and quantity, or when a universal affirmative proposition is opposed to a particular negative, or a universal negative to a particular affirmative, *e.g.*, All fan-tails are white, of which the contradictory is, Some fan-tails are not white, No fan-tails are black, of which the contradictory is, some fan-tails are black: again, All German critics are of opinion that Hamlet's madness is feigned, has its contradictory in, Some German critics are not of opinion that Hamlet's madness is feigned; and, No sources of polytheism were dried up by the advent of Christianity, has its contradictory in, Some sources of polytheism were dried up by the advent of Christianity.

From this it is clear that, of two contradictories

one must necessarily be true, and the other false; because, if they were both together true or false, we should be affirming and denying something of a thing in the same relation, which would be absurd; and because from the truth of one we infer the falseness of the other, and *vice-versâ*.

(b.) **Contrary,** when the opposition is in the quality of the propositions, and both are universals, *e.g.*, All fan-tails are white, of which the contrary is, No fan-tails are white; again, All planets are round, is contrary to, No planet is round; and No knowledge comes to us through the senses, has its contrary in, All knowledge comes to us through the senses.

Contrary propositions cannot both be true at once, for the same reason given in the case of contradictory propositions; but sometimes both contraries may be false. Thus, the falseness of one may be inferred from the truth of the other; but from the falseness of one the truth of the other may not always be inferred.

(c.) **Sub-contrary,** when the opposition is—as with contraries—in the quality of the propositions, which are not—like contraries—universals, but particular, *e.g.*, Some fan-tails are tame, opposed to, Some fan-tails are not tame; Many little maidens are dumb, opposed to, Many little maidens are not dumb; Many boys are fond of getting "twenty Latin lines," opposed to, Many boys are not fond of getting "twenty Latin lines."

Two sub-contraries may sometimes be true together, *e.g.*, in the example of the fan-tails. Both together, however, can never be false, or

their universal contradictories would both be true, and so two contraries would be true at once, which is impossible. Hence, the truth of one may be at once inferred from the falsity of the other, but not *vice-versâ*, *e.g.*, from the falseness of the propositions, Many little maidens are dumb, and Many boys are fond of getting "twenty Latin lines," which from experimental knowledge I may know to be false, I can at once infer the truth of the opposite propositions, Many little maidens are not dumb, and Many boys are not fond of getting "twenty Latin lines."

(d.) Subalterns differ in quantity only, *e.g.*, Every fan-tail is white, to which corresponds the subalternate, Some fan-tails are white; Every ancient nation believed more or less distinctly in a future state, has for its subalternate; Some ancient nations believed more or less distinctly in a future state.

Subalterns can both together be true or false; hence the truth of one cannot be inferred from the falseness of the other, or *vice-versâ*. But if the universal or subalternant proposition be true, the particular or subalternate proposition must be true also, because it is virtually contained in the universal, as a part is contained in the whole, *e.g.*, "Some fan-tail" is contained in "Every fan-tail," "Some nation" in "Every nation." If, however, the particular subalternate is true, it does not follow that the universal subalternant is true too, for the universal is not comprised in the particular, *e.g.*, the particular proposition, Some Carthaginian soldiers were enervated at Capua, is true; but the universal, All Carthaginian soldiers were enervated at Capua, is quite false. On the other hand, if the

particular subalternate is false, the universal subalternate is false, the universal statement must *co ipso* be false likewise, for it stands to reason that what is denied of a part cannot be affirmed of the whole, *e.g.*, the false particular, Some planet is triangular, tells me clearly enough that its universal, Every planet is triangular, cannot be true. Yet, from the falseness of the universal subalternant we cannot infer the falseness of the particular subalternate, for it is possible that what is not true of a whole may be true of a part, *e.g.*, from the false universal. All Carthaginian soldiers were enervated at Capua: we cannot infer that its particular subalternate, Some Carthaginian soldiers were enervated at Capua, is false. Hence, from the truth of the subalternant the truth of the subalternate may be inferred, but not *vice-versâ*; while, on the contrary, from the falseness of the subalternate the falseness of the subalternant may be inferred, but not *vice-versâ*. It will have been seen that the opposition between subaltern propositions is more nominal than real.

(3.) **Convertibility,** is the property by which the subject of a proposition may be converted into the predicate, or the predicate into the subject. More shortly, this conversion is the transposition of the terms of a proposition. The proposition to be converted or transposed, is called convertible or the **convertend**; the new one resulting from the transposition is called the **converse,** *e.g.*, $4=2+2$ is convertible into $2+2=4$.

Conversion may be **(a.) simple,** or **(b.) per accidens.** First of all, it must be noted that in both forms the quality must remain unchanged.

(a.) In **simple** conversion the same quantity is retained as well as the same quality, *e.g.*, No circle is a quadrangle, convertible into, No quadrangle is a circle; No tea-tray is a star-convertible into, No star is a tea-tray. Because, in simple conversion, the two judgments are identical, it follows that either both must be true or both false, and so the truth of one can be inferred from the truth of the other, or the falseness of one from the falseness of the other.

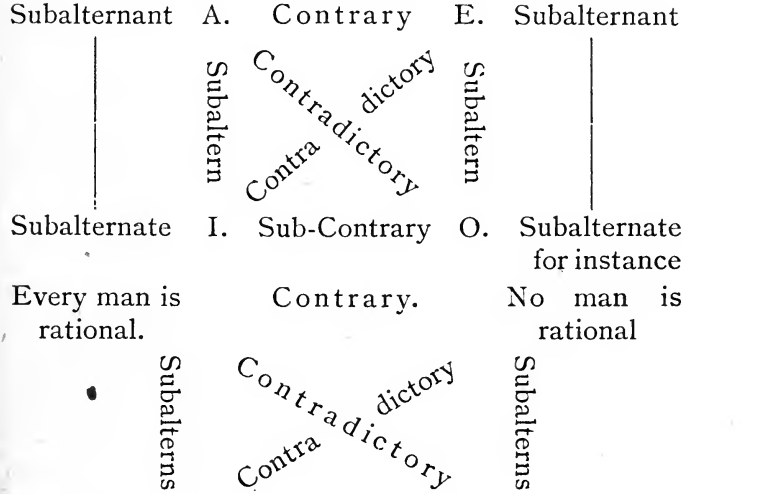
(b.) In Conversion **per accidens** the quantity is changed, *e.g.*, every man is an animal, convertible into, Some animal is man; all Q.C.'s are lawyers, convertible into, Some lawyers are Q.C.'s If, in conversion per accidens, the convertend is true, the converse must be true, *e.g.*, every animal is sentient, converse, something sentient is animal; and, if the converse is false, so too must be the convertend, *e.g.*, something that is irrational is man, converted from, All men are irrational. On the contrary, if the covertend is false, it does not follow that the converse need be false, *e.g.*, All animals are quadrupeds, a false convertend, has a true converse in, some quadrupeds are animals; and, if the converse is true, it cannot be inferred that the convertend is true, as can be seen from the foregoing example. Hence, from the truth of the convertend we can infer the truth of the converse, but not *vice-versâ*; and from the falseness of the converse, the falseness of the convertend, but again not *vice-versâ*.

(4.) It is clear that conversion of propositions implies some process of reasoning capable of being reduced to logical form, *e.g.*, $4=2+2 \therefore 2+2=4$, All planets are heavenly bodies $\therefore$ Some heavenly

bodies are planets; and so we are brought from the **matter** of formal logic to its **form.** Before passing on to it, however, the explanation of the properties of propositions may be simplified by the following table, which is usually given in manuals of logic:

Symbol. **Proposition.**

A. = Universal affirmative.
E. = Universal negative.
I. = Particular affirmative.
O. = Particular negative.



because:

Every man is rational =A.=Universal affirmative.
No man is rational =E.=Universal negative.
This man is rational = I.=Particular affirmative.
This man is not rational=O.=Particular negative.

CHAPTER III.

IX. Form of the act of the agent. X. Definition of the syllogism. XI. Rules of the syllogism.

IX. Form of the "Act of the Agent." In the paragraph on the Division of the "Act of the Agent," it has been shown that the form of the act consists in the internal discourse of the mind which is called reasoning, *i.e.*, in that disposition of ideas and statements, by means of which the intellect attains its end of knowing truth. As the idea, or simple word of the intellect is treated of under the sign **term**, and the statement or "judgment," or complex word of the intellect under the sign **Proposition**; the discourse of the mind or reasoning has for its sign the **syllogism.**

X. Syllogism, Definition. The syllogism is called by Aristotle: "a sentence in which, some things being affirmed, others must necessarily follow from that affirmation." Viewed with relation to its matter, *i.e.*, terms and propositions, the syllogism may be called: a disposition of terms and propositions arranged in such a manner, that from what is known that which is unknown may be deduced. This definition will be found to apply both to deductive and inductive reasoning, and may be stated more simply as: An argument, in which one proposition is gathered or inferred

from two other propositions, by a comparison of the three terms of the argument.

The syllogism then has **three terms** so distributed in three propositions that each one is repeated twice, *e.g.*,

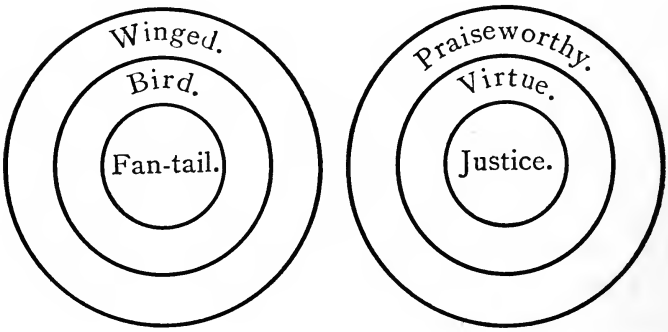
Every bird is winged;
But every fan-tail is a bird:
Therefore every fan-tail is winged.

Again:

All virtue is praiseworthy;
But justice is a virtue;
Therefore justice is praiseworthy.

Of these three terms one is called the comparative or **middle term,** for with it the other two are compared. They are called **extreme terms;** and that one which forms the predicate of the conclusion, or final inferred proposition, is called the greater or **major extreme,** or **major term;** while that which forms the subject of the conclusion is called the **minor extreme** or **minor term.** The reason of their having these names is, that usually in universal affirmative propositions, which, being more perfect than negative ones, supply the names, the predicate has greater extension than the subject, and so the subject has less. As the words are used by logicians, **extension** signifies all the things to which a term applies, while **intension** means the qualities or properties and peculiarities implied in the term, in other words, its definition. Hence the saying that "intension and extension stand in inverse ratios to one another," so that as one increases the other diminishes, *e.g.*, compare ship and steam-ship, pigeon and fan-tail; ship has greater extension than

steam-ship, which has clearly greater intension than ship; and so with pigeon and fan-tail.[1] The remaining term of the syllogism is called the **middle term** because, generally speaking, its extension is less than that of the **major,** and greater than that of the **minor.** To make this clear, we can put our examples into diagram:



Here, winged is the major, fan-tail the minor, and bird the middle term; praiseworthy the major, justice the minor, and virtue the middle term. It is obvious that in these two instances winged and praiseworthy are the terms that have greatest extension, while it is equally evident that fan-tail and justice are the terms with least extension, and so with greatest intension.

The three **propositions** in every syllogism are **(1.)** the **major premiss,** in which the major is compared with the middle term; **(2.)** the **minor premiss,** in which the minor is compared with the middle

[1] See p. 19 for application of universals, and p. 72 *et seq.* for definition.

term; (3.) the **conclusion,** in which the minor is compared with the major term. The two premisses are so called, because they are put forward, or put first, for the purpose of being reasoned about; and they are specified as major and minor because they contain the major and minor terms respectively. The third proposition gathered or deduced from the other two, is called the conclusion, probably because the argument is finished when we have learned what this third or last proposition should be. The whole process can be made clear as follows:

Major Term: Praiseworthy.
Middle Term: Virtue.
Minor Term: Justice.

From these terms we form the collateral syllogism.

Major Premiss: Every virtue is praiseworthy.
Minor Premiss: But justice is a virtue.
Conclusion: Therefore justice is praiseworthy.

Again:

Major Term: Winged.
Middle Term: Bird.
Minor Term: Fan-tail.

From these terms we form the collateral syllogism.

Major Premiss: Every bird is winged.
Minor Premiss: But every fan-tail is a bird.
Conclusion: Therefore every fan-tail has wings.

From what has already been said of the **matter** and **form** of the syllogism, it is evident that a distinction must be made between its **material** and **formal truth.** It is materially true when the propo-

sitions, of which it is formed, are in themselves true: and it is formally true, or correct, if, or rather in so far as its remote matter (terms) are so placed, and its proximate matter (propositions) are so formulated, that the conclusion necessarily follows from the two premisses. Hence an argument or syllogism may be formally true and materially false, and again it may be materially true and formally untrue. But to be perfectly correct or good, it must be both materially and formally true. For instance, the syllogism:

Every beast is irrational;
But man is not a beast:
Therefore man is not irrational,—

is materially true, but formally it is quite untrue or incorrect. From the premisses: Every beast is irrational; but man is not a beast,—I cannot conclude that man is not irrational, for I might draw precisely the same conclusion about a stone, because it is not a beast. On the other hand, the syllogism:

Every substance is material;
But the soul is a substance:
Therefore the soul is material,—

is formally true or correct, but materially untrue because the major premiss is materially untrue.

If the two premisses are materially true, it is obvious that, if the syllogism be formally true, its conclusion must be materially true, because it is **impossible to deduce error from truth.** And, consequently, if the conclusion is materially false, one of the two premisses must be so too, for, unless this were the case, a false conclusion would not be obtained.

Yet, if one of the two premisses is false, it does not necessarily follow that the conclusion will be false. It may be false, it may be true; yet, if true, it is so only per accidens, for its truth is not the result of the argument. And, because in such a case the conclusion can be true per accidens only, it follows that it is so, not in itself, *i.e.*, not as the conclusion, or else the two premisses would be true too, *e.g.*, in the syllogism:

Every virtue is good;
But health is a virtue:
Therefore health is good,—

the conclusion is materially true, and at the same time the minor premiss is materially false. And in the example:

All novels are harmless;
But *Quentin Durward* is a novel:
Therefore *Quentin Durward* is harmless,—

the conclusion is materially true, while the major premiss is materially and most decidedly false. From this general view of the syllogism we pass to

XI. The Laws or Rules according to which the syllogism should be formed, and which concern its **matter** and **form** respectively.

(1.) With regard to the **matter** of syllogisms, the principal rule is that **both premisses should be true,** as has been shown. The extent of that matter is sufficient to prove that the further rules do not come within the scope of purely Formal Logic. We shall meet with them later on in treating of Method and Material Logic.

(2.) The eight rules given by the Scholastics for the **Form** of the Syllogism are based on the two prin-

ciples or canons: (a.) **Dictum de omni, dictum de nullo**=whatever is predicated (*i.e.*, affirmed or denied) of a term taken universally, may be predicated in like manner (*i.e.*, affirmed or denied) of everything contained under it; (b.) **Quæ conveniunt in uno tertio, conveniunt inter se; quæ repugnant in uno tertio, repugnant inter se**=Two things or terms, which agree with one and the same third term, agree with one another; two things or terms, of which one agrees and the other disagrees with one and the same third term, disagree with one another.

Rule I. A syllogism must contain three terms, and not more than three terms; three propositions, and only three propositions. The reason is that syllogising consists in comparing two terms with each other by means of a third term; and, if there were four terms, the argument would consist either of two syllogisms, or of none at all. Suppose the terms to be,—cow, cloven-footed animal, ruminating animal, animal having two stomachs. We may compare the first with the second term, and the third with the fourth; but this will not give a conclusion, unless we have another proposition comparing the second with the third term; and this proposition would give us another syllogism. The reason of the part of rule concerning propositions is that, if there were four propositions, one would be the conclusion, and the other three the premisses; and three premisses will either make no comparison, or they will form two syllogisms. This can easily be made clear by reconsidering the example of the

cows, or the following: oxygen, simple body, carbonic acid gas, compound body.

It is obvious to remark that, whenever any one of the three terms is used in the syllogism, it must have the same sense and the same application; otherwise we should have four terms, *e.g.*, in the syllogism:

All beasts of the earth were created on the sixth day;

But my dog is a beast of the earth:

Therefore my dog was created on the sixth day,—

the middle term, beast of the earth, is applied in the major premiss to the first members of the species, and in the minor to an individual; and thus the syllogism has four terms.

Rule II. There should be nothing in the conclusion which is not in the premisses, *i.e.*, no term should have greater extension in the conclusion than in the premisses. The reason is that what is more universal cannot be contained in what is less universal; and, if the term in the conclusion were taken in a wider meaning than it had in the premisses, it could not in this wider meaning be contained in them, and so could not be drawn from them. Moreover, there would be a fourth term introduced by comparing a part only of the extreme with the middle term, and the whole of it in the conclusion with the other extreme term, *e.g.*:

What I am, you are not;

But I am a man:

Therefore you are not a man,—

where it is clear that man is used in a wider meaning in the conclusion than in the minor premiss.

Again :

All just men are praiseworthy ;

But some Greeks are just men :

Therefore all Greeks are praiseworthy.

Here again, the minor term has greater extension in the conclusion than in the minor premiss ; and there are really four terms in the syllogism, viz., praiseworthy, just men, Greeks used as a particular term, and Greeks used as a universal term.

Rule III. The middle term must be distributed, *i.e.*, taken universally or in its whole extent of meaning, once at least in the premisses. The reason is that, unless we take the whole of the middle term once, the two premisses may refer to different parts of the middle term, so that there will be no true middle term at all, and in fact there will be four terms, *e.g.*, in the syllogism :

Some animal is endowed with reason ;

But the horse is some animal :

Therefore the horse is endowed with reason,—

the middle term, animal, designates the animal that is man in the major premiss, while in the minor it signifies an animal that is a brute, and so in neither case is taken in its full extent of meaning, or universally. And in the syllogism :

Some poet never gives an epithet of colour to a flower ;

But Shakespeare is some poet ;

Therefore Shakespeare never gives an epithet of colour to a flower,—

the middle term, in the major premiss designates Homer ; and in the minor premiss, Shakespeare ; and thus is never taken universally.

Rule IV. The middle term must not appear in the conclusion, either wholly or in part. The reason is that the comparison of subject with predicate, by means of the middle term, is made in the premisses; while the conclusion gives the relation between the subject and predicate themselves, *e.g.*:

Alexander was a general;

But Alexander was little;

Therefore Alexander was a little general,—

offends against this rule. So, too, does:

Alice tumbled down the rabbit-hole in her dream;

But Alice was wide-awake;

Therefore Alice, wide-awake, tumbled down the rabbit-hole in her dream.

Rule V. No Conclusion can be drawn from two negative propositions or premisses. The reason is, that the middle term is then one with which extreme disagrees, and not one with which one extreme agrees and the other disagrees, *e.g.*, from the propositions:

Man is not eternal;

But animals are not eternal,—

no conclusion whatever can follow, neither can we draw one from

Mustard is not a min[illegible]he[illegible];

But charlock is not [illegible] ru[illegible]ineral.

Rule VI. No Co[illegible] sy[illegible]sion can be drawn from two particular propo[illegible]des[illegible]ons. The reason is that, if both are affirmati[illegible]e just[illegible]e middle term in both is taken only in its [illegible]men ar[illegible] extent of meaning, *i.e.*, would be undistrib[illegible]se diar[illegible]which would be contrary to Rule III.; and, [illegible] propositions are not affir-

mative, either the middle term is again undistributed, or else the major or minor term has greater extension in the conclusion than in the premisses,—and this is contrary to Rule II., *e.g.* (two affirmatives) :

Some virtues are pleasing to men ;
But some things that are pleasing to men are displeasing to God :
Therefore some things that are displeasing to God are virtues.

This is wrong, because the middle term, pleasing to like en, is taken universally in neither premiss. And a Sor ault is committed in :

But s e man is living ;
Therefo me man is dead ;

Again (a nega something that is living is dead.

Some men ar ive and affirmative) :
But some soldiers ave :
Therefore some so sc are not brave ;

Here men is taken un rse ldiers are not men.
it is a particular term im iversally in the conclusion, but
manner ; r in the major premiss. In like

Some books are ha a
But *Robinson Crusoe* ll d to understand ;
Therefore *Robinson* syll not hard to understand,

shows a term (book) use ves a *soe* is not a book,—
sion, while in the major niversally in the conclu-
term. some premiss it is a particular

Rule VII. A negati are nev
drawn from two affirma r,—
if both premisses are affi e major premiss designates
both extremes agree with nor premiss, Shakespeare ;
univ lly.

it follows that they must consequently agree with one another. For instance, no amount of ingenuity can draw a negative conclusion from the two affirmative propositions:

All quadrilateral figures are contained by four straight lines;

But a rhombus is a quadrilateral figure.

The conclusion can be nothing else but the affirmative:

Therefore a rhombus is contained by four straight lines.

Rule VIII. If one premiss be negative, the conclusion must be negative; and if one premiss be particular, the conclusion must be particular. The reason of the first part of this rule is, that the remaining premiss is affirmative (according to Rule V.), and hence one of the extremes agrees with the middle term, and the other disagrees with it; and therefore the extremes disagree with one another, *i.e.*, the conclusion is negative. The reason of the second part of the rule is that if the conclusion were universal, while one of the premisses was particular, there would be something in the conclusion that is not in the premisses, which would be a violation of Rule II., and involve a violation of Rule I. by introducing a fourth term. The examples already given of the violation of these rules will make this clear. So, too, will the correct syllogisms:

Every just being is deserving of esteem;
if both are ta[illegible] are just beings:
taken only in its men are deserving of esteem.
would be undistri[illegible]se diameters are unequal, can be
Rule III.; and,

But these two circles have unequal diameters:
Therefore these two circles cannot be equal.

In nearly all manuals of Logic, it is shown that if we try in how many different ways we can make syllogisms with the four kinds of propositions,[2] we can get many good kinds of arguments. These are called the **moods or modes of the syllogism,** and they are divided into **four figures,** each figure being known by the position of the middle term in the premisses; whence **figure** may be defined the position of the middle term in relation to the two extreme terms in the premisses, and **mode** the combination of the quantity and quality in the proposition. Logicians have given names to the different kinds of modes; but, as these modes are merely forms in which the rules of the syllogism can be kept, we shall always be able to tell whether a syllogism is correct if we understand its rules well, and so we can for the present pass by the names of the modes, as of no very great practical importance.

[2] See p. 31.

CHAPTER IV.

XII. Divisions of the syllogism.

XII. Divisions of the Syllogism.—Regular or Complete Syllogisms may be either **Simple** or **Compound**; simple, when they are made of simple propositions; compound, when they are made of compound or composite ones.

(1.) **Simple or Categorical** Syllogisms consist of categorical propositions, sometimes called propositions *de inesse*, from their asserting that the predicate is, or is not, contained in the subject. To these Categorical Syllogisms apply *in toto* the eight rules already explained; while the first canon or principle on which they are based, *i.e.*, Dictum de omni, dictum de nullo, applies immediately to the categorical syllogism. To other syllogisms the dictum applies only ultimately, for this application has, as a rule, to be reached and proved by reducing them to categoricals. The examples of syllogisms already given are all categorical. By re-examining two of them, we shall see how the categorical syllogism depends immediately on the first canon, which serves as a basis for Aristotle's eight rules. Thus, in the example:

All virtue is praiseworthy;
But justice is a virtue:
Therefore justice is praiseworthy,—

virtue is related to justice as genus to species, and hence the term, praiseworthy, must, if it applies to virtue, apply also to justice; because, according to the Dictum de omni, what belongs to the genus necessarily belongs to the subordinate species, and what belongs to the species belongs in like manner to the individuals contained in the species; and therefore we cannot deny of the species what we affirm of the genus; nor can we deny of the individual (as member of the species) what we affirm of the species. The following example will illustrate the application to categoricals of the Dictum de nullo:

No planet is a fixed star;
But Uranus is a planet:
Therefore Uranus is not a fixed star.

Here the term planet indicates species, while the term Uranus designates a member of the species: hence the term, fixed star, if denied of planet, must in consequence be denied of Uranus, because what is opposed to the nature of the species must be opposed to the nature of the individuals belonging to the species; and therefore we cannot affirm of the individual what we deny universally of the species, any more than we can affirm of the species what we deny universally of the genus.

This explanation is merely a development of what has already been said[1] of the Dictum de omni, dictum de nullo, which—if looked at more closely—will be seen to be immediately resolvable into the principle that a thing cannot both be and not be at the same time and under the same conditions, *i.e.*,

[1] P. 38.

into the principle of contradiction, which is the first of all principles. For instance, if we affirm that the genus, virtue, is praiseworthy, and deny that the species, justice, is praiseworthy, we are evidently affirming that something belongs, and at the same time does not belong to the genus, which would be impossible. And we also offend against the principle of contradiction, and consequently enunciate an absurdity, if we affirm of the specific nature of Uranus what we deny of the nature of its species, planet; or if we affirm of the species maidenhair fern what we deny universally of the genus, polypodiacea, a particular order or class of ferns.

(2.) **Compound** syllogisms are either (a.) **hypothetical or conditional,** (b.) **copulative or conjunctive,** (c.) **disjunctive.**

(a.) **Hypothetical** or **conditional,** in which the major premiss at least is a hypothetical proposition, *i.e.*, one consisting of two parts, the **antecedent,** containing the little word "if," and the **consequent,** which tells us what will happen under the supposed circumstances. In the major premiss, therefore, the middle and major terms stand to each other in the relation of **condition** and **conditioned**; and the conditional form of the syllogism itself resulting from that relation, is based upon the principle that nothing can either be or not be without a sufficient reason, *i.e.*, upon the principle of sufficient reason, which is one of the fundamental laws of thought, *e.g.*, in the syllogism:

If Matthew is a man, he is mortal
But Matthew is a man:
Therefore Matthew is mortal,—

the principle, that nothing can be without a sufficient reason, clearly enough underlies the argument that leads to the conclusion. According to this principle, it follows that the truth of the thing conditioned can be inferred from the truth of the condition, while the falseness of the condition can be inferred from the falseness of the thing conditioned. Herein we have the basis of the **rules** of the hypothetical syllogism, which are: **If the antecedent be affirmed, the consequent may be affirmed. If the consequent be denied, the antecedent may be denied.** Hence the thing conditioned must be affirmed in the conclusion from the affirmation of the condition in the minor premiss; or the thing conditioned must be denied in the minor premiss, and consequently the condition must be denied in the conclusion, *e.g.*:

If this boy likes story-books with much morbidness in them and little cheeriness, his taste for reading is probably not healthy;

But this boy does like story-books with much morbidness in them and little cheeriness:

Therefore his taste for reading is probably not healthy.

And in the following example we have the condition denied from the denial of the thing conditioned:

If Heyse's theory of friendship be true, his *Stories of Friendship* must be true to life;

But his *Stories of Friendship* are not true to life:

Therefore his theory of friendship is not true.

The connection between the antecedent and the consequent in the hypothetical proposition is called

the **consequence**; and it is entirely upon this consequence that the truth or falsehood of the hypothetical or conditional proposition depends, and not at all upon the truth or falsehood of the antecedent, or of the consequent, or of both of them, *e.g.*:

If the evolutionists are right, man is only a developed ape.

If we cannot conceive what we cannot imagine, we cannot conceive space to be non-existent.

In these examples both the antecedent and consequent are false, yet the conditional composed of them is true, *i.e.*, one is a true consequence from the other. It is obvious that the truth of this conditional is essential to every good hypothetical syllogism.

It is important not to fall into the error of reversing the terms of the two rules stated, *i.e.*, to affirm the consequent, and then infer that we can affirm the antecedent; or to deny the antecedent, and then infer that we can deny the consequent. The reason of this is that the truth of the condition cannot be inferred from the truth of the thing conditioned, nor the falseness of the thing conditioned from the falseness of the condition, because a given effect or result may have many different causes or reasons. Hence, when we affirm the truth of an effect or result, we cannot infer the truth of the cause or reason assigned to it; and, for the same reason, it does not follow that, because the cause or reason assigned is false, the effect *per se* must necessarily be false, *e.g.*, from the major premiss:

If Jenkins has committed forgery, he is liable to be prosecuted,

I cannot argue either that

Jenkins is liable to be prosecuted;

Therefore he has committed forgery;

Or that

Jenkins has not committed forgery;

Therefore he is not liable to be prosecuted,—

because liability to prosecution has many other causes besides forgery. Moreover, in affirming the antecedent from the consequent, it is evident that the third general rule of the syllogism is broken; for the middle term "liable to be prosecuted" is not distributed in either premiss. In like manner, the middle term "man" is undistributed in the following example:

If he is a man, he is an animal;

But he is an animal;

Therefore he is a man.

Again, to deny the antecedent from the denial of the consequent, is to violate the second general rule of the syllogism, *e.g.*, in the instance already given, "liable to be prosecuted" has greater extension in the conclusion than in the major premiss, and so too has the term "man" in the argument:

If he is a philosopher, he is a man;

But he is not a philosopher;

Therefore he is not a man.

(b.) **Copulative** or **Conjunctive,** in which the major premiss is a copulative proposition; strictly speaking, this major should be a negative copulative. The **rules** of this kind of syllogism are: **The copulative or conjunctive proposition must be true. If one of the things conjoined be affirmed in the minor premiss, the other or others are denied in**

the conclusion. The reason is, that a negative copulative asserts that two or more attributes cannot at the same time be predicated of the same subject, yet without affirming that one of them must necessarily be predicated of it, *e.g.:*

The moon cannot at the same time have a fourfold motion and be motionless;
But the moon has a fourfold motion;
Therefore the moon is not motionless.

Here the negative copulative, while asserting the impossibility of the co-existence of rest and fourfold motion, does not affirm that either one or the other must necessarily be predicated of the moon. In this lies the main difference between the copulative and the disjunctive syllogism, of which we shall treat next. For the same reason, the terms of the second rule cannot be reversed, *i.e.*, we cannot deny one of the conjoined things or terms in the minor premiss, and then affirm the rest in the conclusion; because it will generally happen that the enumeration in the copulative proposition is not a complete one, and therefore that something not contained in that enumeration may be predicated of the subject, *e.g.:*

Peter is not at the same time standing and sitting;
But he is standing;
Therefore he is not sitting:—

Or

But he is sitting;
Therefore he is not standing.

But we cannot argue from the same major: he is not standing; therefore he is sitting; for he might

be kneeling, or lying down, or in some other position. Again, from the major:

No man can serve God and mammon,

It does not follow that, because

Many do not serve mammon;

Therefore they serve God,

For they may have given themselves over to the service of some passion other than the love of money. St. Francis Xavier, for instance, before his conversion by St. Ignatius, bid fair to become the slave of love of human glory; and no one will say that it was love of money that held St. Augustine and De Rancé and Father Hermann enthralled before grace triumphed in their hearts. Of course, if the enumeration in the copulative proposition were quite complete, the transposition of the rule would be correct, *e.g.*:

It cannot be at the same time day and night:

But it is not day;

Therefore it is night.

For it must be either one or the other.

Though differing in form from the disjunctive syllogism, the conjunctive syllogism is generally resolvable into it, and always closely allied to it, for both are based alike on the same fundamental law of thought, viz., on what is called the "principle of the excluded third," *i.e.*, that there is no mean between two contradictories; for, if a thing cannot both be and not be at the same time and under the same conditions, it necessarily follows that it must either be or not be. Being and not being absolutely exclude one another: a mean between those extremes is inconceivable. And it is the same with our minds:

they must either affirm or deny what is predicated of the subject: between affirmation and denial there is no mean. For instance, the conjunctive proposition, "No one can at the same time sing and play the flute," leaves no middle course open between affirmation and denial; neither does the disjunctive proposition into which it can be resolved. He either sings or plays the flute, which may be further simplified into,—He either sings or he does not sing; he either plays the flute or he does not play the flute. Thus, as the principle of contradiction is the principle of affirmation and denial, the principle of the excluded third asserts that between affirmation and denial there is no middle course.

(c.) **Disjunctive**, in which the major premiss is a disjunctive proposition, *i.e.*, one which has several terms joined by the word "or," or by some other disjunctive particle, and in which the relation between the major and middle term in the major premiss is one of opposition. As we have seen, the form of the disjunctive is like that of the conjunctive syllogism, determined by the principle of the excluded third, which is the basis of the chief **rule** of the disjunctive sollogism, which is: **If one or more alternatives be denied, the rest may be affirmed.** Hence the disjunctive major must be true, *i.e.*, one, or some of its members must be true, or the disjunction would be false; and there must be opposition between the members: the distribution or enumeration of members must be adequate, *i.e.*, it should include all members that might be enumerated; and no member should include another member. The application of the rule to syllogisms

in which the disjunctive major has only two members, is that one member will be denied in the minor premiss, and the other affirmed in the conclusion. In syllogisms, in which the disjunctive major premiss has more than two members, and only one is denied in the minor premiss, the rest will be affirmed in the conclusion, which thus becomes a copulative or conjunctive proposition. As instances of these two applications, we may take:

The sun either moves or is stationary;
But it is not stationary;
Therefore it moves.

Titian's "Noli me tangere" is either in the Manfrini Palace, Venice, or in the National Gallery; But it is not in the Manfrini Palace, Venice;
Therefore it is in the National Gallery.

A known planet must either be Mercury, or Venus, or the Earth, or Mars, or Jupiter, or Saturn, or Uranus, or Neptune, or one of the planetoids.
But it is not one of the planetoids; Therefore it must be either Mercury, or Venus, or the Earth, or Mars, or Jupiter, or Saturn, or Uranus, or Neptune.

This four-sided figure must be either a square, an oblong, a rhombus, a rhomboid, or a trapezium;
But it is neither a square nor an oblong;
Therefore it must be either a rhombus, a rhomboid, or a trapezium.

It is sometimes said that the terms of the rule of the disjunctive syllogism may be reversed, and so

that: **If one or more alternatives be affirmed, the rest may be denied**; hence that when the minor premiss affirms one or more members, the rest will be denied in the conclusion. This must necessarily be the case where there are only two members or alternatives in the major premiss: but it is possible, when there are many members in the major premiss, that we may affirm one in the minor, and yet not be able to deny the rest in the conclusion, *e.g.*, a magistrate is either a justice of the peace, or a mayor, or a stipendiary magistrate; but it does not follow that one who is a justice of the peace is not a mayor. Yet it is obvious that the disjunction is true, and the enumeration adequate in the example given. So is it likewise when we say, Tilly was defeated either at Wimpfen, or Höchst, or Lutter, or Breitenfeld, or the Lech, or some other battle in which he commanded; but we cannot conclude that because he was defeated at Breitenfeld, he was not defeated in any other battle, for Gustavus Adolphus gained the day at the battle of the Lech. We see then that we can only rightly affirm one alternative, and then deny the others, if there be such a difference between them that they could not be true at the same time, *e.g.*, if I am examining the planet Jupiter through a telescope, and I see his moon Ganymede, I can say,—Because this moon is Ganymede, it can be neither Io, Europa, nor Callisto. Or I am examining a class of seven small boys; a bright little fellow attracts my attention; I look at the class-list and see that this boy must be either Sinbad, or Selim, or Aladdin, or Crusoe, or Merton, or Alfgar, or Tempeston; the teacher at my side whispers

that it is Alfgar, thus supplying a minor premiss; whereupon, supposing the enumeration in my major, the class-list, to be adequate, I am quite justified in concluding that my young examinee is neither Sinbad, nor Selim, nor Aladdin, nor Crusoe, nor Merton, nor Tempeston.

From what has been said of the disjunctive syllogism, it is clear that it does not obey all the general rules of the syllogism, *e.g.*, in our last examples a negative conclusion is drawn from two affirmatives, which is contrary to Rule VII.; and, in the first examples of the disjunctive syllogism, an affirmative conclusion follows from premisses, of of which one is negative, which is against Rule VIII. This rule is also broken in conjunctive or copulative syllogisms when their conclusion is affirmative:[5]

(3.) The general **rule** for **testing the validity of compound,** *i.e.*, hypothetical, conjunctive, and disjunctive **syllogisms,** is **to reduce them to the simple** or categorical syllogism, which is the means of applying to them the *Dictum de omni, dictum de nullo,* to which they must be conformed if they are valid, or have a true illation, and which, as we have seen, applies immediately to all categorical syllogisms. This reduction need not usually be difficult; for the two extreme terms are found in the conclusion, and the middle term is seen in the premiss. When we have our three terms, we can readily form them into a categorical syllogism, *e.g.*, the hypothetical:

If God is just, He will reward virtue;
But He is just;
Therefore He will reward virtue;

5 See xii. 2. b.

can be reduced to the categorical:

A just being will reward virtue;
But God is a just being;
Therefore God will reward virtue.

CHAPTER V.

XIII. Incomplete and extended syllogisms.

XIII. Incomplete and **Extended Syllogisms.** So far we have been considering complete Syllogisms, *i.e.*, those which are stated at full length, and end with the conclusion drawn from two premisses. But, usually speaking, only one premiss is stated, and a reader can without difficulty judge, from its union with the conclusion, what the suppressed premiss should be. Such syllogisms are called **Incomplete.** Again it often happens that a conclusion is not reached by one syllogism, but by a series of syllogisms, each of which is in some way dependent on the one going before it; and these syllogisms are known as **Extended.** By some logicians those two classes of syllogisms are called "forms of argument akin to the syllogism," as they are not in strict syllogistic form.

(1.) Under **Incomplete Syllogisms** we have—

(a.) The **Enthymeme,** in which one of the two premisses is suppressed, but the conclusion is introduced by "therefore," "hence," or some equivalent word. Thus we may call the Enthymeme an argument in which the conclusion is deduced imme-

diately from one of the premisses without a formal syllogism, *e.g.*,

The human soul is spiritual;

Therefore it is immortal.

Here the major premiss, what is spiritual is immortal, is evidently understood. And, in arguing that

The radii of the same circle are equal to one another,

Therefore these lines are equal to one another,

the conclusion is at once deduced from the major premiss, the minor, These lines are radii of the same circle, being suppressed.

(b) The **Contracted Syllogism,**—which is really a causal proposition,[1]—in which one premiss is suppressed, and the other is united to the conclusion by "because," "since," "for," or some equivalent word, *e.g.* Man thinks because he is rational, is a contraction of the syllogism:

Rational beings think;

Man is a rational being;

Therefore man thinks.

And, when we say, The thermometer is below 32° Fahrenheit because it is freezing, we are reasoning from the suppressed major premiss, whenever it freezes the thermometer is at or below 32° Fahrenheit.

(2.) The **Extended Syllogism** may be either a

(a.) **Polysyllogism,** in which two or more complete syllogisms are so united in a series that the conclusion of one forms a premiss (usually the first premiss) of that one which follows it, *e.g.*, the co[illegible]te syllogisms,

[1] See p. 23.

1. An infinitely perfect being is infinitely just;
   But God is an infinitely perfect Being;
   Therefore God is infinitely just.
2. He who is infinitely just, punishes evil;
   But God is infinitely just;
   Therefore God punishes evil.
3. God punishes evil;
   But calumny is evil;
   Therefore God punishes calumny.

May be thrown into a polysyllogism thus:

Major. An infinitely perfect being is infinitely just;

Minor. But God is an infinitely perfect Being;

Conclu. of 1, *and Minor of* 2. Therefore God is infinitely just.

Major. He who is infinitely just punishes evil:

Conclu. of 2, *and Minor of* 3. Therefore God punishes evil.

Major. But calumny is evil;

Conclu. Therefore God punishes calumny.

The polysyllogism is generally used either when the train of reasoning is evident, or to shorten a prolix argument. When the single syllogism constituting the series are all of the same kind (*i.e.*, when they are all categorical, or all hypothetical), we have a "pure" polysyllogism; otherwise the polysyllogism is known in contradistinction, as "mixed." The syllogistic series, out of which an actual polysyllogism may be formed, or into which it may be resolved, is sometimes called the "perfect polysyllogism," because it is in perfect syllogistic form; while the polysyllogism formed from it is designated a "contracted polysyllogism," because in each link of the

argument one premiss is really suppressed. This may be illustrated by the following syllogistic series and the polysyllogism to which it is reduced:

1. That which is composed of parts is limited;
   But matter is composed of parts;
   Therefore matter is limited.
2. That which is limited is subject to change;
   But matter is limited;
   Therefore matter is subject to change.
3. That which is subject to change supposes succession;
   But matter is subject to change;
   Therefore matter supposes succession.
4. That which supposes succession must have had a beginning;
   But matter supposes succession;
   Therefore matter must have had a beginning.
5. That which must have had a beginning cannot be eternal;
   But matter must have had a beginning;
   Therefore matter cannot be eternal.

From this we get the polysyllogism.

Major. That which is composed of parts is limited;

Minor. But matter is composed of parts;

Conclu. of 1, *and Minor of* 2. Therefore matter is limited.

Major. That which is limited is subject to change;

Conclu. of 2, *and Minor of* 3. Therefore matter is subject to change.

Major. That which is subject to change, supposes succession;

Conclu. of 3, *and Minor of* 4. Therefore matter supposes succession.

Major. That which supposes succession must have had a beginning:

Conclu. of 4, *and Minor of* 5. Therefore matter must have had a beginning.

Major. That which must have had a beginning, cannot be eternal;

Conclu. Therefore matter cannot be eternal.

(b.) **Epichirema,** where the reason of the union of the subject and predicate is indicated in one or both of the premisses. Such a premiss thus becomes a causal proposition or contracted syllogism, and hence the Epichirema may be resolved into as many syllogisms as it contains causal propositions *plus* the main syllogism, *e.g.*,

Every spiritual being is incorruptible, because it has no parts and does not depend on matter;

But the human soul is a spiritual being, for if it were not so, it would be incapable of thought;

Hence the human soul is incorruptible.

It is obvious that this example is resolvable into many syllogisms. First, we take the main argument:

Every spiritual being is incorruptible;

But the human soul is a spiritual being;

Therefore the human soul is incorruptible.

In proof of the major we have—

That which has no parts is incorruptible;

But all spiritual beings have no parts;

Therefore all spiritual beings are incorruptible.

That which does not depend on matter is incorruptible;

But spiritual beings do not depend on matter;
Therefore spiritual beings are incorruptible.

And in proof of the minor—

If the human soul is capable of thought, it must be a spiritual being;
But the human soul is capable of thought;
Therefore the human soul must be a spiritual being.

This may be reduced to a categorical by changing the major premiss into—

Whatever is capable of thought, must be a spiritual being.

It must now be clear that the Epichirema is not a single argument, but a combination of many arguments. It is generally used in elucidating obscure questions, or in addressing readers or hearers who are known to be opposed to the conclusion.

(c.) **Sorites,** in which the predicate of the first proposition is the subject of the second; the predicate of the second, the subject of the third; and so on till the conclusion, which is formed of the subject of the first and the predicate of the last. Hence there will be as many syllogisms in the sorites as there are propositions between the first premiss and the conclusion, which is reached through a series of major premisses, the first premiss being the only minor expressed in the sorites. Thus, no proposition except the first should be particular; and if that be particular, the conclusion must be so also; and no proposition except the last may be negative, and then the conclusion will be negative, *e.g.*,

God is a necessary Being;
A necessary being is a perfect being;
A perfect being is an omnipotent being;
An omnipotent being can do all things;
Therefore God can do all things.

Here we have three syllogisms formed of the—

Major Term: Do all things;
Middle Terms: A necessary being; A perfect being; An omnipotent being;
Minor Term: God.

And the sorites formed from them differs from the polysyllogism only in the suppression of the immediate conclusions, which thus must in the sorites, as in the polysyllogism, form one of the premisses of the next syllogism. Should they not do so, the sorites will be formally false; and hence its formal truth may be proved by reducing it to a series of simple syllogisms. Its material truth will be destroyed, or at all events injured, by introducing into the series of major premisses either false or ambiguous terms; for this would be either to break or to weaken the chain of the argument, and, by rendering the conclusion unwarrantable, to destroy its value.

The sorites may be either categorical, *i.e.*, formed of categorical propositions, as in the example given; or hypothetical, *i.e.*, formed by hypothetical propositions, *e.g.*,

If Timour is a man, he is a rational animal;
If he is a rational animal, he is a sensitive living being;
If he is a sensitive living being, he is an animate body;

If he is an animate body, he is a composite substance;

Therefore, if Timour is a man, he is a composite substance.

Or else: Therefore, if he is not a composite substance, he is not a man.

Or else: But Timour is a man;

Therefore he is a composite substance.

This last way of putting the conclusion shows that in the hypothetises sorites, the minor premiss may sometimes immediately precede the conclusion, instead of heading the series of propositions.

(d.) **Dilemma** (or **Trilemma, Tetralemma,** &c., according to the number of its disjunctive members), in which the major premiss is a disjunctive proposition, from each member of which the same consequent is drawn hypothetically in the hypothetical minor premiss (which thus has as many members as there are parts in the disjunction), while the conclusion infers categorically the truth of the common consequent. In other words, the disjunctive major is formed of members opposed to one another in such a manner, that, if one be admitted, the proposition under proof, must be established, *e.g.*, Tertullian says in his *Apology:*

The command of the Emperor, that the Christians are not to be sought out, and that only those are to be punished who are denounced as such, is unjust; because—

The Christians are either guilty or they are innocent;

If they are guilty, the command is unjust, because if guilty they ought to be denounced;

If they are innocent the command is unjust, because if innocent they ought not to be punished;

Therefore, whether the Christians are innocent or guilty, still the command is unjust.

Again, if some presumptuous speculator, calling in question the judgment of the Most High, were to ask, Who on earth knows what becomes of the Malays or Hindoos after death? we may propose to him the unanswerable dilemma:

If, on the one hand, those poor people cannot help breaking the Ten Commandments, as some persons say they cannot, for want of better knowledge, then, depend upon it, they do not go to Hell;

If, on the other hand, they do go to Hell, they go there for doing that which they well knew was wicked, and which they well were able to refrain from doing;

Either way, the justice of the Most High is above reproach.

Such arguments are often called "horned syllogisms," because if any member of the disjunction be admitted, whoever denies the conclusion must be beaten: hence the expression "choosing between the horns of a dilemma."

In all these arguments it is necessary—

(α.) that the disjunction in the major premiss should be adequate or complete;

(β.) that the consequence in the minor premiss should be true, and a necessary conclusion from the disjunction;

(γ.) that the dilemma or conclusion cannot be turned against the arguer by an adversary.

Against the first and second of these rules, Socrates errs when he says:

In death, sensation is entirely lost, as in sleep, or the soul passes to a happier land;

If the first is the case, I shall calmly repose;

If the second is the case, how much more happily shall I live with Orpheus, Ulysses, and all the other celebrities;

Hence in either case it would be expedient or better to die; and therefore, whether sensation is lost as in sleep, or the soul passes to a happier land, it is still expedient or better to die.

Here the disjunction is obviously incomplete, for the possibility of eternal misery is unmentioned; and the consequence drawn is not a necessary one.

Against the third rule the mother offended, who thus urged her son not to undertake any office in the State:

Either you will fulfil it ill, or you will fulfil it well;

If well, you will displease men;

If ill, you will displease God;

Therefore, whether you fulfil it well or ill, you will always displease someone.

To this the son readily retorted:

I shall fulfil the office either ill, or well;

If well, I shall please God;

If ill, I shall please men;

Therefore, whether I fulfil it well or ill, I shall always please someone.

Like every other form of the extended syllogism, the dilemma is really a compendium of syllogisms, of which it contains at least as many as there are members in the disjunctive major premiss. It has sometimes been called the deadly weapon of reasoning; for, when all other arguments fail to convince, a good dilemma being unanswerable, must necessarily at all events close the discussion. To prove whether or not a dilemma is good, we have only to resolve it into its component syllogisms; *e.g.*, suppose that a Frenchman, taken prisoner in China, were offered his life and liberty on the condition that he passed satisfactorily an examination in Chinese theology, after two days' study of an appointed text-book in solitary confinement, he would probably resign himself to failure and captivity, in face of some such argument as the following dilemma, or rather trilemma:

The questions will be set in Chinese theology, either from the text, or from some other book, or from some source of traditional information;

If they are set from the text I shall fail, because I can no more understand the text than I can understand the language of the Potowatomies;

If they are set from some other book, I shall fail, because I know no more of Chinese theology than I have read in the text which I cannot understand;

If they are set from some source of traditional information, I shall fail, because I do not know a single Chinese tradition.

Therefore, whether they are set from the text, or from some other book, or from some source of traditional information, still I shall fail.

This example may be reduced to many simple syllogisms. To begin with the simplest:

The questions will be set in Chinese theology;

I cannot answer what will be set in Chinese theology;

Therefore I cannot answer the questions; in other words, I shall fail.

Upon this we can build three more simple syllogisms, according to the number of members in the disjunction. But each member of the hypothetical minor premiss consists of a causal proposition, or contracted syllogism; and, by expanding each of these, we get three more *bonâ fide* syllogisms: so that our dilemma is reducible to at least seven distinct syllogisms.

CHAPTER VI.

XIV. The act of the agent in relation to its end. XV. Method. XVI. Division of method.

XIV. So far, in considering the "act of the agent" of logic, we have been concerned with the laws on which depends the formal truth, or accuracy of thought, considered purely in itself as thought, *i.e.*, with logical truth, which consists in the correspondence between the thought and the formal laws of thought." But as the end of reasoning, and therefore of logic, consists in the material truth of thought and in the attainment of certainty, we must next look at the order which should be followed if we would attain this end, or—as we may put it—at the necessary link between the act of the agent and the end of that act, or at the act of the agent in relation to its end. This is done in what is called method, and its right to a prominent place in logic can very soon be vindicated. We have seen that Suarez calls it "the proper office of logic to give the means of acquiring true science." Now the means of acquiring true science can be nothing else than the way that leads to it, and in that way, as in every other, there is a starting point, a road to be followed, and a destination. The starting-point is our own mind, or more immediately those mental processes we have been

examining as "the act of the agent;" the road to be followed, if we would reach the destination we have in view, is method; and the necessity of method bears, consequently, an exact proportion to the necessity of its end.

XV. Method then may be defined: the order or process which should be followed by the mind in order to attain its proposed end, *i.e.*, certainty and truth. Hence, in method thought is no longer considered purely for its own sake, but in its relation to objective truth, though we have not yet to do with the matter of the thought which corresponds to the objective truth. Besides telling us the order to be observed by the mind in seeking truth, method likewise teaches us the laws on which the formal accuracy of this order depends in each of its divisions.

XVI. Division of method. In investigating an objective truth, and making it cognizable to the intellect, three things are necessary:

(1.) We must ascertain what the thing really is, which forms the subject of our inquiry; and this is done by **Definition:**

(2.) We must distinguish the parts which constitute the whole of the thing; and in this we have the work of **Division:**

(3.) We have to establish the truth of our assertion by proofs, *i.e.*, to verify or prove the objective truth of the subject of our enquiry; and here we have the function of **Argument,** or more closely of **Demonstration.** It is needless to explain how these three processes correspond to their signs, which we have been studying as the matter and

form of Formal logic, and to the mental processes of which those signs are an interpretation.

(4.) Lastly, Methods treat of **Science** or **Knowledge,** or—more exactly—**Scientific Knowledge,** as the outcome or result of Definition, Division, and Argument or Demonstration, which three processes will be found to comprise the whole operation of the mind in its investigation of truth. Then, as objective truth in its totality is not merely a conglomeration of many separate truths, but as all objective truths form together one inter-connected, comprehensive whole, the mind does not stop at the acquirement of particular truths piecemeal, so to say, but passes on to combine them into a higher or scientific whole; and so method has to deal with the order which should be followed in this combination. Besides all this, it has to determine the laws or rules upon which depends the formal accuracy of this fourfold process. Thus, in the means between the "act of the agent" and its end, we have to consider Definition, Division, Argument or Demonstration, and scientific knowledge as such.

CHAPTER 7.

XVII. Definition. XVIII. Rules for definition.

XVII. Definition. To define is, according to its derivation, to circumscribe within limits; and so, to define a thing is to circumscribe it within limits in such a manner that it may stand out clearly and distinctly from all other things; whence definition may be called a clear exposition or explanation of that which is the subject of investigation, or a precise statement of the qualities which are just sufficient to mark out a thing or class. Exposition or explanation may be taken as a sort of generic term including the various kinds of definition, which all fall within its extension, while severally exceeding it in intension. Now, we can explain either words or things, and thus definition is primarily either nominal or real.

(1.) **Nominal,** *i.e.*, of words, of which it explains (a) either the etymology or derivation, *e.g.*, philosophy=love of wisdom, method=way following after, sorites=heaped up; (b) or the ordinary use in common parlance, *e.g.*, by the name sun we understand the star which is the centre of our system, and regulates our days and seasons, by the name winter we understand the coldest months of the year; (c) or the use in particular cases, *e.g.*, *Mercury* as the name of some particular vessel, the

Spectator as the name of a leading literary paper, *Vice-versâ* the name of Anstey's famous story.

(2.) **Real,** *i.e.*, a definition which explains, not the word, but the thing itself implied by the word, and which shows what the thing is in answer to the question, What is it? thus clearly distinguishing it from all things else. A real definition may be either descriptive, genetic, or essential.

(a) **Descriptive,** *i.e*, one which answers the question **quid sit** by painting a clear picture of the thing, and distinguishes it from all others by explaining or depicting its qualities whether proper or accidental, but does not penetrate to and show its essence, *e.g.*, man is a civil, political, religious animal endowed with speech; James is a strong, tall, dark-haired, athletic-looking fellow; in *Troilus and Cressida* Shakespeare thus paints for us the youth of Greece, "The Grecian youths are full of quality; they're loving, well composed, with gifts of nature flowing, and swelling o'er with arts and exercise;" and Virgil gives the following descriptive definition of Polyphemus:

Monstrum horrendum, informe, ingens, cui lumen ademptum,
Trunca manum pinus regit, et vestigia firmat.

Clearly enough, these are no definitions, properly so called; they do not go beyond description; but of things whose essence is either not known or has not yet been formulated, description is all that we can give, and in other cases it prepares the way for exact definition. Descriptive is often called Physical Definition because the definitions of Physical Science do not generally express the essence,

but are a synthesis of the accidents which are properties of a class. Such, for instance, would be to define sodium as a silver-white metal, soft at ordinary temperatures, melting at 95·6°, volatilizing, and yielding a colourless vapour below a red heat; its combining weight being 23, and its specific gravity 0·97; or to call liquefaction, the passage from a solid to a liquid state; and sublimation, the conversion of a solid into a gas.

(b.) **Genetic,** *i.e.*, a definition which explains a thing by describing its origin, or the way it is produced, or how it is formed from its components, *e.g.*, an eclipse of the moon is occasioned by the earth passing between the sun and the moon; a circle is made by drawing from a given point a circumscribing line, each part of which is at precisely the same distance from the given point; manganese monoxide is a greenish powder obtained by heating the carbonate in absence of air. Though not strictly speaking definitions, because they do not show the essence of the thing, these genetic definitions have nevertheless a better claim to the title than have those of the simply descriptive class, inasmuch as they usually show more clearly what the thing is, and distinguish it from all things else, and sometimes directly lead up to essential definition.

(a.) **Essential,** *i.e.*, a definition which explains a thing by showing what are the principles that constitute its essence; whence it may be defined, an exposition of the constituents of the essence of the thing. This is *bonâ-fide* definition; for by giving the essence, *i.e.*, "that which makes the thing what it is," it answers the question *quid sit* in the

only satisfactory way possible. Hence, an essential definition is the only kind of real definition, in the strict or exact sense of the term. But the essence of the thing is comprehended in the idea or concept representative of it; and therefore from a subjective point of view essential definition may be called conceptual definition, or an exposition of the essential matter of the idea or concept. The reason is obvious. Such a definition expresses in the first instance the essential constituents which form the concept, and consequently formulates *eo ipso* the essence of the thing represented by the concept.

It may be useful to note parenthetically that, as the same object may be viewed under various subjective aspects, two or more essential definitions of the same thing may be equally good, yet not identical in form. For instance, from a metaphysical point of view in which my definition is a synthesis of the matter and form of the object, I should define man as a being formed of an organic body and an intellectual soul; the body being the matter, *i.e.*, that element which is in itself indeterminate but is capable of receiving determination from another, and the soul being the form, *i.e.*, that which determines the indeterminate matter, or in other words makes it what it is. From a logical point of view, in which my definition is a synthesis of the genus and differentia which constitute the species, I should define man as a rational animal, or still more logically as an animal rational. Both these definitions are an exposition of the essence of the thing represented by the concept. The difference between them lies

in this, that the metaphysical definition regards the constituents of the essence, *i.e.*, soul and body, as possibly separable, though actually inseparable; whereas in the logical definition the constituents of the essence, *i.e.*, the animal and rational elements are separable only in thought and not in fact, because the intellectual soul is the principle of both.

Now, as every logical definition expresses the components of the concept, and as these components consist of the genus and differentia constituting the species of the object, it is clear that the essential components of every logical definition must be the proximate genus and ultimate differentia of the matter of definition, and nothing else. The *proximate* genus, be it remembered, not any genus higher up in the scale. To define man, for instance, as a rational substance, or a bear as a plantigrade body, would not be to express the essence, and so would not be an essential definition, though cases of this kind might sometimes pass for description. But, by showing what the thing defined has in common with some other things, viz., its proximate genus, which implicitly contains every superior genus up to the *genus supremum*, and what differentiates it, viz., the species, an essential definition forms a sort of compendium of all the knowledge that can be gained concerning the thing as such.

Although every essential definition is really the last link in a chain of definitions, inasmuch as we can mount up through the definition of a series of generic terms to the *genus supremum*, yet the fact of there being a *genus supremum* shows that we cannot

go on defining by genus and species *in infinitum.* Why? Because the defining term in every defining proposition, *i.e.*, the predicate expressing the proximate genus and differentia, is representative of a composite concept corresponding to the composite essence of the thing defined. But, ascending in the scale of genera, we come at last to a genus which includes all the sub-genera, and cannot itself be differentiated. This is the *genus supremum;* and, if it cannot be differentiated, the concept corresponding to it cannot be composite; if not composite it must be simple; and hence the simple concept must be the limit of logical definition. For instance, if I define man as a rational animal, animal as a sensitive living being, living being as an animate body, body as a composite substance, I am stayed from further definition by my simple concept of substance, *i.e.*, being which exists in itself, as opposed to accident, *i.e.*, being which necessarily inheres in some other. These two genera, substance and accident, divide all being, which as transcendental includes and goes beyond or transcends everything. Hence, of being, substance and accident, and of some other things which do not enter into the province of logic, it is impossible to give any definition; but it need hardly be said that they can be to some extent explained and described; while no one will question that explanation of the indefinable is immeasurably more difficult than definition of the composite.

As definition is limited from above by substance and accident as all-embracing genera, so is it limited from below by individuals and single instances of

fact. Again, why? Because the concept representative of the species must be universal; if universal, it can be applied to many things; if applicable to many things, it cannot be confined to any one thing. Further, the species cannot become a subgenus when the concept excludes the addition of any determining differentia, as, *e.g.*, in man: a Zulu is a rational animal, so is an Englishman; different as they are, the difference is not essential: so in that category it is evident that definition cannot take cognizance of individuals. Here, however, description comes in to perfect the work of definition, and to distinguish the objects of definition by depicting their properties and accidents, *e.g.*, the battles of Cannae, Platea, and Waterloo were all alike in being battles; but, waiving for the moment the question of causes and effects, description will tell us how they differed.

XVIII. Rules which ensure the **formal accuracy of definitions.** A definition should be:

(1.) **Adequate and exclusive**; in other words, it must include all, and only, those objects which it can define: hence it should be neither more nor less comprehensive than the thing defined, *e.g.*, to define Logic as "the science of the laws of formal thought," would be an insufficient definition, for it would not include the whole of Logic; and to define meteorology as the science of storms would be to exclude many of the most important things taught by meteorology. On the other hand, to define planet as a heavenly body, would be to give too wide a definition, for there are other heavenly bodies besides planets; and a like fault would be committed

in defining fortitude as a good quality, for good is far from the ultimate differentia.

(2.) **A thing must not be defined by its own name,** nor by any word **derived from or equivalent** to its name. This would be to induce a vicious circle, of which more anon. Logic, for instance, must not be called "the science of the laws of Logic, or of logical laws;" nor can arithmetic be defined as "the science of arithmetical processes."

(3.) A definition must be **clearer than the thing defined.** Otherwise it would not answer its end, which is the elucidation of the thing. Hence we should not in definitions make use of obscure, double meaning, or merely metaphorical expressions, *e.g.*, when Burke calls law "beneficence acting by rule," he uses a very true metaphorical expression, but we must not mistake it for a definition; and the same may be said of the well known aphorism of Novalis, that "character is a completely fashioned will."

The quality of clearness is, however, relative, for we cannot expect philosophical definitions to be self-evident to uneducated minds; and it would be a mistake to reject good definitions because they are not apparently easy of comprehension, and to fix instead upon others which, though possessing a fallacious clearness, are neither philosophical nor true.

(4.) A definition **should not be negative.** For a merely negative definition does not explain what the thing is, but what it is not; and hence must always have greater extension than the thing defined, *e.g.*, we cannot define man by saying he is not a pure spirit, for many things besides man are not pure spirits;

nor can we define a beast by saying that it is not a rational animal, for this is true of all things excepting man. Only when its contrary has been positively defined, or when we are leading up to such definition, may we define a thing negatively; and the negative definition has merely this value, either that by its means the way is prepared for positive definition, or that the positive definition is more strikingly told out. As an instance we may name the passage in Cardinal Newman's *University Lectures*, where he answers his own question, "What is Theology?" by saying "what it is not," before passing on to tell us "what it is." Thus, too, after defining "compound or composite," as that which is formed of parts, I can at once define "simple" as that which is not formed of parts.

(5.) A definition should **be short and exact, or distinct**; it should avoid prolixity, and express the genus and species in as few words as possible, as far as this can be done without detriment to its distinctness. Definitions formulated in long involved sentences should always be avoided; it will usually be found that inexactitude, obscurity, and prolixity involve violations of rules other than that which draws attention to distinctness and precision.

CHAPTER VIII.

XIX. Division. XX. Rules for division.

XIX. Division, as its name implies, is the distribution of a whole into its various actual or conceivable parts, regarded from a given point of view. It is, as we have seen, presupposed in every definition, as the necessary analysis preceding synthesis; and its value has been strikingly estimated by Plato, who says,[1] "If I were to meet with a leader who knew how to divide rightly, I would follow his footsteps as those of a God." In every division, then, we have (1.) **a whole to be divided,** (2.) a given point of view from which the whole is considered in its division, *i.e.*, **a ground or basis for the division,** (3.) parts into which the whole is divided, *i.e.*, **members of the division.**

(1.) **The whole** to be divided may be either actual, potential, or moral.

(a.) **actual,** *i.e.*, one whose component parts form its substance or nature; man, *e.g.*, is an actual whole as composed of body and soul, which are the components of his nature. Partition is the name usually given to the division of an actual whole; it may be either physical, metaphysical, or logical. A whole is called **physical** when its parts are separable, as are, for instance, body and soul;

[1] *In Phæd.*

metaphysical, when the parts are really distinct, yet not separable, *e.g.*, the soul of man which possesses powers and faculties really distinct from each other, but inseparable either from the soul or from each other; **logical** when a thought, which is a simple act, is the matter of analysis, *e.g.*, a statement or judgment as composed of its matter and form, *i.e.*, two terms and a copula; or a composite concept, or the subject of a discourse or treatise. As thought is a simple act and therefore indivisible, we do not, of course, in a logical whole, attempt to regard "parts" of thought, but the signs by means of which we reflect upon our thought, and which our minds apprehend as its "parts," in order to make such reflection possible. In other words, we think of thought, which is itself simple, as composite because, if we go below the most surfacial of surfaces, we cannot in our present imperfect state conceive of a simple whole. In Heaven all this will be very different.

(b.) **potential,** *i.e.*, a whole whose parts are not the components of its substance or nature, but of its extension; and so are comprised in the whole, not actually but potentially. Every universal term is therefore a potential whole, in so far as it comprises as a whole a number of members, to which it can be applied. Thus every genus is a potential whole with regard to its species, and every species with respect to the individuals comprised under it; *e.g.*, animal is a potential whole comprising man, beasts, birds, fishes, &c. The division of potential wholes is division in the exact sense of the term, in contradistinction to partition and distribution, and is

formed according to the parts of the extension.

(c.) **moral,** *i.e.*, a whole whose component parts are independent beings formed by some external principle into a collective unity, or rather union, *e.g.*, an army is a moral whole, for though the soldiers are united as members of one body, this union has only a collective character. As distinguished from the partition of actual, and the division of potential wholes, the division of moral wholes is termed distribution. The division of an army into brigades, regiments, battalions, &c., is a distribution; so is the division of the college into schools, of a congregation into various establishments.

From considering the chief kinds of wholes, we now pass to

(2.) **The basis of division.** This may be either internal or external. It is internal when we consider the inner specific nature; external when we make our division from a merely outward aspect of the properties of the whole, *e.g.*, in dividing living being into plants, animals, and men, and in dividing the cardinal virtue of fortitude into active and passive fortitude, the basis of division is internal or intrinsic; but it is altogether external in the Linnaean system of botany, and in the classification of a set of boys according to height. Moreover, whatever kind of a whole we may have, it is possible that it may be regarded from many points of view; and hence there may be many and very different bases for the division of the same whole; and thus we get many divisions which are not interconnected, or subordinate one to the other, but are strictly co-

ordinate and independent. Illustrations of this may be found in the division of terms and propositions (*q.v.*), and they are not difficult to meet with elsewhere. If I am writing an account of the Thirty Years' War, say, I may divide the period arbitrarily according to time into three decades, or I may mark it off according to certain distinctive notes into the Palatine, Swedish and Danish periods, or I may divide it by its chief battles, or by the alternations of Catholic and Protestant ascendancy, or in some other way. A class of boys I may divide into talented, mediocre and slow members, or into models and scapegraces, or into reliable and non-reliable students.

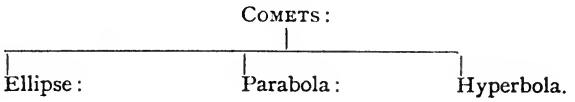
(3.) **The members or parts of the division,** to which apply nearly all the coming rules for division, may in their turn be divided ; and these subdivisions may likewise be regarded as wholes, and cut up into further divisions ; and so on through an interdependent series, by means of which we can see the whole in all its parts and in their mutual relations. Every subdivision is obviously subordinate to the division from which it is made, *e.g.*, wholes are divided into actual, potential and moral, while actual wholes are subdivided into physical, metaphysical and logical. Church history may be divided into periods of three hundred years, and each of these periods may be subdivided, and these subdivisions call for further division, and so on till our history is pretty fully mapped out.

XX. Rules for Division.

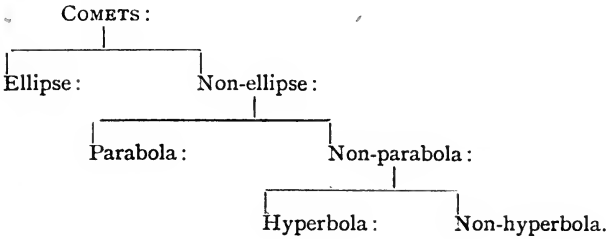
(1.) **The division must have a basis or founda-**

tion; for without it logical division would be impossible.

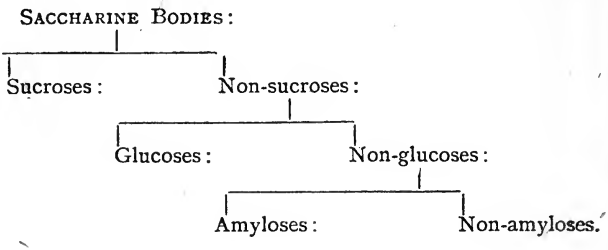
(2.) **It must be adequate and exclusive,** *i.e.*, it must contain every part of the whole, and only its parts. To secure this, the most logical way is to divide our whole or genus into two species only, one of which indicates a differentiating property, which the other denies, *e.g.*, if I classify comets according to their orbits:



It may be objected that it is not impossible for a comet to have, say, a circular orbit; but I can get out of every difficulty of this sort by stating my division thus:



It is evident that I have room here for every kind of orbit; and, if the next comet should happen to have a circular orbit, I can draw it or any other novel kind from my non-hyperbola. And, if I wish to make a perfectly good classification of saccharine bodies, I should state it thus:



But, if I divided all saccharines into sucroses, glucoses, amyloses, and glychol, my division would not be exclusive, for it contains something, viz., glychol, which is not a part of the whole, viz., saccharine. And, on the other hand, if I divided it into sucroses and glucoses only, my division would not be adequate, because it does not contain amyloses, which is a part of the whole.

(3.) **The parts of the division must be strictly co-ordinate:** hence no one of the parts can equal the whole, and no subdivision can stand in co-ordination with a primary division, or with any division higher or lower in the scale than itself, *e.g.*, suppose a school to be divided into six forms, and the first of those forms into two divisions, it would be logically inaccurate to speak of the division of the school as—first and second division, and second, third, and fourth form, for first form comprises first and second division, which are its subdivisions, and so are not co-ordinate with second, third, and fourth form. Similarly, to speak of Schiller's *Wilhelm Tell* as consisting of four Acts and the last three Scenes, or of Shakespeare's *Hamlet* as containing four Acts and two more Scenes, would be to give a faulty division, for in

each case the specified scenes constitute the fifth Act, which should be named in their stead.

(4.) **The parts of the division must mutually exclude each other,** *i.e.*, no one may be either partially or wholly contained in another. Thus, in the same division, I cannot divide Scotland into the Highlands and Lowlands *and* thirty-three counties, for the main division of Highlands and Lowlands includes the counties. Strictly speaking, this rule is not much more than an extension of the last. In some cases indeed, it is practically impossible not to violate it in the minor divisions of a classification; *e.g.*, in making a library catalogue, I may divide the books into those which treat of History, Biography, Science, Literature, Language, Geography, Art, Religious Questions, &c., &c.; but, however carefully I may make the classification, there will certainly be books in one class, which might equally well belong to another. Where shall I place a "Biographical History of Literature," for instance? It belongs alike to the History, Biography, and Literature divisions; and, if it should happen to be written in Russian or Chinese, why should it not rank under Language?

(5.) **The division must be regular or orderly.** This rule applies chiefly to subdivisions, which should be formed from the division next above them, so that there may be no break in the series of subdivided parts; *e.g.*, it would be incorrect to divide Logic into the matter of the act of the agent, and its form; for the primary division of agent, act, and end, which furnishes the whole, is ignored. In the same way, to divide the compounds of arsenic into

arsenic trioxide, arsenic peutoxide, arseniuretted hydrogen, arsenic disulphide, trisulphide, and pentasulphide, would be to leave out of count the previous division into oxides of arsenic, arsenic and hydrogen, arsenic and sulphur.

(6.) **Division should be short and simple**: hence it should be neither too comprehensive nor too detailed; otherwise, instead of furthering and elucidating a survey of the divisible whole, it will only render it laborious and puzzling. Labyrinthine subdivisions divert the mind from the main point, fix it upon minute details, and induce the very confusion they were intended to correct. Seneca says: "A thing divided to dust is as good as confused."

CHAPTER IX.

XXI. Argument. XXII. Demonstrative arguments. XXIII. Rules for demonstrative arguments.

XXI. Argument or Demonstration. After having defined the subject of our inquiry, and divided it into its component parts, the next step is to establish the truth of our assertion through the medium of principles or grounds. This is done by argument, or demonstration in the wide sense of the word, and its end is to verify objective truth, and make it certain to our minds. The value of an argument in establishing Truth and Certainty depends entirely upon its force and the degree of evidence it exhibits, which may be either convincing

in various degrees, or the reverse. From this point of view, all arguments fall into two great classes, viz. (1.) **Certain or Demonstrative,** in which the evidence is in itself convincing; and (2.) **Probable or Doubtful,** in which proofs are merely probabilities, and therefore are non-convincing. It is obvious that, of these two classes, only the first can be called demonstration in the strict sense of the word.

XXII. A Demonstrative Argument or **Demonstration** strictly so called, is the deduction of the truth of a proposition from another proposition already known and recognized as true; and this deduction is accomplished by means of the syllogism, with which we are already familiar. Going back upon our knowledge of it, we see then that the basis of all demonstration must be the axiom that "Truth contains nothing but the true." Consequently, whatever necessarily follows from a certain truth must certainly be true; if a truth could contain false consequences, it would *ipso facto* cease from being truth. Consequently again, because "Truth cannot oppose what is true," whatever either contradicts or is contrary to a certain truth, must certainly be false. Of two contradictories, we remember, one must necessarily be true and the other false; and, as two contraries cannot both be true at once, if one is true, the other must be false. To get a clear idea of Demonstration, we must distinguish at the outset between its Matter and its Form.

As the **Matter** of every argument, we have first of all something to be proved, and this is called the

thesis or **proposition,** which is specified as a **theorem** if it is of a theoretical nature, and as a **problem** if its character is practical. The main point at issue, defended or opposed by several theses, and usually stated in interrogative form, is known as the **Question,** and the elucidation of the main theses and their dependencies and sub-dependencies is called generically the development of the **State of the Question.** Then there is something by means of which the thesis is proved, and which is called the **principle** or **ground** of demonstration. It may be either **immediate,** *i.e.,* when its truth is at once evident to the mind without proof (*principium per se notum,* which when of a theoretical nature is called an axiom), or **mediate,** *i.e.,* when its truth has to be made evident by proof. In this case, the principle of demonstration consists of an agreement used as the *principium demonstrationis* in the agreement based upon it, and it should be either already itself proved, or at least provable. If not actually proved, it is really assumed, and as such is usually termed a postulate. Then we have the syllogism, by means of which the thesis is deduced from the principle of demonstration, and which, we know, may be either simple or compound, thus furnishing either a simple or many-linked argument.

In contradistinction to its threefold Matter, the **Form** of Demonstration, or that which makes it what it is, is the **necessary consequence** of the thesis from the principle of demonstration. Only where there is such a consequence can there be an argument, for on it rests the truth of the deduction.

Lastly, it must be noted that Demonstration is

essentially dependent upon the *principia per se nota*, without which argument would virtually be impossible. The reason is this. If every proposition taken for the ground of demonstration, required proof, we should go on seeking it for ever, and our argument would never come to an end, and consequently would cease to be an argument. We had a parallel case in treating of definition. Just as definition would be impossible unless it started from, or—as we regard it—led up to indefinable concepts, so would argument be impossible unless primarily based upon, or—from our point of view—leading back to indemonstrable propositions neither requiring nor admitting of proof. Such propositions are either indemonstrable truths of the reason, which form the limit of argument from above, and will be treated of later on, and indemonstrable facts of internal and external experience, which limit argument from below. What need is there to prove, or indeed *how* can I prove by argument that I am thinking what example will suit my present point, that I am writing at a wooden table, and hear the sound of merry boys' voices in the playground?

So much for Demonstration in general. Before examining its divisions, which might be the next step in our inquiry, we will look at the

XXIII. Rules of Demonstration, or the Demonstrative Argument, which relate (1.) to the **thesis**; (2.) to the **principle or ground of demonstration**; (3.) to the **syllogism**, as the instrument of argument, and are the following:

(1.) The rule for the **thesis** is that its sense should be so **clearly determined,** that nothing else

may be proved but what has to be proved. Hence, before beginning an argument, the state of the question should always be sufficiently explained and set out clearly. Especially is such explanation necessary when, without it, the thesis might have many meanings, or be otherwise obscure; and it stands to reason that the explanation should be adequate and most lucid.

(2.) The **principle of demonstration** should be

(a.) **true and certain,** for what is doubtful and uncertain cannot be a basis of proof. This rule applies chiefly to objective arguments, but it must not be violated in subjective arguments *ex concessis* (q.v.).

(b.) It must be **acknowledged as true and certain** before it can become the ground of the argument, or basis of proof.

(c.) It must be **better known than the thesis,** otherwise it cannot answer its end of proving or elucidating the thesis.

(d.) Finally, it must be **quite distinct from the thesis,** for it is the principle by which the thesis is made known. Hence it should not express the same thing, nor have the same nature as the thesis.

(3.) Lastly we come to the rules for the **syllogism** considered as part of the argument. First of all, there must be **no violation of the laws and rules for the syllogism** (q.v.); and, secondly, **all its parts must be in themselves true.** To put it shortly, the syllogism, or series of syllogisms, must, in their whole extension, be both formally and materially true. In this respect, therefore, all the rules for the formal and material truth of the syllogism

apply with equal force to the argument. In direct opposition to the three classes of rules for the argument, stand fallacies or sophisms.

CHAPTER X.

XXIV. Fallacies or Sophisms.

XXIV. Fallacies or Sophisms are errors or mistakes in reasoning that mislead or deceive, and may be defined, arguments which appear to be regular, but are not so really. Hence a sophism does not consist in a false opinion, but in the bad reasoning or faulty argument by which it is reached. Sophisms are treated of next after the rules for the argument, because—after seeing how we are to do the right—it is natural to look how we or our opponents may get wrong, and because all sophisms may be included in classes corresponding to the division of these rules, inasmuch as they violate the laws laid down for the accuracy either of (1.) the **syllogism,** (2.) the **thesis** or (3.) the **principle of demonstration.** Sometimes sophisms are divided into **logical or formal,** *i.e.*, reasoning wrongly from right premisses; and **material,** *i.e.*, reasoning rightly from false premisses. Though this division is not here adopted, the letter F will indicate formal, and the letter M material sophisms, as they occur in the classification chosen.

(1.) **Contrary to the rules of the syllogism** are the sophisms of,

(a.) Amphibology or Ambiguity—F.
(b.) Composition and Division—F.
(c.) Collective and Distributive meaning—F.
(d.) Passing from a "dictum secundum quid" to a "dictum simpliciter"—M.
(e.) Fallacia accidentis—M.
(f.) The false cause.—M.

(a.) **Amphibology** or **Ambiguity** is a fallacy occasioned by using a word of two or more meanings, sometimes in one, sometimes in another of these meanings during the course of the same argument. The way to unmask this, is to distinguish the meanings in the premisses: *e.g.*

No one smiles but man;
This meadow smiles;
Therefore this meadow is a man.

The fault really lies in putting more than three terms into the syllogism. In the major premiss of our example the middle term *smiles* is taken in its ordinary meaning, whereas in the minor term it is used analogically. Again, the agnostic uses a fallacy of ambiguity when he says; "that which becomes a cause has passsd beyond its former bounds," and uses this assertion to support the thesis that the Absolute and the Infinite cannot be the First Cause, in other words that, if there is a God, He cannot be the Creator, stated as a syllogism, it would stand thus:

A cause in becoming a cause passes outside its former bounds;
But in the Act of Creation God becomes a Cause;

Therefore in that Act He has passed outside His former limits.

But this is impossible; and hence God the Creator is an impossible being.

Now the word cause is here used ambiguously. In the major premiss it is applicable to created causes only; in the minor to the uncreated cause; so we must confront the false conclusion with an emphatic *distinguo*. And *distinguo* too we must say to the coachman, who having heard his master tell a friend that certain conveyances were under lock and key at his office, and that it had been horse-work to get them drawn up by a specified date, concluded that the lawyer had become somewhat disordered in his intellect if he could make such an assertion. "Conveyances" to the serving-man signified only the contents of the coach-house, and possibly "horse power" was identified in his mind with horses; certainly he did not know that the legal deed, by which property is conveyed from one person to another, is termed a conveyance.

(b.) **Composition and Division.** This fallacy consists in using words in a composite sense, which are only true in a divided sense, that is to say, to infer that two predicates cannot be affirmed of a subject successively because they cannot be affirmed of it simultaneously, *e.g.*,

It is impossible that one who is awake should sleep;

But "Brother Jonathan" is awake;

Therefore it is impossible that "Brother Jonathan" should sleep.

The opposite fallacy, that of Division, is to use

words in a divided sense, which are only true in a composite sense, *i.e.*, to conclude that because two or more predicates can be affirmed of a subject successively, they can, therefore, be affirmed of it synchronously, *e.g.*

It is possible for one who is sitting to walk;
But Hecuba is sitting;
Therefore she can walk while she is sitting.

The fault lies in inferring in the conclusion what is not in the premisses, in violation of the second rule of the syllogism. The way to unmask this fallacy is to test it by the rules of the conjunctive syllogism.

(c.) The fallacy of **Collective and Distributive** meaning consists in using a term in any argument first in a collective, and then in a distributive sense, or *vice-versâ;* thus giving four terms instead of three to the syllogism. As with the fallacies of ambiguity, we must distinguish the meanings in the premisses, *e.g.*,

The Apostles preached the Gospel to the whole world;
But James was an Apostle;
Therefore James preached the Gospel to the whole world.

Here "Apostle" is just used collectively and then distributively. It would be a similar fallacy to say that every soldier in the Greek army put one hundred thousand Persians to flight, because the Greek army (combined) did so;

(d.) The fallacy of **passing from a "dictum secundum quid" to a "dictum simpliciter;"** or *vice-versâ*. This is done when from a major premiss,

which is only true with certain limitations, or under given conditions, a conclusion is drawn without regard to such limitations or conditions; *e.g.*

What you have not lost you have;
But you have not lost £2,000;
Therefore you have £2,000.

Now, in this example, the assertion in the major is only true with the limitation, that you already possess what you have not lost; but the conclusion is drawn without reference to any such limitation. As an instance of the same case we may take:

At your Latin lesson to-day, you say what you studied yesterday;
But you studied decimal fractions yesterday;
Therefore you have decimal fractions at your Latin lesson to-day.

In the major, "the Latin you studied" is evidently implied, but no such circumstance is recognized in the conclusion. The reverse of this is, from a major premiss, which is only true when stated without limitation or condition, to draw a conclusion which could only be true if the major were limited or conditioned; *e.g.*

You will read to-day what I wrote yesterday;
But you will read the history of De Rancé to-day;
Therefore I wrote the history of De Rancé yesterday.

In both forms of this fallacy, the fault lies in inferring more in the conclusion than is contained in the premisses; and the error must be called from its lurking place by a prompt *distinguo*.

(e.) **Fallacia Accidentis.** This fallacy occurs

when, from the fact of individuals belonging to any species, it is inferred that they are necessarily endowed with some property or capability, which belongs to the species not essentially but only *per accidens;* or when, from seeing a thing, that is good in itself, frequently misused by many persons, we come to consider the thing itself evil, and so condemn the good with the bad; *e.g.* Among lawyers there are many pettifoggers; hence every lawyer is as such a pettifogger. Philosophers have already done much harm in the world by means of philosophy; therefore philosophy in general is calculated to cause harm. And Rousseau uses a *fallacia accidentis* when he says: "Science and literature have produced much evil; therefore they are evil." At the two poles of human society—saints and rapscallions—a frequent basis for practical argument is the proverb, "What man has done can be done by man"; but it is in point of fact merely an instance of the fallacy we are considering. A sickly inmate of St. Thomas's Hospital might conclude, for instance, that being a man he can, like the Stylites of old, live on the summit of a pillar, and proceed in consequence to rear for himself some such singular place of abode, say, in Regent Circus or St. James' Park. Would not the authorities civil and medical speedily furnish him with a certificate of lunacy? And some priggish ignoramus might contend that, men having written the *Summa Theologica*, the *Principia*, the *Grammar of Assent*, and *Metaphysics of the School*, all men can write books equally profound and closely reasoned, and therefore that such undertakings are within

the limit of his own capabilities, while in reality he perhaps represents the very apex of sciolism. Again, the socialist is only putting the same premiss into different words, when he urges that "What man has belongs to man," and therefore that the rights of property do not exist; that, if honour is paid to one, it is the right of all; that, if authority is vested in a few, it should be extended equally to all, which simply means that it must be reduced to *nihil*. Some of the Temperance Tracts published are filled with sophisms of this and the class that will next be considered. From seeing that the excessive use of alcohol is evil, many people conclude that alcohol itself is evil, which is a hardly more rational conclusion than it would be to assert that study *per se* is evil, and to be avoided, because excessive study has weakened some few intellects and impaired some constitutions. A very striking instance of the *fallacia accidentis* occurs in a book called *Natural Religion* by the author of *Ecce Homo*, who thus seeks to disprove the Personality of God: "Personality, as we know it, involves mortality. Deities are usually supposed immortal. Personality involves a body. The highest theologies have declared God to be incorporeal." Here we have muddled up the essence of personality with two accidents which happen to accompany it in man as he exists on earth. It would be about as reasonable for a Red Indian to say that, all personality, as I know it, implies a red skin; hence God must be red. From the examples given it will be readily seen that the fault lies in arguing from particular cases to a general one, when we have no right to attribute the

quality or property in question to the essence or specific nature of the individuals in question.

(f.) **The false cause, or non causa pro causa,** is a fallacy which consists in adducing a mere antecedent as though it were a cause, according to the old sophistical adage, *post hoc ergo propter hoc*, when there is no sort of *nexus* between them beyond that of temporal or some other sort of accidental sequence; *e.g.*, the fall of the Roman Empire followed the establishment and spread of Christianity; therefore the foundation and spread of Christianity was the cause of the fall of the Roman Empire. The appearance of a remarkable comet preceded the fall of Constantinople; therefore it caused the fall of the city. The prisoner at the bar passed through St. Pancras' Station half an hour before the dynamite explosion took place; therefore he left explosives in the Station. The fault in all these cases is easy to detect, and lies in nothing else but in basing the argument on the supposition that, if one thing follows another, the first must be the cause of the second, merely because it comes before it. Meteorologists tell us that people, who believe in the unvarying influence of the moon upon the weather, fall into this fallacy, when they attribute changes in the weather to the moon having entered upon a fresh phase; and that it is much the same thing to attribute exceptional cold to brilliant displays of the Aurora borealis.

(2.) Contrary to the rules of the **thesis** are the various sophisms classed under the

Ignoratio or **Mutatio elenchi,** (M.) when the question is evaded by tacitly ignoring or misrepresenting it. This is done by proving the wrong con-

clusion, that is to say, a proposition which—by more or less resembling the question—is likely to be mistaken for it. **Elenchus** is the name given by Aristotle to the contradictory of our opponent's statement, and this contradictory must be proved in order to refute him, successfully. The fault lies in violating the rules for proving the contradictory of propositions; and is distinguished as **Ignoratio** when committed unknowingly, and as **Mutatio elenchi** when committed designedly. The ways in which a question may be thus evaded are very various. Sometimes a meaning different from its real one is assigned to the thesis; and so a point is established quite different from the one which should have been proved; *e.g.*, suppose the thesis for proof to be, that man is free in so far as he is able to choose and decide in his actions; and instead of this it is proved that he is free in the sense of living under and being responsible to no law. And, if we argue that the Second Person of the Blessed Trinity, being God, must be eternal; yet, having been born in time, cannot be eternal; and therefore is eternal and not eternal; which is impossible; and hence, because He must be either the one or the other, He is either not eternal, and consequently not God; or he is eternal, and consequently not man; we are giving a false meaning to the thesis, which regards only the Nature of the Second Person of the Blessed Trinity while the conclusion not only refers to two but gets on the wrong track by assuming their union in one Person to be an impossibility.

Sometimes in refuting an opponent, something is proved which he did not deny, or something is

disproved which he did not assert; *e.g.*, when the Port Royal ladies were charged with Jansenism, they said they were not Jansenists but religious. This was clearly evading the question about as rationally as did the Irishman who, when charged with being drunk and disorderly on the evidence of five witnesses who had seen him so, proposed to call fifty witnesses who had not seen him. To prove what is not denied, and to disprove what is not asserted, are common practices in law courts, where they are often effectually used to produce a prejudice. A bank clerk, for instance, or a lawyer's cashier, pleads guilty to a charge of embezzlement; but urges in extenuation that he has been exposed to great temptation, misled by bad companions, and induced by the poverty or misery of his home to commit crime. In such a case, the counsel for the prosecution will, nine times out of ten, ignore the point in question, viz., whether the circumstances adduced extenuate the prisoner's guilt, and insist upon what is not denied, that he has actually committed the crime, and so must have been dishonest. Not many years ago, when two landlords went to law about the proprietorship of a small stream, which for some distance divided their respective estates, the counsel for the defence effectually created a prejudice and virtually determined the verdict by proving that in the title deeds of the defendant's estate there was mention both of the stream and of its name, while neither could be found in those of the plaintiff—a point which had never been asserted, and which—when the case was taken to a higher court—proved quite beside the question.

Sometimes again, this fallacy takes the form of proving too much or too little,—which is, in point of fact, to misrepresent the question. In proving too much, people draw from an argument not merely the conclusion which formed its thesis, nor further conclusions legitimately drawn from it, but other consequences which are false and often absurd; this, for instance, is what the materialists do with their assertion that the brain is the thinking principle within us, when they say: thought is dependent upon the brain; hence the brain itself is that within us which thinks. Now this is clearly to prove too much; for it would follow that in every case in which one efficient cause was dependent for its action on another efficient cause, the principle of this action would be the cause on which the immediate efficient cause of the action was dependent: this illustration shows the force of the saying: he who proves too much, proves nothing. Too little is proved when part of the thesis is suppressed; and though the conclusion may be true of that portion which has been made the matter of argument, it cannot be true of the thesis as a whole, and so cannot be brought forward at its conclusion; *e.g.*, if anyone, in proving free will, made use of an argument from which could be inferred only part of that freedom, it might be quite true with reference to that part, but it would be valueless as a proof of the whole of the thesis. So again, if I had to prove that a class of ten boys had passed their examination, and I only proved that some two or three had done so, I should be proving too little, and evading part of the question, and, if I had to prove to an

anxious parent that his boy had been eminently successful, and I wandered away into proofs of the eminent success of every boy in the College, I should on the contrary, be proving too much, to say nothing of making myself a very decided bore.

A further way of evading the question, and proving the wrong conclusion is, in weighing alternatives, to keep out of sight those that we have some interested motive in ignoring, and to rest our argument on those that coincide with our views. Suppose, for instance, a young fellow wants to go to sea, and asks his father whether or not such a course would be advisable for him. We will suppose the father to be a confirmed landsman, intolerant of salt water and her Majesty's navy in general, and of her Majesty's midshipmen in particular. In ninety-nine cases out of a hundred, such a man would bring forward a whole litany of objections against his son's wish, and think that the force of the objections should prove that he ought to abandon it. Here we have nothing but an *Ignoratio Elenchi;* for the point proved is, merely that there are weighty objections against the plan; while the point that ought to have been proved is, whether there are more weighty objections against its adoption than against its rejection, or *vice-versâ*, *i.e.*, whether the arguments in its favour outweigh those adduced against it. Similarly, people of every shade and degree of prejudice, are apt to keep out of sight, or at any rate to under-estimate every alternative which clashes with one of their foregone conclusions. A report is set in circulation to the discredit of Tostig Harold; it reaches the ear of John Thomas who,

for some reason, has power to investigate it; John Thomas has a settled aversion to Tostig Harold, and is not in the habit of giving him credit for good intentions; but, in the present case, he professes strict impartiality, and "talks big," as our American cousins say, about daily balancing *pros* and *cons*. Is it likely that his prejudice and aversion will keep out of the scale? Not a bit of it. Just as the land-loving, sea-hating father is trapped into a fallacy, so, if we may believe the evidence of everyday facts, does the strictly impartial John Thomas evade the question by ignoring the *pros* for Tostig Harold, and establishing a wrong conclusion supported on the *cons plus* aversion and prejudice. Such, unfortunately for the interests of truth, is the method of procedure adopted by a certain class of writers who, while professing to be above prejudice, are so far its victims that they give to facts the colour of their prepossessions, and only take cognizance of such arguments as lie along the narrow vista they see before them.

(b.) This appears to be the right place to point out the mistake—which hardly seems to be recognized by logicians as a fallacy—of supposing that the failure of an argument proves the opposite conclusion. Logically it cannot do so; for, as we saw in treating of propositions, though the falseness of one contrary may be inferred from the truth of the other, yet from the falseness of one the truth of the other may not always be inferred, because sometimes both contraries may be false. Practically, however, the failure of an argument may tend to, and indirectly strengthen the proof of the opposite

conclusion. In a court of justice, for instance, when the case for the defence breaks down, it cannot be inferred that the case for the plaintiff will necessarily be established, though this often takes place in fact.

(3.) Contrary to the **principle** or **ground of the argument,** are the fallacies of:

(a.) Begging the question . . M.
(b.) The vicious circle . . . M.
(c.) False generalization . . M.

(a.) **Petitio principii,** or **begging the question,** consists in taking for the ground of the argument, and so assuming as true, what requires to be proved. This may occur in different ways, though some logicians limit the extent of the *petitio principii* to its most usual form, which is to say the same thing twice over in different words, and then make one statement the proof of the other. Thus the thesis is made to do duty for the ground of the argument, and the former is proved by means of itself, *e.g.*, if I say that the soul is immortal because it lives for ever, or because it never dies, I am making a true statement twice over, but I am not proving the immortality of the soul. If I try to prove that the earth moves round the sun, and argue that because the sun is at rest (as regards the earth), the earth moves round the sun, I am begging the question: for, in saying that the earth moves round the sun, I imply that (with regard to the earth) the sun is at rest, and hence I take for the ground of my argument something contained in the thesis. Molière gives us a capital instance of this form of the fallacy in the physician Ignarelle, who tells the father of a

dumb girl that her infirmity is easy to explain, "she has lost the power of speech." "Yes, yes," presses the father, "but the cause, if you please, why she has lost the power of speech." "All our best authors will tell you," readily retorts Ignarelle, "that it is the impeding the action of the tongue." Again, why can I see through glass? Because it is transparent. Why can I break glass? Because it is brittle. Why cannot Ernest see? Because he is blind:—are all cases in which I beg the question, and prove nothing, because my proofs are no proofs whatever, since the thesis is repeated in different words.

Another way of begging the question is to use a word signifying disapproval, *e.g.*, unfair; and then say because some act or other was unfair, it should not have been done. For instance, James got his marks unfairly; no one should get marks unfairly; therefore James should not have got his marks. The argument looks quite right; but it should first of all have been proved that the marks were got unfairly in the accepted use of the term; instead of which this is taken for granted. Personal or corporate infallibility, too, is taken for granted in arguments based on such phrases as, "I have never heard of such a thing," "*we* have never taught that," "it is not according to *my* ideas," "it does not please *my* eye." Some examples: When Buckingham, urging that the young Duke of York ought not to have the right of sanctuary at Westminster, argues

> Oft have I heard of sanctuary men,
> But sanctuary children ne'er till now,

he is basing his argument on the suppressed premiss,

"whatever I have never heard of cannot possibly be right"—an assumption which any man living has a right to call in question. And, when old world teachers demur to accept the results of modern investigation and discovery, on the mere plea that "we have never taught that," the ground of their argument is the lucid if not luminous statement, "whatever we have never taught cannot possibly be right"—a very patent absurdity. "Is this book suited for young people?" "Certainly not; it is not according to my ideas." "A proof *that*, which requires to be proved," any sensible man would mentally ejaculate. A group of young people are "doing the critical" in the National Gallery; they stop before a picture. "Something wrong in that drapery," remarks one. "Quite sure of it," puts in another, "it does not please my eye." "Humph," thinks a more logical passer-by, "what displeases that young person's eye cannot possibly be right. Surely this basis of argument calls for proof." Many of these examples might be adduced equally well as instances of the fallacy *non causa pro causa;* but this fact does not make them severally any the less a *petitio principii*, for in each the ground of the argument is a gratuitous assumption demanding proof. The same may be said of the widely accredited piece of fallacious reasoning, that "as the non-existence of space cannot by any mental effort be *imagined*, therefore the non-existence of space is absolutely *inconceivable*." Without striking into deeper strata than we are examining in these simple Logic lessons, we shall, if we examine this specious argument carefully, find a place for it in several classes

of fallacies. Confining our attention, however, to its basis or ground, we see that it rests on the suppressed premiss that, *what we cannot imagine we cannot conceive*, a statement in which there is a palpable error of confusion, material imagination being confused with immaterial thought, and practically identified with it. Until they are proved to be identical, I accept no conclusion based on their identification.

(b.) The **vicious circle.** This fallacy consists in proving one thing by means of another, and that other by the first of the two things thus presumably proved, *i.e.*, the thesis by the ground of demonstration, and this last by the thesis. For instance, to prove the existence of God from the existence of the world, and then to prove the existence of the world from the existence of God, would be to argue in a circle. The longer the chain of reasoning in which this is done, the more likely is the fallacy to escape detection. To take other examples: if I try to prove a boy's diligence during Term by his success at the examination, and then prove his success under examination fire by his diligence during Term, I am very palpably arguing in a circle. Under a cloud of words to conceal the device, this was the method of reasoning used not long ago about a controverted will, which was declared genuine because it bore the signatures of witnesses and testator, while the genuineness of their signatures was next deduced from the genuineness of the will itself. These two instances will serve to show, however, that the fallacy in question takes place when we are arguing with one person, or rather with one partisan or

opponent (these may sometimes be a collective body); for it is obvious that, in arguing separately with many persons, it is quite legitimate to make the thesis of our argument with one, the ground of our argument with another, for then the two arguments are quite distinct; *e.g.*, it may be allowed that a boy has been diligent during Term, but denied that his examination was a success; while someone else may consider his examination brilliant, but call in question the Term's diligence. Now, if I have reason to believe that he was both diligent and successful, there can be no possible objection to my naming his diligence as a proof of his success to one person, and his success as a proof of his diligence to somebody else; and no one can charge me with arguing in a circle. And a man believing in the genuineness of the controverted will, was quite justified in bringing forward the signatures as a proof of its genuineness to one party, and to another its intrinsic genuineness as a proof of the genuineness of the signatures. If a negress, recently freed from slavery, came to me believing neither in freedom nor in responsibility; and if, in the attempt to rectify her ideas, I proved responsibility from freedom, and then proved freedom from responsibility, I should certainly be arguing in a circle, and possibly leave her ideas as much confused as would be my own reasoning powers. We will suppose that the good woman's husband comes in search of her. To meet the requirements of our example, he must be my next disciple. I find he has a very decided belief in freedom, but is innocent of any faith in responsibility; so I indoctrinate him on the matter, basing

my argument on freedom. Before the week is ended, I go into the hospital and find there a poor Indian woman converted to Calvinism some years ago. That there is such a thing as freedom, she will not admit; but her sense of responsibility is helping to kill her. If, for her comfort, I sit down by her side, and bit by bit prove freedom to her very simply, basing my argument on responsibility, no one will dream of saying that I am arguing in a circle, because, only a few days before, I had made freedom the basis of my argument for responsibility with the negro.

In purely objective scientific arguments, however, we must always suppose that we are arguing only with one person, and so must never under any circumstances make use of an argument of which we have the conclusion in one of the premisses, *i.e.*, argue in a circle.

(c.) **False generalization,** or **invalid induction** consists in making the ground of the argument a proposition which seems to be universal, but is not so really, and then arguing from the simulated universal to particulars. Instance the celebrated sophism: Epaminondas said, All Cretans are liars; but Epaminondas was himself a Cretan; hence he lied; hence the Cretans are not liars; but Epaminondas was a Cretan; hence he did not lie; hence the Cretans are liars; and so on *in infinitum*.

Under the head of false generalization fall naturally all violations of the rules for the validity of induction, which we shall speak of just now, even though they may not be directly contrary to the rules for the ground of demonstration, and though

they may also belong at the same time to some other class of fallacies than that of invalid induction. Thus we sometimes argue that what is true of many things considered universally, is also true of something which does not come under the rule; in other words, we give to a mere moral universality the scope of an absolute universality; *e.g.*, we know that the French as a nation hate the Germans; but we have no right to infer that all the French in London hate all the Germans in London, or that all the French boys in a cosmopolitan college hate all the German boys. In the same way, because Presbyterians as a body exclude enjoyment from their Sunday programme, we cannot infer that this will necessarily be the case in every Presbyterian family. In these instances the fault lies in extending the generalization too far.

Sometimes also, we argue that what is true only of some things in a class, is true also of all things in that class as such. This we have already considered as the *fallacia accidentis*, in which we err by arguing from a particular case to a general rule, as did a maiden lady of an uncertain age, who, on hearing of the dynamite attempt upon the Tower and Houses of Parliament, declared that public buildings *en masse* had been proved dangerous, and therefore she would never again enter one, "no, not even a church."

Again, we sometimes argue from a particular case to another particular case, which has only an apparent and not any real connection with the first. This is sometimes called the fallacy of *a non tali pro tali*, and is only a kind of fallacy of false analogy (q.v.); *e.g.*, it would be simply absurd to argue that,

because I may kill a man in self-defence, I am at liberty to kill Carey for abandoning the Prince Imperial in danger, for there is no parallel whatever between the two cases. And for the same reason, when Gordon was holding Khartoum, I had no ground for concluding that, because the French had the worst of it at Sedan and Metz, General Gordon would have the worst of it at Khartoum; though this need not have prevented me from thinking upon quite other grounds that his chances of success were never higher than a minimum. Sophisms, which under one aspect may be classed as fallacies of ambiguity, may from another point of view have a still better claim to be regarded as instances of the form of false generalization with which we are at present engaged. In proof of this, some of the examples given of the fallacy of ambiguity may be re-examined. Passing to a fresh one, we find a little fellow innocently juggling with the word *light*, and reasoning from special cases to other special cases, between which there is not the connection assigned as the ground of the argument. He may say, for instance, "Fire and gas and lamps are light, and they do burn my fingers; how the little boys and girls in the transformation scene of the pantomime must be burning; how the big light moon would burn my finger, if I could put it in."

In concluding this outline of the sophisms, it may hardly be necessary to note that, when we have detected one flaw in a specious piece of reasoning, it does not follow that we have discovered all its weak places; for, as has been shown, a single false argument may contain more than one fallacy,

and a single fallacy may belong at once to more than one class: hence the saying "a fallacy is a nest of fallacies"; and hence too the parts of the division of fallacies cannot mutually exclude each other.

CHAPTER XI.

XXV. Kinds of demonstrative arguments.

XXV. Kinds of Demonstration or Demonstrative Arguments.

According to the point of view from which they are regarded, Demonstrative Arguments may be:

(1.) a priori, or a posteriori;
(2.) direct, or indirect;
(3.) objective, or subjective;
(4.) progressive, or regressive;
(5.) main, or subordinate;
(6.) deductive, or inductive.

(1.) A priori or a posteriori.

(a.) An **a priori** argument is one in which the proposition, that is the ground of demonstration, is also either the objective reason, or the cause of the thing we are proving: hence, in an argument *a priori*, we reason either from the reason to the result, or from the cause to its effects, or from the essence of a thing to its properties; *e.g.*, we can prove responsibility from free-will, which is its reason, inasmuch as responsibility results from free-will; we can prove the existence of the natural order of the world from the infinite goodness and wisdom

of God, as effect from cause; and we can prove the immortality of the soul from its spirituality, thus deducing a property from the essence.

(b.) An **a posteriori** argument is one in which the ground of demonstration is the objective result or effect of the thing proved: hence we argue from the result to the reason, or from the effect to its cause, or from the properties of an object to its nature; *e.g.*, we argue *a posteriori* when we prove free-will from responsibility, because we argue from the result to its reason; in proving the existence of an all-wise and beneficent Creator from the existence of the natural order in the world around us, we argue from the effect to its cause; and, in proving the spirituality of the soul from its power of thought, we reason from a property to the essence.

Thus, in demonstrating anything *a priori*, we proceed from what is prior to what is posterior in the order of *things*, quite independently of our knowledge; while in demonstration *a posteriori*, on the contrary, we begin with the matter of our previous knowledge, *i.e.*, with what is posterior in the order of *things*, and lead back to what is prior. Mathematical proofs, for instance, are of the *a priori* kind; whereas the conclusions of experimental science are gained *a posteriori*. Why the latter method should be queen-regnant in the domain of historical criticism, and why the *a priori* argument nevertheless holds a corrective office there, we cannot learn better than from the great Belgian Bollandist, Father de Smedt, S.J.[1]

[1] *Principes de la Critique Historique*, chaps. ii. and xvii.; and *Introductio Generalis ad Historiam Ecclesiasticam critice tractandam*, tract. i.

(2.) **Direct or Indirect.**

(a.) **Direct** arguments are those in which the truth of a thesis is proved in such a way as to show that the thesis is already granted implicitly, or rather potentially, in granting the ground of the argument, and so must be true in consequence of that ground being true. Hence, the middle term of the syllogism must be some *undisputed* truth, which either agrees or disagrees with the extremes of the proposition; *e.g.*, if in proving the incorruptibility of the human soul, I take for the ground of proof the proposition, "the soul thinks," and from thought deduce the immateriality of the soul, from this its simplicity, from its simplicity its indissolubility, and therefrom its incorruptibility, my argument would be a direct one. And so too is the following: Immutable Being is eternal; God is immutable Being; therefore God is eternal.

(b.) **Indirect** arguments are those in which the truth of a thesis is proved by demonstrating the falseness of its contradictory. To demonstrate the falseness of this contradictory, we should show the false or absurd consequences that inevitably result from it; and from these consequences deduce the falseness of the source from which they flow, according to the axiom: What is false results only from what is false. Under this aspect, that is to say, inasmuch as the contradictory of the thesis is carried on to its false and absurd consequences, the indirect argument is called an **argumentum vel reductio ad absurdum**; *e.g.*, if I were to say, in proving man's free-will: If man were not free, he would not be responsible, for he would be incapable

of responsibility; if incapable of responsibility, he would be incapable of merit, of sin, of reward, and of punishment; but all this we know to be false and absurd; hence man cannot be not free, *i.e.*, he must be free,—my argument would be obviously a *reductio ad absurdum*. Again, in proving the moon to be an opaque body, we argue indirectly when we say, we know that the moon's interposition between the sun and the earth occasions an eclipse of the sun; but, if the moon were a transparent body, her interposition would not obscure the sun's light; hence she cannot be transparent; hence she must be opaque. The indirect mode of argument is often used in mathematical demonstration, *e.g.*, one line is proved to be equal to another, by proving that it cannot be greater, and that it cannot be less; it must be either greater, or less, or equal; so, when we have shown that it is neither greater nor less, we have indirectly proved that it must be equal.

Thus, we see that a direct, or—to give it its technical names—an apodeictic or ostensive argument, goes straight from the ground of demonstration to the thesis; while an indirect or apagogic argument, on the contrary, goes in what may be called a roundabout way, by first of all proving from the ground of demonstration the falseness of the contradictory of the thesis, and not till then proving the truth of the thesis. The scientific value of the direct argument is clearly greater than that of the indirect, because the direct shows how and in what degree the thesis must necessarily be true, and indirect arguments do not do this. Their force, however, is in no way less than that of the more satis-

factory and scientific direct arguments; and their use is a necessity when, from the nature of the case, apodictic demonstration is impossible. To demonstrate directly the falseness of perfect scepticism, for instance, is an impossibility, because there is no foundation for an argument, that is not pre-occupied by doubt. Under its interdict lie the infallibility of the reasoning faculty and of the understanding, as well as the formal laws of thought. But we can expose its intrinsic absurdity thus: either the sceptic doubts the truth of his scepticism, or he does not. If he does doubt, the categorical enunciation of his doubt is absurd. If he does not doubt, he gives the lie to his own system, seeing that there is something about which he does not doubt, viz., his philosophy of doubt.

(3.) **Objective or Subjective.**

(a.) An **objective** argument (**argumentum ad veritatem**) proceeds from a general principle of demonstration, and therefrom proves the thesis, without taking into account our partisan or opponent's frame of mind, or the manner of regarding the matter, which he has made his point of view.

(b.) A **subjective** argument (**argumentum ad hominem**), on the contrary, is one in which we place ourselves at the point of view occupied by the person for or against whom we are arguing, and argue from some principle which he recognizes or accepts as true, that is from his "professed principles." This may be done in two ways, viz., either by putting ourselves on a level with the persons with whom we are arguing, and proving our thesis from such principles as we know they cannot fail

to understand; or by arguing *ex concessis*, that is by taking as a principle of demonstration something already granted or conceded as true by our adversary, and from it either proving to him the truth of a proposition, or disproving his false thesis. In this last case the argument is called Retorsion; we had an example of it in showing how a dilemma can be turned against ourselves.

Objective arguments are sometimes called **absolute,** because the general principles from which they proceed are certain, and should be universally admitted: while subjective arguments are called **relative,** because their principles, if not universally admitted, must at least be held to be true by those with whom we argue, whether these principles be in themselves true or not. In seeking truth for its own sake, and hence in purely scientific matters, we must obviously make use of objective or absolute arguments; but, in demonstrating or pressing a point home to individuals, and perhaps still more to masses of men, it is equally clear that a subjective or relative argument will serve our purpose better; and it is perhaps so true of nothing as of these two classes of arguments, that "what is best in itself is not always the most expedient." As instances of each kind, we may contrast a judge's "summing up" of a trial with the speeches made by parliamentary candidates when canvassing for votes before an election. The judge's summary of evidence is an evident case of an argument *ad veritatem*, and so, according to *Blackstone*, should be the preceding speeches made by the counsel for plaintiff and defendant respectively.

This accounts for the value attached to "precedent" in legal decisions, which have to do with an objective standard of right and wrong explained and elucidated, though not primarily determined by "law," and so which are not swayed by subjective or personal arguments. The speech of a parliamentary candidate, on the other hand, must be very largely an *argumentum ad hominem*, if it is to attain its end, and help the speaker to a seat at Westminster. In insisting upon a point, it might be in itself the best, but it might be far from the most expedient to argue from a general fact or principle as such, for probably half his hearers would be unable to follow him; but, if the same point were put before them as the outcome of their professed principles, or as being necessary to the consistency of their avowed line of conduct, the candidate's chance of success would be far greater, in so far as it depended upon argument, which—as a matter of fact—is by no means the largest factor in working the sum of popular votes. Some of the best examples of an *argumentum ad hominem* may be found in St. Paul's Epistles, *e.g.*, to those who admitted Christ's teaching, but denied that we shall rise again from the dead, he says that, if it is true that we shall not rise again, Christ did not rise again; if He did not rise again, His preaching is vain; and if his preaching is vain, our faith also is vain; but it is admitted that He rose again, that His preaching is not vain, and that our faith is not vain: hence, *ex concessis*, it must be admitted that we shall rise again from the dead. The familiar story of the young rhetorician

and his master well exemplifies the *argumentum ad hominem* in the form of retorsion. An old sophist undertook to instruct a young rhetorician in pleading, on the understanding that he should be paid when his pupil gained his first cause. The master sued for the reward, whereupon the scholar sought to evade the claim by a dilemma. "If I gain my cause, I shall withhold your pay, because the award of the judge will be against you; if I lose it, I may withhold it, because I shall not yet have gained a cause." Whereupon the master retorted: "If you gain your cause, you must pay me, because you are to pay me when you gain a cause; if you lose it, you must pay me, because the judge will award it."

(4.) **Progressive or Regressive.**

(a.) **Progressive** arguments or, as they are sometimes called, **synthetic,** are those in which we start from the ultimate principle or ground of demonstration, and from it descend through a series of syllogisms to the thesis, *e.g.*, I meet with a man who, from professing general "know-nothingness," has come to question the very palpable evidence of sense that he is a *substance,* yet, with strange inconsistency, concedes, the substantiality of living beings in general and as such. Quite enough that for my purpose:

Living being is substance;
But an animal is a living being;
Therefore an animal is a substance.
But man is an animal;
Therefore man is a substance.
But you, Malcolm Mactab, are a man;

Therefore you, Malcom Mactab, are a substance.

(b.) In **Regressive,** or **Analytic** arguments, we go through the precisely reverse process, *i.e.*, we prove the thesis by the principle of demonstration from which it immediately proceeds; then prove this by the one next above it; and so on through the series till we reach the ultimate principle or ground of demonstration; *e.g.*, Malcolm Mactab's nephew, Duncan Dewdrop, shares his uncle's difficulty about self-substantiality, but concedes only that he was Duncan Dewdrop yesterday, is Duncan Dewdrop to-day, and was Duncan Dewdrop grinding at Latin gerunds ten years ago. Yet Duncan Dewdrop, you *are* a substance, because

Duncan Dewdrop is a man;

But man is an animal;

Therefore Duncan Dewdrop is an animal.

But an animal is a living being;

Therefore Duncan Dewdrop is a living being;

But living being is substance;

Therefore Duncan Dewdrop is substance. Other examples of this way of arguing have already been given in treating of the polysyllogism (q.v.).

(5.) **Main or subordinate.**

(a.) A **main** argument is that one which has the greatest force with reference to the thesis, inasmuch as it really proves it; *e.g.*, a notorious burglar charged with breaking into a house at Hammersmith, is discharged without much examination mainly because he can prove an *alibi*, and show that, at the time of the robbery, he was actually finishing a term of imprisonment at Cardiff.

(b.) **Subordinate** arguments are such as serve, by

their connection with the main argument, to elucidate the thesis still further by showing its truth when regarded from other points of view. Of themselves they would not be sufficient to establish its truth in the given case; but in dependence on the main argument they are most useful in making this truth clear when regarded in various aspects. Examples of subordinate arguments will often be found among the proofs for the **necessity** of anything, *e.g.*, of law, of which the need becomes more and more apparent according to the number of aspects under which it is regarded.

(6.) **Deductive or Inductive.** Before distinguishing the kinds of demonstration known as Deduction and Induction, it may be well to make the preliminary observation that the popular meaning of these two words in English seems to be an exceedingly vague one, which, like all other vague meanings, is apt to be misleading. All reasoning of the kind we have been considering, is marked off in an indefinite sort of way as deductive or syllogistic, because we deduce or lead down the truth from premisses to a conclusion; while induction is held to be the process of collecting and investigating facts, forming hypotheses, and then deducing inferences from the hypotheses, to which the facts when ascertained have given birth. On the face of it there are at least two big blunders to start with in any such explanation as this. In the first place, the definition of formal logic must have made it clear that, as far as induction is taken to mean a process of inquiry, it is altogether outside the province of formal logic, the office of

which is, not to *get* premisses, but to see if any, and what conclusions can be drawn from them when got, no matter how. In the second place, when we deduce inferences from the hypotheses which are the result of our fact-gathering, what are we doing but going through a process of deductive reasoning capable, like every other such process, of being thrown into syllogistic form? Hence, the rules for Division, which we have already studied, will tell us that, in the popular acceptation of the terms, Induction includes Deduction, and so that the distinction must be inadequate, and consequently that the Division is faulty. How Induction—as a process of reasoning—is reducible to the syllogistic form, and is in fact nothing else but a syllogism, we shall see just now. So far it is clear that, though Deduction and Induction have each a distinct meaning of their own, it is not that which passes current in ordinary parlance. Equally untenable too is the view which identifies Deduction with Demonstration, and considers Induction as an essentially distinct form of reasoning, having nothing whatever in common with Demonstration. So far is it from being essentially distinct from Demonstration, that it is nothing whatever but one of its many forms, standing to it in the relation of species to genus; for the simple reason that, as Demonstration or Demonstrative arguments are, in contradistinction to probable arguments, those in which the thesis is *shown* to be certain, or is "proved to demonstration," and as this is likewise done by Inductive reasoning, Induction must be comprised among

the various kinds of Demonstration. Hence too, Deduction cannot be identified with Demonstration, or it could not be contrasted with Induction which is a form of Demonstration; for it would be a very incorrect division indeed—in fact no division at all—that would seek to contrast a whole with one of its parts. Supposing, for instance, we tried to divide fan-tail into fan-tail and fan; or lion into lion and mane; or "honourable stops," as a writer in *Merry England* has called them, into stops and colons.

(a.) In its wide meaning **Deduction** may be taken as identical with every argument *a priori* (q.v.); but strictly speaking, as the correlative of Induction, it is a particular form of the *a priori* argument, one in which we draw out a particular from a general truth, on the assumption that what is true of the whole must be true of each part. Its most general formula is that, **what is or is not predicated of the universal, is or is not predicated of the particular.** Thus we reason deductively from the genus to the species, and from the species to the individual, *e.g.*

Every animal has five senses;
But the horse is an animal;
Hence the horse has five senses.
Every horse is a quadruped;
But Bucephalus was a horse;
Therefore Bucephalus was a quadruped.

In these two examples the *a priori* element in deduction is readily discernible; for the horse has five senses *because* it is an animal; and, if Bucephalus had not been a quadruped, he would not have been a horse.

(b.) **Induction**, in its wide meaning, is a simple

synonym for every argument *a posteriori;* but, taken in its exact signification, it is that form of the *a posteriori* argument, in which we reason from the parts to the whole, or from the particular to the general or universal, *i.e.*, from individuals to the species, or from like facts or phenomena to a general law, according to the formula that, **what is or is not predicated of every particular, is or is not predicated of the universal.** Herein the *a posteriori* element at once reveals itself; for, when we argue from the particular to the general, we have *eo ipso* an argument from result to reason, or from effect to cause, seeing that particulars stand to the universal, under which they are comprehended, in the relation of result to reason, or of effect to cause. For instance, when we find that all birds we know of have warm red blood, and infer that warm red blood is an essential property of all birds, we argue from result to reason; and when, from seeing that bodies are always expanded by heat, we conclude that the expansion of bodies by heat is a universal physical law, we argue from the effect to its cause. In both our examples, we have gone through the process of inferring that a proposition is true universally from finding it to be true in a number of particular instances; but in neither case is our conclusion based on an enumeration of *all* the particular instances that might be adduced. Hence our induction is an incomplete one. Indeed there are very few cases in which induction can be complete, *i.e.*, in which all the individuals comprised in a species, or all the cases in which the effects of some particular law of nature are observable, can be enumerated. Besides

being practically impossible, such an enumeration would be simply useless, for then we should be arguing not from the particular to the general, but from all individuals to all individuals again, from the known to the known, not from the known to the unknown; *e.g.*, we should be wasting words to no purpose if, to someone who knew that the family of Sennacherib Scatterbrain consisted of three sons, we said—Peter, James and John Scatterbrain are all in London; therefore all the sons of Sennacherib are in London. So it comes to this, that our enumeration, though not exhaustive, must be sufficiently full to warrant our drawing the conclusion that, what is true of the individuals or of the particular cases, is true also of the species or of the general law; and to do this rightly we must act upon the axioms that form the very basis of Induction, viz., that **like principles have like results,**—and **like (physical) causes like effects.** Only by proceeding from these principles can we form a true inductive argument. The reason is a simple one. When, from observing that a certain property belongs to all the individuals of a species, that fall within the limits of our personal experience, we conclude that the property in question is to be found in all other individuals of the species, we do so because we attribute the property to the specific nature of the individuals, as to its principle, on the ground that the same specific nature as the principle of these properties and qualities, must be accompanied by them as its results. Similarly, in leading back from effect to cause, and arguing from the constant uniform recurrence of certain phenomena

observed by us, that in all other cases unknown to us they actually exist, we attribute the phenomena to the specific nature of their common cause, on the ground that like physical causes, in so far as their action is unimpeded, must always produce like effects. No explanation is needed to show that the two principles we have been considering are first principles; hence they must be both universal and necessary, and moreover be in themselves sure and certain. From this therefore we **conclude:**

(*α*) that the truths or conclusions arrived at by means of Induction are universal and necessary, because they result from the application of general and necessary principles to what is particular and contingent; for instance, our two examples about the warm red blood of birds, and the expansion of bodies by heat, are undoubtedly universal and necessary, *i.e.*, there is no exception to the rule, and every individual case proves its necessity.

(*β.*) Yet, in the case of a general law of nature, the universality and necessity ascertained by means of Induction only are conditional; for it may happen that the action of some other law of nature may under certain circumstances interrupt the action of an otherwise uniform law, or that this last may be sometimes suspended by the interposition of God's power; *e.g.*, it may be that, under some exceptional circumstances, heat will not expand a body in consequence of the counter-action of some other physical law. And, although it is quite true that the law we have gained from induction—"every body which is specifically heavier than water sinks in water"—is in itself both necessary and universal; yet, by the

miraculous intervention of God's power, there have been exceptions to this law, as, *e.g.*, when our Lord Himself and some of His saints during the last eighteen centuries walked upon the waters.

(γ.) Lastly, an Inductive argument, being grounded on principles that are sure and certain, is in itself, or essentially, a perfect demonstrative argument. Where there is question of a universal law of nature, the conclusion gained by induction from the given principle is only hypothetically certain; but under the specified conditions it is certain, and remains so as long as these conditions last; and this is quite enough. No one can reasonably doubt, for instance, that heat expands bodies, and that bodies specifically heavier than water sink in water, unless the action of some other law, or the direct interference of Divine Power cancels the conditions on which the uniformity of such laws depends.

To make our inductions valid, however, we must observe the following **rules**:

(α.) In reasoning from the individuals to the species, it is not sufficient to argue from a few instances; we must extend our inquiry so far at least as to make it embrace really representative members; otherwise we shall not have a sufficient basis for our argument.

(β.) Then we must be careful not to mistake merely accidental qualities for those that are essential, and so fall into a *fallacia accidentis*, which has been already explained.

(γ.) In reasoning from phenomena to a general law, our observation of the phenomena should be as wide as possible, and be followed by repeated and

various experiments. Observation and experiment are not in themselves Induction any more than they are Logic; but they are the necessary means by which certain premisses may be obtained for inductive reasoning.

(δ.) It is further necessary to ascertain whether the phenomena observed are uniform and unvarying effects of the action of the physical cause assigned to them. If exceptions to the rule occur, an inquirer should then get to know whether they are to be explained by other causes, and whether these causes modify or even nullify the law he is seeking to deduce from the phenomena. Exceptions, for which an obvious explanation can be given, do not weaken an inductive argument; but, when there is no satisfactory way of accounting for them, they of course render valueless the premisses against which they militate, and which consequently cannot form a certain basis from which a universal law may be inferred. Hence Logic forbids our using them in any argument that we put forward as demonstrative.

Now, if Logic has a right to do this, it is again evident that Induction must fall under its laws; and, if it falls under the laws of Logic, **Induction** must either implicitly or explicitly be **in logical form**; and the form of Logic we have shown to be the syllogism; hence Induction must itself be a syllogism either openly or in disguise.

(*a.*) To take, first of all, an example of perfect or complete induction. If I say: Mercury, Venus, the Earth, Mars, &c. (naming all the planets) receive light from the sun; therefore all planets receive light from the sun,—I am plainly enough using the

REESE LIBRARY OF THE UNIVERSITY OF CALIFORNIA

incomplete syllogism called an euthymeme, in which one premiss is suppressed, though understood; so that my argument can be thrown into regular syllogistic form thus:

Mercury, Venus, the Earth, &c. (naming the rest) receive light from the sun;

But all planets are Mercury, Venus, &c. (naming the rest);

Therefore all planets receive light from the sun.

This is a very good instance for illustrating the uselessness of complete induction; for, if I say that each planet individually gets light from the sun, I am only saying the same thing in different words when I state in the conclusion that all planets do so.

(β.) In Incomplete Induction, too, we are really reasoning from a suppressed premiss, viz., either from the proposition, that because certain quality is found in all the observed individuals of a species, it belongs to the species as such, *i.e.*, to the specific nature of the individuals; or from the kindred proposition, that because a certain phenomenon is always seen to result from the action of some physical cause, it must have its origin in the specific nature of that cause. What right we have to make use of these premisses, we shall see by recalling the explanation of the application to induction of the principles on which it rests; and that explanation will show us further that an induction is essentially dependent upon a middle term, and that, although we speak of reasoning from particulars to the universal, we are in point of fact reasoning from what is universal in those particulars back to its

reason or cause, as the case may be. Thus our argument, that because all the birds we know of have warm red blood, warm red blood is an essential property of all birds, implies the first of the proposed propositions as one of its premisses, implies consequently a middle term, implies moreover an argument from what is universal in the instances adduced to the reason from which it results, *e.g.:*

Because the quality of having warm red blood belongs to all known birds, it must be part of their specific nature;

But unknown birds have the same specific nature as known birds;

Therefore (according to the axiom, like reasons have like results), the quality of having warm red blood must belong to the unknown as well as to the known birds, *i.e.*, be a universal and essential property of the species.

Against the validity of incomplete Induction as a form of syllogising, it may be urged that it violates one of the most important rules to be observed in reasoning, viz., that the conclusion should not have greater extension than the premisses, *i.e.*, contain anything that is not in them. Now the species has greater extension than the individuals from which the specific quality is inferred, or—to speak more accurately—the specific quality considered either actually or potentially *per se* has greater extension than the instances of it known even to the widest experience; and the whole has greater extension than its parts; and the cause, as container, has greater extension than its effects, which are to it as things contained. How is the difficulty to be met?

Some logicians thought to manage it by adding to their enumeration, "and so of the rest," or "and so of every other," *e.g.*, This body is heavy; so is that one; and so is every other body; But this, and that, and every other body are all bodies; therefore all bodies are heavy. At best such a method is very unsatisfactory; for it strives to make the induction complete by means of a mere assumption, and then makes the conclusion nothing but an amended repetition of a very clumsy first premiss. But, if we choose one of the two propositions proposed at p. 131, to do duty for our missing premiss, we shall have in that premiss either the specific nature of the individuals, or the specific nature of the cause which produces certain effects, according to the requirements of our argument; and so shall not lay ourselves open to the objection that our conclusion has greater extension than our premisses. So much for the form of Induction, to which the definition of the syllogism[1] will be found to apply as strictly as to Deduction.

A word remains to be said of the **value and scope of Induction.**

Its scientific value is nothing less than enormous; for by it we come to know the essential characteristics of the species or classes to which observation extends; and by it, and by it alone, inasmuch as we arrive at the knowledge of universal laws by the conclusions drawn from the uniform recurrence of phenomena, can we discover the laws of physical nature. In the first case, it is one means of gaining correct ideas and giving correct definitions; in the

[1] See p. 32.

second case, it is the only means and the necessary means of establishing and pursuing and perfecting natural science. Witness the history—if we may so term it—of the discovery, the testing, and ultimate verification of the law of gravity.

The reasoning we are all of us, more or less unconsciously, going through during the day is, for the most part, nothing but induction and analogy and hypothesis, resulting from observation. A child reasons inductively when, from seeing snowdrops in many gardens every January since his powers of observation began to develope, he argues that it is a property of all snowdrops to flower early in the year. But statements which are the outcome of merely enumerative induction are usually temporary and liable to correction, for the obvious reason that they do not—according to the laws of valid induction—lead back to the cause or principle *viâ* the specific nature of the individuals enumerated. Hence, in our every-day reasoning, the proportion of the *bonâ fide* inductive element is small compared to that of hypothesis and analogy.

That Induction cannot be used to demonstrate matters of faith, we shall see later on; but it was yet to be noted here that it can have no application whatever to facts of the moral order, because any unvarying uniformity in such acts is impossible, for the reason that they are dependent not on a necessary, but on free rational causes; hence a universal law cannot be inferred from them. From any uniformity that is observable in facts of the moral order, we can only conclude—at the very most—that under certain circumstances or con-

ditions, people will usually act in one way, and not in any other. But from this we cannot further conclude with any kind of certainty, that some particular person will, under precisely these circumstances or conditions, act in the one way which we know to be usual; still less have we any right to conclude that he ought to do so.

Having now got some notion of the Demonstrative Argument, we must next take a little look at the Probable Argument, *i.e.*, an argument of which we prove the conclusion by some probable medium; for we often find that an argument adduced in support of a thesis has not the force of certainty but only of probability.

CHAPTER XII.

XXVI. Probable arguments.

XXVI. Probable Arguments are of three kinds, viz., of

(1) Analogy;
(2) Congruity;
(3) Hypothesis.

(1.) **Analogy.** In reasoning by analogy, we conclude that two or more objects, which either resemble or are unlike each other in several or many qualities, will probably resemble each other or else be unlike in some other qualities; and, applying this to causes, we infer that because two or more causes have many qualities in common, they will likewise have effects in common; and conversely that, if their

qualities as causes are unlike, they will also differ in their effects. When, for instance, we conclude from the flattening of the earth at the poles, that our globe must originally have been a soft mass, we are reasoning analogically, because our argument is based on the analogy between our earth and any ball revolving on its own axis; the likeness between the two consisting in globular form and revolution round axis. Now, as such a ball revolving round its axis is not flattened at its poles unless it be soft, we infer that the earth must have been originally soft, for otherwise it would not be flattened at the poles. This example can be put into an experiment of twisting a ball of soft clay or dough rapidly round a cane, and then doing the same with a ball of worsted, or the hardest ball through which we can force the cane. Again, we are using an argument by analogy when we infer the attraction exercised by the sun upon the planets, from the influence of the earth upon the moon, or from the attraction exercised by the earth upon all bodies that come within its influence.

All such arguments are based on the axioms: "Similars agree with similars; dissimilars with dissimilars;" and, "Similar causes produce similar effects; dissimilar causes, dissimilar effects." Yet these axioms are not of universal application, nor are they verified in every case; hence they cannot form the basis of perfectly demonstrative arguments, but only of such as make the thesis for proof more or less probable. The greater, however, the similarity between the things compared, the higher is the degree of probability established, so that now

and then conclusions resting on analogy may even appear to amount to certainty. But as, generally speaking, this kind of argument produces nothing beyond probability, there is always something uncertain and unsatisfactory in endeavouring to establish a thesis solely by means of analogy. At least, in such a case, no sort of unconditional certainty can be claimed for the conclusion, though—as a matter of fact—this is too often done. To strengthen, or rather to tell out and give circumstantial cogency to a demonstrative argument, analogy may be very useful; but, in a general way, it has itself but little force; and is more effectually used to silence objections than to prove or discover truth. In the use of analogy, care must first of all be taken to ascertain that the similarity or dissimilarity between the things compared or contrasted, is a real, and not merely an apparent one; and during the argument the analogy must not be extended further than the actual relation between the things warrants.

Argument by analogy may be threefold, viz.:

(a.) **A pari,** when the relation between the things is one of simple similarity; *e.g.*, Fortitude is commendable; therefore, *a pari*, is temperance commendable. When the sun shines brightest, sensible vision is not the most distinct; therefore, *a pari*, in the sunshine of prosperity our intellectual vision is not the most piercing. And the parent used an argument *a pari* when, in consoling his children for their disappointment on hearing that it was impossible for the robins to have given a leafy covering to the *Children in the wood*, he told them that, as

somebody[1] describes himself, when he was a child fallen asleep in a desert wood, covered with leaves by the wood-pigeons that took pity on him, so might the dead brother and sister have been cared for by the pitying robins. And, as Cassandra in the streets of Troy was obliged to prophesy, although she knew no one would believe her, so *a pari* are preachers or writers sometimes obliged to address auditors or readers who, they know, will neither heed them nor believe.

(b.) **A fortiori,** when there is not merely similarity between the things compared, but when the points of similarity belong in a much higher degree to the thing we are arguing about than to that or those with which it is in analogy; *e.g.*, arguing from the greater to the less—an angel cannot create anything; therefore *a fortiori* man cannot do so: and, from the less to the greater—detraction is evil; therefore, *a fortiori*, calumny is evil. When, in his *Analogy of Religion*, chapter 5, Bishop Butler compares analogically the present life, as forming the proper preparation for another, to childhood as a preparation for manhood, he naturally draws out his argument *a fortiori*. Of the same nature was the argument suggested by the poet Coleridge in showing his weed-covered garden to Thelwall. It was the opinion of the latter that it would not be right to bias the mind of a child by instilling into it opinions before it should have arrived at an age to judge for itself. "I showed him my garden," said Coleridge, "and told him it was my botanical garden." "How so," he replied, "it is covered with weeds." "Oh!"

[1] Horace, *Od.* iii. 4.

rejoined the poet, "that is only because it has not yet come to its age of discretion and choice. The weeds, you see, have taken the liberty to grow, and I thought it unfair in me to prejudice the soil towards roses and strawberries."

(c.) **E contrario,** when the analogy is that of contrast or opposition; *e.g.*, virtue is praiseworthy; therefore, *e contrario,* vice is blameworthy. Energy of will is the life of the intellect; wherever it is, there is action and animation; therefore, *e contrario,* where it is not, all is listlessness, dulness, and desolation. Innocence gives ease and freedom to the mind; therefore, *e contrario,* guilt disquiets and fetters it. Generous appreciation of merit brightens the reputation upon which it breathes; jealous depreciation, *e contrario,* blasts and withers it.

(2.) **Congruity.** An argument from congruity is one which brings out with greater clearness the truth of a proposition (already proved in some other way), by showing how it agrees with or is *congruous* to other truths of which we have certain knowledge. This kind of argument cannot, under any circumstances, be used to prove the truth of a thesis in the first instance. It takes that for granted, for its office is only to show the consonance or harmony of the proposition with other truths, and thereby to bring *its* truth into bolder relief, and so make it clearer to the eye of reason. Hence, being insufficient to prove to demonstration a truth not yet established, arguments from congruity have *per se* only the value of probable arguments. Such, for instance, are all the arguments made use of to make the mysteries of Christianity acceptable

to reason, for they do not make the truth of the mystery certain to us to begin with. That has been done by Faith. They are only used to make the truth clearer to our minds. For the most part such arguments fall into some one of the classes of arguments from analogy.

(3.) **Hypothesis.** By hypothesis we understand some proposition, which we have gained neither from induction nor deduction, but have merely assumed, in order to explain by it certain phenomena, because we think they can be rightly deduced from it; or, more shortly, it is something not proved but assumed for the purpose of argument. But, because the basis of such an argument is merely conjectural, it has received the name of hypothesis, which is the Greek word for supposition.

Hence, it is evident that no hypothesis has any scientific value until it has been shown how and why the phenomena in question may be accounted for by it. But even then the hypothesis is only more or less probable; for it may happen that the same phenomena may be equally well accounted for by some counter hypothesis. When there are thus two hypotheses, one seemingly as good as the other, it is necessary to test them by some facts or things which will agree with one and not with the other, and thus increase the probabilities in favour of one of the two hypotheses. Such facts or things are called crucial instances, and the experiment in which they are thus applied is termed an *experimentum crucis*. Hence, to make any hypothesis certain, we must seek to place it on a further basis

of purely scientific principles. When its adequacy has been inductively tested by such principles, and it is found to offer the only satisfactory explanation of the phenomena, to the exclusion of every other hypothesis, we may come to regard it as certain, or as a law of nature. Such, for instance, are Newton's Law of Gravity, and the Copernican hypothesis of the movement of the earth round the sun. In the same category scientists would probably place the undulatory theory of light, the luminous ether which is the medium of its transmission, and the vibratory theory of sound, which were in the first instance brilliant conjectures, and have passed into the range of scientific facts only because they explain what, on any other hypothesis, known to us, is inexplicable. Their certainty, therefore, is at best only a sort of provisional certainty. The word *theory*, which has several various meanings, is in science applied to a well verified, though not necessarily perfectly verified hypothesis.

If any hypothesis is to be held sufficient for the basis of an argument, it should fulfil the following conditions:

(*α.*) it must not be intrinsically absurd or contradictory;

(*β.*) it must not be in contradiction with the established truths of experience, faith, or science;

(*γ.*) it must not seek to obviate the difficulties to which it gives rise, by means of fresh hypotheses;

(*δ.*) it must explain *all*, not merely *some* of the phenomena in question;

(*ε.*) lastly, it should only be adopted and applied,

when the cause or reason of the phenomena in question has not yet been, or perhaps cannot ever be ascertained by any scientific method.

CHAPTER XIII.

XXVII. Scientific knowledge. XXVIII. Object of scientific knowledge. XXIX. End of scientific knowledge.

XXVII. Science or Knowledge, or more exactly, **Scientific Knowledge,** "the result or outcome of demonstration," as it is called by St. Thomas[1] may be regarded either **subjectively** or **objectively.** In the first of these two aspects, *i.e.*, **subjectively,** it may mean either the cognitions we receive by means of the light of reason, and so be placed in contradistinction to the teachings of experience and faith; or it may signify only our cognition of the truth of a proposition by means of *mediate* reasoning; and, as the mediate light of reason depends on demonstration, knowledge is in this sense defined to be, "the certain cognition of an object, which is acquired by means of demonstration," Then—to quote St. Thomas again—as "Demonstration, which gives us knowledge of a thing, proceeds from its causes."[2] Scientific Knowledge must be closely defined as "a certain and evident cognition of the **causes** of the things known." These causes are of four kinds: (1.)

[1] In lib. i. *Poster.* lect. viii.
[2] Lib. i. *Sent.* dist. xlv. q. 1, a. 3. ad. 5.

efficient, *i.e.*, that which by its action produces the thing. (The word *action* specifies the efficient cause, and marks it off from all other causes); (2.) **material**, *i.e.*, that element in the thing, which is in itself undetermined, viz., matter, but is capable of being determined by another, *i.e.*, by the (3.) **formal** cause or form, which is that which determines matter, and so makes it what it is; (4.) **final**, *i.e.*, that which is aimed at by the efficient cause,—in other words, the end of an action. Thus, a sculptor is the efficient cause of a statue by his action in making it; the stone or marble he works upon, is the matter or material cause of the statue; the shape he gives to it, is its form or formal cause, and is that which *makes* a statue what it is; the end or motive he or his employer has in view, is the final cause of the statue. Viewed without reference to the statue, the stone or marble is, of course, a substance made up of matter and form; the components being the matter; their union or combination, the form; the physical action, which produced that union, the efficient cause, but a secondary efficient cause dependent on and acting directly by the power of God—the first and highest of all efficient causes. There is a great deal to be learned about causes; but this brief indication of their nature will perhaps suffice to make clearer the definition of Scientific Knowledge in its subjective aspect.

Objectively considered, Scientific Knowledge means the collection of ordered truths within a given sphere acquired by demonstration, and *so* known and ordered according to their causes and laws. When we know some few isolated facts or

phenomena in their causes, we may, of course, be said to have a scientific knowledge of them as units; but this does not form Scientific Knowledge as a whole. That can only be attained by placing such known units in their right relations to each other, and so forming them into a united order, developed from and dependent upon some central point of union. This must necessarily be the first principle of a science; and the order dependent upon it, is called a system. Hence Science, or Scientific Knowledge as such, is essentially system, and consequently its essential form must be systematic; for, where there is no system, there can be no science or Scientific Knowledge. Now we can understand why it is called the result of method; for, in forming a system, the first thing to be done is to define the whole and its parts; the next is to make a right division; the next after that is to prove or establish the parts or separate truths, and either to lead them up to, or else deduce them from their first principle.

To sum up: Science or Scientific Knowledge is considered subjectively when regarded as an accidental quality inhering in the person possessing it; objectively, when it represents the objects of such cognition. Hence, as St. Thomas says, "there are three, and three only requisites for science; viz., the active faculty of the thinker by which he judges of things, the thing thought and the union of the two,"[3] *i.e.*, A subjective intellect, an objective fact or truth, and the representation of that truth in the intellect.

The truth or accuracy of a scientific system

3 *De Verit.* q. 11. a. 1, b. 3,

depends naturally on a number of **conditions or rules,** of which the following are the chief:

(a.) First and most important of all, the first principle, on which the whole system depends, must be true, and true as the first principle of the science built up thereon; otherwise the whole system will be wrong, Hegel's first principle, for instance, *i.e*, that thought and being are identical in idea, makes his whole system false.

(b.) We must start from the right point, and use the right method. This we should not do, if, in philosophy for instance, we began from the point—which in fact is an utterly pointless one—of universal doubt; and if we applied deduction and *a priori* arguments to natural science. Thus we should make both the whole as such and all its parts utterly wrong.

(c.) The laws and rules of Definition, Division, and Demonstration or Argument, must not be violated either with regard to the whole or its parts; or else there will be plenty of flaws in the system.

(d.) Every part of the system must be kept in its natural place, *i.e.*, in that by means of which it is in its right relation to the other parts. This is of the very essence of division; and consequent upon it is the caution to avoid digressions. What confusion we should introduce into Logic, for instance, if in treating it synthetically, we studied all about the syllogism before we had learned anything about propositions. And if, in speaking of nominal definitions, we had digressed into a treatise on derivation, how completely out of proportion would that part of the

text-book have been with the other parts, and so with the whole.

(e.) Every part of the system must be set forth with the proofs corresponding to and necessary for it; and nothing needing proof must be admitted there without proof. To this rule, however, every *lemma* is an exception. A lemma is something borrowed from another science, and assumed to be true on its authority. Though, as we use it, it may need proof, we are not obliged to give it; for we have a right to suppose that it has been verified in the science to which it belongs.

(f.) Consequences, which follow immediately from the ascertained chief principles of a system, may be immediately added to them as corollaries, in order to bind together things that are closely interconnected. Corollaries are evident, or at all events practically evident consequences, in which the deduction is so apparent that proof of them is considered unnecessary.

Having seen the conditions upon which the truth of a system depends, we shall be prepared to look at two other things regarding Science or Scientific Knowledge; viz., its Object, and its End.

XXVIII. Object of Science or Scientific Knowledge. Every Science has its determined object, *i.e.*, that about which it treats; and this object may be either **material or formal.** The **Material Object** indicates the matter of the Science considered generically; the **Formal Object** is that particular part or aspect of the Material Object, which the Science professedly contemplates, and which forms its adequate and distinctive "subject-

matter." Hence, it may happen that several Sciences have the same Material Object; yet, as they all regard it under a different aspect, or are specifically given to distinct parts of it, their respective Formal Objects are quite distinct. Thus *man* is the material object of medicine, anatomy, ethics, physiology, etc.; but *man* as a free moral being, tending by his free-will to his constituted end, is the formal object only of ethics.

From this it will be seen that the material object of a Science designates its class; while the formal object specifies the Science, and so differentiates it from all other members of its class. Furthermore, the object—and usually the material object—indicates the degree of superiority or inferiority of a science in the catalogue of the sciences, *i.e.*, their **sub,** or **super-ordination** with respect to one another. Thus experimental are subordinate to mental sciences; and of two experimental sciences that one ranks higher whose object approaches more nearly to the suprasensible, *e.g.*, language as the immediate expression of thought is higher than physical science; while among mental sciences the speculative rank higher than the purely formal, *e.g.*, Philosophy is superordinate to mathematics; and at the summit of Philosophy, and so of all sciences, stands the science of Metaphysics, because it has to do with those things which are most of all others intelligible, *i.e.*, being and those things which follow from being, whence its name of Metaphysics, *i.e.*, beyond physics; the first causes of things, whence it is called First Philosophy; God and the intelligences, whence it is termed the

Divine Science. (See the *Proœmium* to St. Thomas' Commentary on Aristotle's Series of Treatises on Metaphysics). In Metaphysics then we find the watch-tower to which Bacon refers, when he tells us that, if we would grasp and understand any particular science, we should not "stand on a level with it, but climb up, as it were, into the watch-tower of some other science," and thus place ourselves in a position to take in all its parts.[4]

In speaking thus of the subordination of the sciences, and claiming the presidency for Metaphysics, it must be understood that we have only in view the sciences acquired by processes of reason. Dogmatic Theology, which is in its very nature paramount, belongs to an altogether different order; and, though it cannot run counter to science, has an object, a basis, and a source altogether different from those of science.

Quite distinct from the Subordination of the Sciences, which implies no interconnection whatever, is the **Subalternation** of Sciences, which consists in the fundamental dependence of some sciences on, and hence of their inferiority to others. This takes place when a science, having no axiomatic or self-evident truths for its first principles, borrows principles from some higher science, called the subalternant or governing science in reference to the inferior of subalternate. They are taken for granted by the lower, because they are scientifically proved by the higher science. Thus perspective and music borrow their first principles from the higher science of mathematics. Where such dependence exists,

4 *De. Aug. Scient.*, Works, vol. i. p. 460, ed. 1857.

the material object of both sciences is the same; but in the inferior science a certain difference is added, which suffices to constitute a specially distinct formal object; *e.g.*, *number* forms part of the formal object of mathematics, *sounded number* is the formal object of music. In like manner, the *line* enters into the formal object of mathematics; the *visual line* is the formal object of perspective.

XXIX. End of Knowledge, or Science. Primarily, the end of science can be nothing else but the attainment of Truth, and this should always be its first and highest aim. It is sometimes called the **theoretic,** in contradistinction to the secondary end, which is distinguished as **practical,** and consists in the endeavour to further the interests either eternal or temporal of mankind,—an endeavour which cannot be realized by science except through the realization of its primary end, *i.e.*, the attainment of Truth. Equally true is this of what, consonantly, to the distinction between the subjective and objective aspects of Scientific Knowledge, may be called its **subjective** end, which has been apophthegmatically expressed in the saying that "Philosophical, or Scientific Knowledge is its own end," a proposition developed in Cardinal Newman's sixth discourse on the Nature and Scope of University Education. The reason has its foundation in our very nature; and, according to Aristotle, is threefold. First, because everything naturally desires its own perfection; and hence the intellect being *in potentia* with regard to knowledge, and being only brought into act by its means, naturally deserves it. Secondly, because everything has a natural inclination towards

its proper operation; and hence, as the operation proper to the intellect is to understand and reason, man is naturally drawn to understand, and consequently to know. Thirdly, because everything seeks to be united with its principle; and man is not united to the principles of human intelligence save by means of intellect. Hence it is not vain to seek science for its own sake apart from utility, for a natural desire cannot be in vain; and its realization satisfies an actual need of our nature. We all remember the line: "*Felix* qui potuit rerum cognoscere *causas*." Here we have subjective scientific knowledge and its subjective end; while both the one and the other connote *that*, without which they would at once cease to be, viz., Truth and Certainty; and so we come at last to the **End of the Act of the Agent**, or **Material Logic**.

C.

THE END OF THE ACT OF THE AGENT,

OR

MATERIAL LOGIC.

CHAPTER I.

I. Material truth of thought. II. Relations of the mind to Truth, viz., Ignorance, Doubt, Opinion, Certainty. III. Kinds of Certainty.

In tracing the plan of this little work, we saw that the end of the act of the agent in logic consists in the **attainment of truth and certainty**; and so, in treating of that end, we have to consider:

I. What the material truth of thought is, and what error is.

II. The fourfold relation in which our minds may stand in regard to Truth, viz., Ignorance, Doubt, Opinion, and Certainty.

III. The Kinds of Certainty.

IV. The Sources of Knowledge, as means of attaining Truth, and as motives of Certainty.

V. The Criterion of Truth and Principle of Certainty.

VI. The Laws or Rules on which depends the Material Truth of thought.

I. Material Truth of Thought. As distinguished from the Formal Truth of Thought, which consists in the conformity of the thought with the formal laws of thought, and so is sometimes called "Logical Truth," Material Truth is defined, "the **conformity** of the mind with the object," or, to

put it more closely, the conformity of the judgment formed by the intellect with the object of such judgment, *i.e.*, a correspondence between the representative thought and the represented object. Hence its name of **Conceptual Truth** in contradistinction to purely Logical Truth; while both are essentially Subjective Truth, *i.e.*, Truth existing in the mind of the thinker. It is obvious that Conceptual or Material Truth does not require an exhaustive representation of the object of Thought, and certainly does not suppose any full knowledge of, or absolute resemblance to it. This would be utterly impossible to such limited cognitions as ours must be in this life. All that is needed is, that what we know of the object should actually correspond to it; just as a photograph corresponds to the person it represents, though it does not show the whole of the person, nor is there any absolute resemblance between the glass or paper bearing the portrait, and the flesh and blood of the person.

Material Error, as opposed to Material Truth, consists therefore in a want of correspondence between the object as it really exists and as the mind conceives it to exist, *i.e.*, between the judgment of the intellect upon the object and the object itself; hence in a **difformity** between the thought and its object; but not in the incompleteness of the thought.

From this it will be evident that Material Truth belongs primarily to the judgment pronounced by the mind in joining together ideas, not in the inadequate representation of the object

in the first instance; for until some sort of judgment has been formed, the thought cannot yet be said to be either conformable to the external object, or wanting in such conformity. And it is the same with error, which resides in the judgment, and not in simple apprehension. The reason is this. Material or Conceptual Truth consists, as we have seen, in a conformity—hence an equation—between the intellect and its object. But conformity is not identity, because an equality of *distinct* things; hence there must be a difference between the representing thought and the represented object. In simple apprehension there is no such distinction discoverable, for the concept is merely an intellectual transcript of the original; hence there is identity between the representation and the represented. Not so in judgment or statement, which, as judgment, has no counterpart in the thing represented, in which there is no separation, while in a judgment there is the separation into subject and predicate, and there is also the copulative verb *to be*, which is altogether excluded from the object represented. Hence a conformity or equation is possible, because there is a distinction. This explains too why error is called "Assent to a false proposition," or "Dissent from a true one;" assent and dissent essentially implying a judgment of the mind.

As conceptual Truth resides primarily in the judgments of the intellect, as the judgments of the intellect are of many kinds, and, being acts, are differentiated by their object, it follows

that there are many classes of conceptual truths. Chief among them are the following:

(1.) **Truths supra-rational and rational.** Rational truths are such as we come to know either immediately or mediately by means of reason, and in the latter case are able to prove by argument. Supra-rational truths, on the contrary, are such as we could never know either immediately or mediately by the light of reason, nor prove to demonstration by its principles when we have obtained the knowledge of them by means of Revelation. Who can know from reason, or give demonstrative proof, for instance, that God while one in essence is three in Person? But it is an immediate truth of reason that a thing cannot be and not be in the same relation; and the rational truth that God exists admits of strict syllogistic proof. We may here draw attention to the distinction between judgments that are **according to reason** and those that are **contrary to reason.** Of these the first-named are in accordance with rational principles and truths, while the second are in direct contradiction to them; *e.g.*, a circle is identical with a triangle; a part is larger than its whole. Now what is contrary to reason can never be true. Supra-rational truths, consequently, must be according to reason. They are so either negatively or positively; negatively when it can be demonstratively proved that they are not in contradiction with rational principles and truths; positively when, by arguments from congruity, they can be shown to be in actual harmony with rational truths.

(2.) **Truths necessary and contingent.** Neces-

sary truths are propositions whose contradictory cannot possibly be true. They are absolutely necessary when this contradictory can be true under no condition whatever; *e.g.*, there is no effect without a cause; they are hypothetically necessary when the truth of the contradictory is impossible only under certain conditions, *e.g.*, man cannot live without air, because God has made it a condition of his physical life. Contingent truths, on the other hand, are propositions whose contradictory, considered simply in itself, might be true; *e.g.*, the world exists, because the world, as contingent, might at any moment cease to exist.

(3.) Truths a priori and a posteriori. Propositions of which we have only to know and compare the component terms, in order to recognize their truth, are called *a priori* truths, *e.g.*, the whole is greater than one of its parts. Such truths are as such always universal and necessary. Propositions for which we require some further reason than this comparison of terms, in order to recognize their truth, are called *a posteriori* truths, *e.g.*, heat extends bodies. These truths may be universal and necessary; but they are not always so; *e.g.*, this blotting-paper is pink, is both singular and contingent; and the universal proposition, Heat extends bodies, is only hypothetically necessary.

(4.) Truths analytic and synthetic. In an analytic truth the predicate attributed to the subject is virtually contained in the concept of the subject, *e.g.*, a circle is round: in a synthetic truth the predicate lies beyond the concept of the subject, and hence the reason why the predicate

is attributed to it cannot be sought for in the subject itself, *e.g.*, the earth moves round the sun.

(5.) Truths ideal and experimental. In the former the matter of the truth is suprasensible, *e.g.*, God is eternal Wisdom; in the latter it is gained by means of immediate experience, *e.g.*, boys are noisy, some old people are fidgetty.

(6.) Truths mathematical, physical, and metaphysical. Mathematical, *i.e.*, a proposition relating to a mathematical quantity or power, *e.g.*, twice three are six; physical, *i.e.*, a proposition expressing some physical law, *e.g.*, a body at rest remains at rest until set in motion; metaphysical, *i.e.*, a proposition referring to the ultimate reasons or first causes of being, *e.g.*, the human soul is a spiritual being.

7. Truths moral and religious. The matter of a moral truth relates to the moral order; the matter of a religious truth relates to the religious order; *e.g.*, we must be just to all men, is a moral truth; we must honour God, is a religious truth.

(8.) Truths theoretical and practical. Theoretic truths refer to being as such, *e.g.*, every effect has a cause; practical truths relate to action, *e.g.*, charity to others is a virtue to be cultivated.

These various classes of truths form the principal matter of our cognitions; and from them we pass on by a natural transition, to consider the

II. Attitudes of the mind with respect to Truth. The relation in which our minds stand with regard to Truth is a fourfold one, viz.:

(1.) Ignorance;

(2.) Doubt;

(3.) Opinion;
(4.) Certainty.

(1.) Ignorance, or complete absence of any knowledge of a truth, is clearly enough not a positive, but a merely negative relation of the mind towards truth; or, more exactly, no relation whatever, but the absence of such relation. It is universal until the faculties of cognition in man become active; and after that it is in every mind partial, for it is impossible to know all truths, and we must necessarily be in ignorance of those of which we know nothing.

(2.) **Doubt** is either objective or subjective; **objective** when it is in the proposition, *i.e.*, when a proposition is based on grounds which do not exclude the possibility of its contradictory, and so which prevent the proposition itself from being received as a demonstrated truth. **Subjective,** or mental doubt, is the state our minds are in when we cannot choose between two contradictory propositions, because *to us* the reasons adduced for neither of them exclude the possibility of their contradictory; hence it is called, a state of mind in which we suspend assent for fear of falling into error. "This takes place," says St. Thomas, "either because the mind sees no reason for assenting to either contradictory; or because the reasons for assenting to both appear to be of equal weight." [1] In the first case the doubt is **negative;** in the second, it is **positive.** To both applies St. Bonaventure's description of doubt, viz., "the indifference of the judgment to two contradictories, so that it chooses

[1] *De. Ver.* q. xvi.

neither in preference to the other."[2] The terms **reasonable** and **unreasonable** doubt speak for themselves.

(3.) **Opinion,** like doubt, can be considered either objectively or subjectively. Taken **objectively,** an opinion is some proposition, for the truth of which there are sufficiently weighty grounds to induce an upright sensible man to accept it as true, though all possibility of the truth of its contradictory is not excluded. **Subjectively** considered, opinion is the state of mind we are in with regard to such a proposition. We hold it to be true, because we think the reasons which go to prove its truth are sufficient to do so; but we are not quite free from the fear that its contradictory may turn out to be true. Whence such a mental state may be called—an assent of the intellect to one of two contradictories, yet with the fear that the one not assented to may be true; or, as St. Thomas puts it[3] "that state in which the mind adheres to one side of the question, yet with fear of the opposite." It adheres to one side, either because it sees the reasons for that side only, or because—seeing the reasons for both sides—it holds that they are more cogent for one than for the other. Yet it fears the opposite, because the reasons, in both cases, are not such as to produce steady unqualified assent to the proposition. Examples of this are constantly met with in persons whose struggles with their opinions keep them out of the Church long after they have felt the insecurity of their position as heretics or non-believers. Their

[2] In lib. iii. *Sent.* dist. xvi.

[3] 2a. 2æ, q. ii, a. i, c.

belief in their own system has come to be a mere opinion joined to a very real fear that what is attracting both heart and intellect to the Church may be true. And then, when they reach the stage preceding the conviction which in most cases of conversion goes before and prepares the way for the gift of Faith, the position of their opinion is sometimes reversed. They think they see sufficient reason for joining the Church, but fear that what they are leaving may after all prove to be true. That there should be many degrees of probability in opinions, is of course natural and necessary; and it is only rational to accept a more probable opinion on any matter in preference to one less probable. Objectively, the degree of probability attaching to an opinion, depends upon the force of its sustaining reasons *per se;* subjectively, it depends upon the mind's apprehension and acceptance of those reasons; hence our expressions, that opinion *commends itself to me* as highly probable, I have *strong reasons* for holding this opinion, etc.

(4.) Lastly, we come to **Certainty,** which is **objective** as a quality of propositions, and subjective as a state of the human mind. A proposition is objectively certain when the reasons adduced for its truth exclude the possibility of its contradictory. Hence objective certainty must be synonymous with Truth, or rather what is *per se* certain must be true. **Subjective** certainty or certitude (which is the primary signification of certainty) is a term with two meanings. Strictly speaking, it is an attitude of the mind towards Truth, and hence may be defined the firm adhesion of the mind to a *true* proposition

without fear of error. Hence again subjective certainty is in this restricted sense necessarily conjoined with truth. But subjective certainty in its wider sense is that mental act or state of mind in which we are free from doubt, and firmly adhere to the object of our mental act; or, more shortly, a firm adhesion of the mind to its object without any fear of error; and that object is distinctly specified by St. Thomas when he defines certainty as "that state of the mind, in which it adheres to any judgment without fear of its opposite."[4]

Subjective certainty is therefore, in this wider sense, evidently neither synonymous with, nor by any means always conjoined with truth, for the patent reason that it is an adhesion of the mind to what is, in its very nature, fallible. Supposing someone were to call this in question, and to say that we cannot be subjectively certain of what is not true, we can answer him thus: Our proposition, that subjective certainty is not necessarily conjoined with truth, is either true or false; supposing it for the sake of argument to be false, our subjective certainty that it is true would prove it to be true, because we adhere to the judgment, of which the proposition is the sign, without any fear of error. Examples of adhesion to false judgments might be multipled *ad infinitum;* and our own daily experience proves only too surely that we are subjectively certain, *i.e.*, internally sure we are right, when we are actually very wrong indeed. Such adhesion to false propositions may be called a false assurance of certainty in con-

4 In lib. iii. *Sent.* disp. xxvi.

tradistinction to subjective certainty strictly so called, which necessarily connotes truth.

That ignorance, doubt, and opinion are, like certainty in its wide meaning, attitudes of the mind with respect to error as well as to truth, is almost too obvious to call for mention; but it may be useful to advert to the reason, which is that conceptual truth, of which alone we are now treating, resides in the judgment, and so does error. Ignorance of error speaks for itself; as there are many truths of which I am not cognizant, so too is my mind a blank with regard to many errors. And when, in doubt, we are placed between two contradictories, and suspend assent for fear of falling into error, we are in a neutral if not negative position with regard to each contradictory, and of two contradictories we know that one must be false. Opinion likewise, considered subjectively, inclines to error as well as to truth, either because we are blind to the reasons for the true proposition, and think we have reasons for its opposite; or because in weighing the reasons for each of the opposite opinions, personal motives incline us to accept as genuine the fictitious cogency of reasons for holding a false opinion. If experience proves that assurance of certitude can attach itself to erroneous judgments, much more, from the very nature of the case, is opinion likely to be sometimes allied with error. We pass next to consider the different

III. Kinds of Certainty. We have seen that Certainty, though fundamentally subjective, is often applied in a secondary sense to the object of certitude; *e.g.*, nothing is more common in ordinary conversation than the expression, "You may take that

for a certain fact," and other similar phrases. Considered **objectively** then, Certainty is **absolute** when a proposition is unconditionally certain and unconditionally excludes its contradictory; **hypothetical,** when a proposition is only conditionally certain, and so only excludes its contradictory under certain conditions. Further, objective certainty is **metaphysical** when the contradictory of the certain proposition is intrinsically impossible because involving an intrinsic contradiction, *e.g.*, the whole is greater than its parts, is metaphysically certain because its contradictory is intrinsically impossible; hence a proposition that is metaphysically certain is unconditioned and necessary. A proposition is **physically** certain when its contradictory is physically impossible, because opposed to the laws of nature, which are conditioned by the will of God; and a proposition is **morally** certain when its contradictory is morally impossible because opposed to the general and constant experience of mankind, which is conditioned by the will of God remotely, and by the will of man proximately. So much for Certainty as a quality of propositions. We have now to regard it **subjectively,** that is to say, as a quality of the mind, or **as Certitude.**

Passing by, as already sufficiently exlpained, the distinction between true and false certainty, we find that subjective, like objective certainty, may be:

(1.) (a.) Metaphysical; (b.) Physical;
(c.) Moral. Moreover, it may be:
(2.) (a.) Natural; (b.) Scientific:
(3.) (a.) Natural; (b.) Supernatural.

(1.) The internal conviction that we are right may have three separate bases, viz.:

(a.) I may think that the contradictory of the proposition I hold to be true, is absolutely and wholly false, as opposed to the very nature of things; and then I have **metaphysical certainty,** which is unconditioned, and admits of no exception. I am metaphysically certain that a just man cannot at the same time be unjust, that men are rational animals, that a whole is greater than one of its parts, etc.

(b.) Or I may think that the contradictory of my proposition is false because opposed to the laws of nature, *i.e.*, of external material nature; and then my **certainty** is **physical,** and conditioned by the First Cause of those laws, *i.e.*, by God Himself, Who can interrupt their uniform course either directly, as He does in miracles, or indirectly by the counter-action of some other natural law. Thus, when General Gordon was in the Soudan, I was physically certain that he was not at the same time in St. Louis; though, if he had had the miraculous gift of bilocation, he might have been in both places at once. And the son of Tobias was physically certain that the person with whom he was travelling was a mortal, and he had no apprehension of the contrary, although the person was really an angel in human form.

(c.) Or I may think that the contradictory of my proposition is false because the whole experience of mankind is against it, or because such things never do happen (though they might do), or because it is improbable, so utterly improbable

as to amount in practice to impossibility; and then I have a **moral certainty,** conditioned not merely by the Divine, but also by the human will, and so not free from exceptions. In actual usage the term Moral Certainty is generally taken to mean the highest degree of probability, and so propositions are called certain, which are in point of fact merely opinions, though opinions for which there is every sort of probability. This is one of many instances in which the boundary-line between two kinds of mental acts is so exceedingly fine, that it is hard to tell when it has been overpassed. But I am morally certain, in the real signification of the term, that the Turkish army is not at present landing on the coast of England, and that the English will not willingly yield Gibraltar, though there is nothing either in the nature of things or in the physical laws of the world to make me think either proposition impossible.

This examination of its separate bases points clearly to the conclusion that subjective certainty must admit of degrees; yet degrees may at first sight appear incompatible with the nature indicated by its definition. This incompatibility, even if apparent, is not real. Recalling the definition of Subjective Certainty in its wide meaning, viz., a firm adhesion of the mind to its object without any fear of error, we see that there is in it a double element—a negative and a positive element. The negative element consists in the exclusion of all fear of error; and in this point lies the essential distinction between certainty and opinion. So far as this negative element is concerned, we cannot

allow of degrees. There is either fear of error or there is not. If there is the slightest such fear, certainty is impossible. But there is a positive element in the definition, viz., the adhesion of the mind to its object. Now here we can, and we *must* admit of degrees; for, if what has been advanced regarding the bases of certainty be true, the adhesion of the mind must be firmer or less firm according to the force of the motive for such adhesion. No one will question that the force of the motive is stronger in metaphysical than in physical, and stronger in physical than in moral certainty; and so the order of degrees speaks for itself.

(2.) Further Subjective Certainty may be natural, or scientific. It is

(a.) **Natural** when we are sure of a thing without having gone through a scientific proof of its truth; *e.g.*, I am naturally certain that the fire which is roaring up the chimney when I come downstairs must have been laid in good time in the morning; I am naturally certain that, if it is a fine afternoon, I shall go out and play cricket.

(b.) **Scientific,** or, as it is sometimes called, Philosophic Certainty, is the kind of certainty we have of a proposition of which we have demonstrated the truth by argument, *e.g.*, Brownson had a scientific certainty of the existence of God when he had proved the truth of this proposition to his own mind by means of argument.

(3.) Natural Certainty has another meaning again, in contradistinction—that is to say—with supernatural. Certainty is

(a.) **Natural** when it is based on natural grounds or motives, or on natural evidence (of which more will be said later on);

(b.) **Supernatural,** when it is based upon a supernatural motive, *i.e.*, the veracity of God Who reveals Himself to us; or upon a supernatural principle, viz., the supernatural light of the gift of faith.

Obviously enough, natural, as opposed to supernatural certainty, and as including the various other kinds of certainty enumerated, is the aspect of the subject of which we are primarily treating; and, as Natural Certainty is based on natural grounds or motives, and is dependent upon natural conditions, they must form the next point of our inquiry.

CHAPTER II.

IV. Sources of Knowledge as media of Truth and motives of Certainty.

IV. Sources of Knowledge, as **Means of attaining Truth,** and as **Motives of Certainty.** A source of knowledge, in general, is that by which, on the one hand, we come to know a truth; and, on the other hand, that by means of which we are certain of the truth we have come to know. Hence the sources of knowledge have a double character and a twofold signification. In their first aspect, as they give us the knowledge of Truth, they are means or more properly *media* of knowledge, and organs or channels through which we know its truth; hence their name of criteria of Truth *per quod*, *i.e.*, instruments by

which we gain Truth. This use of the word "Criterion per quod" must not be confounded with the "Criterion secundum quod," which is the Criterion of Truth properly so called, and will be treated of in the next article. In their second aspect, the Sources of Knowledge, by guaranteeing its truth, and as conditions of its certainty, are the motives upon which we base our certainty of the truths they have communicated to us. This will be made clear by looking at these sources of knowledge separately.

As all our knowledge comes to us through Experience, Reason, and Authority, these must consequently be its three main sources, and the motives upon which all certainty depends. Now

(1.) Experience is twofold, viz.:

(a.) Internal, in self-consciousness;

(b.) External, by means of the external senses:

(2.) Reason, in the wide meaning of the term, acts

(a.) on the one hand intuitively and discursively;

(b.) and, on the other, in what is called "common sense:"

(3.) Authority finally is either

(a.) human; or

(b.) divine.

This gives us in all six sources of knowledge, six channels of truth, six guarantees or conditions of Certainty, which have now to be examined as such. Thus, we shall have first to take each source of knowledge briefly considered in itself as such; next we shall have to ascertain the periphery or extent of the truths we get to know

by its means; after that, we must see how and under what conditions it guarantees the truth of the knowledge it conveys; and lastly, we must show how it is a motive for our certainty regarding such knowledge. We shall see, as we go on, that the proofs adduced have neither the value nor the meaning of real demonstration, which, moreover, is itself a source of knowledge (reason acting discursively), and so cannot serve as a proof of the rest without making the argument either a vicious circle, or begging the question. What has to be done is to show, or rather to explain to what extent the sources of knowledge cannot deceive us under certain given conditions, and thus to make the natural certainty we have of their trustworthiness clear to our own minds, *i.e.*, to make it into a scientific certainty, which is still, be it remembered, natural in contradistinction to supernatural.

Experience.

(a.) **Internal experience, or self-consciousness.** In describing the way in which we form ideas,[1] mention was made of the "sensus intimus," which is the faculty by means of which we know (are conscious of) the internal acts of our physical life both in the sensible and intellectual order, and consequently know both our personal identity and personal existence. The action of this faculty obviously results in self-consciousness, by which we reflect on the first perception of our internal acts, and so become conscious of such perception.

The **truths** we get to know by this means are:

[1] See pp. 10, 11.

(*a.*) internal acts whether sensible or intellectual, *i.e.*, the acts that take place *hic et nunc* within us; not past acts that we recall by means of memory, nor the causes of the present internal acts;

(*β.*) personal identity and personal existence. I know that I exist because I am conscious of myself as a real personal being; and this is the only means by which I possess this knowledge.

As to the **certainty** or **trustworthiness** of this source of knowledge, it does not admit of doubt to any reasonable mind. To such a mind there can be no error or deception in the matter; and the impossibility of such deception is not difficult to explain:

(*a.*) I cannot doubt the certainty of the testimony of my consciousness without at the same time admitting it by the act of doubt; for, if I doubt my existence, for instance, I admit by this very doubt that I exist, for unless I existed I could not doubt. In doubting I presuppose thought, for without thought I could not doubt, and without existence I could not think.

(*β.*) There can only be deception where the known is really different from that which knows. There are many reasons why I may not always apprehend objects distinct from myself, as they really are; but, supposing that men have the use of reason, it is inconceivable that there should be deception where the things known and knowing are in fact one and the same, as in the case of self-consciousness, self being conscious of self.

(b.) **External experience,** by means of the **external senses.** External experience depends upon

the external sense, or sensation, a faculty which hands into our minds the report of the external senses about the qualities or phenomena of which their organs have received the impression.

The **objects** of which we have knowledge by means of sensation are:

(*α.*) External qualities and phenomena of bodies;

(*β.*) rest and motion of bodies;

(*γ.*) the existence of bodies. Only by means of the external senses can we know that bodies exist outside of us. But it must be noted that we only know these external facts by means of sensation in the *relation* in which they stand to us as sentient beings, and according to the impression they thus produce upon us. Hence the appearance of an object depends upon the state of the sense which perceives it, and upon the way in which we apply the sense to it. If, owing to illness or any other cause, a sense is in an abnormal condition, the impression it hands in to be transferred to the imagination as a picture, will be a false one, *i.e.*, it will not correspond to the object it tries to represent. *e.g.*, to the jaundiced all things look yellow; to the deaf clear sounds come confusedly. And a false impression will be produced too if the sense is not attentively applied to its object.

Hence the **trustworthiness** of the senses as sources of knowledge **depends upon certain conditions,** which belong partly to the sense itself, and partly to the judgment formed concerning the object perceived, and based upon its sensible perception. Those which relate to the **sense** are:

(*α.*) The object must be in a right relation to the

sense; *e.g.*—with respect to the eye—it must be neither too near nor too far away, or a too strong or too weak impression will be produced, and lead to deception. Then the medium between the sense and the object must be a congruous one, so that it may not hinder a correct perception. No one, for instance, would put on blue glasses in examining an oil painting, or wear gloves in feeling a person's pulse.

(*β.*) The sense must be sound and in a normal condition, if it is to tell the truth; *e.g.*, a short-sighted person will not see much of the fan-tracery vaulting in Gloucester Cathedral; his defective sight will only take in an indistinct inaccurate impression, unless he remedies the defect by wearing spectacles.

(*γ.*) The application of the sense to the object must be attentive. A cursory glance at Bath Abbey Church, for instance, will not give me a distinctive and so a correct impression of it.

With regard to the **judgment** passed on the object of sense:

(*a.*) We should not judge of an object, nor attribute any quality to it, until we have ascertained that all the necessary conditions for ensuring the trustworthiness of the sense are fulfilled.

(*β.*) We must not extend the scope of the perception of sense beyond its natural limits, *i.e.*, as the senses only perceive the external qualities and phenomena of objects, we cannot, merely from such perception, judge of anything which it does not comprise, *e.g.*, of the nature of the object, or of qualities in it which do not fall under the senses. It is true that further inquiries on such points are

based on the immediate perceptions of sense, but they do not form part of it.

(γ.) Lastly, we must be careful not to consider a sensible quality *as such* to be an essential quality of a body, though it may sometimes prove on investigation to be so; nor should mere appearances be taken for realities until verified as such.

But, above all, sense must be under the control of reason, which has to give to the perceptions of sense their right value and their true signification, and at times to act as their necessary corrective. When this control is neglected, there is sure to be danger of deception by the senses, though its cause is not to be laid solely at their door, but rather must be attributed to reason when she judges of the object of sensation without observing the conditions upon which depends the truth of her judgment.

Taking these conditions for granted, however, the accuracy and **trustworthiness** of the certainty given by the senses, admits of no reasonable doubt; because—

(α.) If, under such conditions, the senses could deceive, the cause of the deception would lie in the sensible perceptive faculty itself, which would thus *by its very nature* fail to answer its end. But this cannot be, for every natural faculty is proportioned to its natural end, and must attain it, if no obstacles are placed in its way, and if it acts in the right manner.

(β.) The same principle applies to the judgment formed on the testimony of the senses. If it is limited to the exact objects of their perception, it cannot deceive, unless on the supposition that the

faculty of judgment does not answer its end, and so by its very nature implies deception, which is obviously absurd; *e.g.*, when I state, on the authority of my senses, that I am writing with black ink on white paper, that there is a cart rumbling in the distance, that someone is scratching away with an unmended quill within a few yards of me, I cannot be deceived if I observe the conditions required in forming all these judgments.

(γ.) The universal belief of mankind, with the exception of some few crotchet-nurses, does not admit of the least doubt of the trustworthiness of the perception of the external senses; indeed people have no surer ground for their certainty concerning acts perceptible to sense, than that they have themselves seen or heard them done.
